(*) Not separately stated prior to Jan. 1, 1923.

## The Metal Market

Sales of all metals are in smaller volume with prices generally holding steady. Metal in the market is used soon after delivery, and there is little of it in speculative hands. Most of the copper producers are holding at either 17.25 cents or 17 cents, delivered, level, but are doing little business. The St. Louis lead market is quiet, with most of the sales for small quantities and for April delivery or shipment, consumers preferring to postpone orders for May requirements as long as possible in the hope of a further weakening of the market.

NEW YORK METAL MARKET PRICES

| | April 11, 1923 Cents per Pound | April 18, 1923 Cents per Pound |
|---|---|---|
| Copper, Electrolytic..... | 17.37½ | 17.00 to 17.25 |
| Lead, Am. S. & R. price.... | 8.25 | 8.25 |
| Antimony.............. | 8.75 | 8.75 |
| Nickel, ingot........... | 30.00 | 28.00 to 30.00 |
| Zinc, spot............. | 7.55 | 7.37½ |
| Tin, Straits............ | 48.00 | 47.50 |
| Aluminum, 98 to 99 per cent.............. | 24.00 | 26.00 to 27.00 |

## March Delinquent Electrical Accounts Show Increase

REPORTS from the National Electrical Credit Association show that in the five sections reporting to the association the March, 1923, delinquent electrical accounts increased over February, 1923. In the Chicago territory the average amount jumped from \$107.49 to \$131.49. For the New York territory in March, 1923, 584 accounts were reported as against 283 in February, 1923, with a total valuation of \$73,655 as against \$36,045. The Philadelphia accounts for March, 1923, were \$204 against \$176 for February of the same year. Conditions in the New England territory for March, 1923, were much better than in March, 1922, since only sixty delinquent accounts were reported as against 129 delinquent accounts for the last year. On the Pacific Coast the number reported for March, 1923, totaled forty-eight against fifteen reported in February, although the average amount for this same period had decreased \$126.12. The March delinquent accounts are as shown in the accompanying table.

DELINQUENT ACCOUNTS IN MARCH

| Branch and Month | Number of Delinquent Accounts Reported | Total Amount | Average Amount |
|---|---|---|---|
| Central Division: | | | |
| February 1922.. | 638 | \$97,311.30 | \$116.12 |
| February 1923.. | 635 | 69,996.47 | 107.49 |
| March 1922.. | 978 | 98,569.53 | 100.79 |
| March 1923.. | 993 | 130,571.90 | 131.49 |
| New York: | | | |
| February 1922.. | 393 | 63,082.00 | 160.00 |
| February 1923.. | 283 | 36,045.00 | 127.00 |
| March 1922.. | 643 | 72,843.00 | 113.00 |
| March 1923.. | 584 | 73,655.00 | 126.00 |
| Philadelphia: | | | |
| February 1922.. | 126 | 16,878.00 | 133.95 |
| February 1923.. | 176 | 26,881.67 | 152.73 |
| March 1922.. | 277 | 28,095.09 | 101.42 |
| March 1923.. | 204 | 26,386.27 | 129.34 |
| New England: | | | |
| February 1922.. | 59 | 5,214.64 | 88.39 |
| February 1923.. | 48 | 2,495.35 | 51.99 |
| March 1922.. | 129 | 11,170.85 | 86.59 |
| March 1923.. | 60 | 4,782.71 | 79.71 |
| Pacific Coast: | | | |
| February 1922.. | 14 | 806.45 | 57.63 |
| February 1923.. | 15 | 4,245.63 | 283.04 |
| March 1922.. | 18 | 2,681.95 | 148.99 |
| March 1923.. | 48 | 7,522.26 | 156.92 |

# The Week in Trade

Prices When Quoted Are Those Reported at the Opening of Business on Monday of This Week for Points West of the Mississippi River and on Tuesday for All Eastern Points

DURING the week increased activities were reported in the market for appliances, especially fans, flatirons and toasters. Large orders for equipment to the utilities are reported in the West and Middle West. Motor sales in New England are said to be twice as satisfactory as one year ago, with this ratio applying even to the smaller producers. Replacements and increasing construction are doing much for lamp distributors. The fixture market is improving with much intensive selling effort. Collections throughout the country are unimproved.

**Boston** Little change in conditions is apparent, business holding its own in nearly all lines. Wire is moving very actively as the construction season develops and prices have stiffened in flexible armored conductor and high-tension insulators. Shortages continue in radio tubes, and the arrival of rigid conduit is delayed in some cases by railroad terminal congestion. Appliance sales are doing well, and heating pads are making new records in production. Motor sales in this territory are certainly twice as satisfactory in volume as a year ago, and this ratio applies even to the smaller producer. The upward pressure of prices is almost continuous. General business in New England is excellent, barring some retail slumps due to poor weather. The great industries of this section are intensively active. Financial conditions are well in hand.

**New York** Steady demand is the feature of a market of slightly increasing prices and unusually even stocks. Several decreases in prices of wire, devices and radio are expected at the end of two weeks because of lower raw-material costs. Orders for fans are being promptly filled, and jobbers are most optimistic about the season's possibilities. Conduit stocks are much improved. Collections are only fair.

**Atlanta** Spring weather is ushering in a large amount of additional outdoor work of various types and a shortage in crude labor is beginning to be felt. Skilled labor, while fully employed, still seems to be sufficient for demands, but there is no excess in the territory. Industrial establishments generally are on full or overtime operation, with the outlook excellent for a continued activity throughout the summer and early fall. Rains are preventing the planting of cotton, and this is causing some uneasiness in the rural communities. Electrical dealers report their business as good, particularly in building and line materials. Shipments on conduit have improved and stocks are better.

**Pittsburgh** The activity among the industrial companies is especially noticeable. Increased buying is being done by them in the electrical line, requisitions becoming larger. It is reported that one industrial firm bought electric tractors during the week to the amount of \$100,000. There is a decided increase during the week on armored cable and a slight increase on some conduit fittings. There was a slight drop in copper, although this has not as yet had any effect upon wire prices.

**Cleveland** The week has been a favorable one for jobbers, who report sales far in excess of the same period last year. Stocks are in good shape except for those products containing copper. Manufacturers are most concerned about the labor scarcity and the increasing costs of production. Prices are advancing slightly on lamp cord, weatherproof wire, conduit, tape, porcelain, transformers, insulators and switch boxes. Appliances are in fair demand and central-station expansion continues satisfactorily.

**Chicago** Business has remained quite active, with several announcements of increased prices. Flexible armored conductor increased \$5 per 1,000 ft. and connecters increased \$3 per 1,000. Motors rated at 250 hp. and above have increased 10 per cent. It is extremely difficult to obtain 1½-in. locust pins, since this size is almost entirely depleted. Building permits issued the first week in April amounted to \$21,996,000, or nearly \$5,000,000 more than in the whole month of April, 1922.

**St. Paul-Minneapolis** Jobbers say business is slow. The brisk buying of the winter months on a rising market has stopped. Construction in both cities continues excellent. Minneapolis construction is fair, but several large projects have been postponed because of high prices. The big radio and appliance exposition at the Minneapolis armory is drawing large crowds.

## Demand, Supply and Price Trend of Nineteen Commodities as Sold in Sixteen Cities

Explanation:
Demand: Steady, Slow or Active
Supply: Normal, Low or High
Price Trend: Firm, Decreasing or Increasing

Next Week Reports will include Instruments, Farm Lighting Plants and Irons

**St. Louis** Activities in the building industry are being well sustained. The building permits for the month of March amounted to $4,237,585, which is an increase of 136 per cent over the same month in 1922. The car shortage has been improved by the reduction of bad order equipment and the delivery of new cars. In electrical lines jobbers report large stocks of conduit boxes. There has been a slight increase in some of the prices of schedule material, and increases are looked for in several other lines before very long. The sale of electrical appliances for the first quarter of the year has been more than 30 per cent greater than during the same period in 1922. Collections in retail circles are much improved.

**Denver** Business is good, though conservatism and caution are being exercised in placing of orders. Industrial plants are temporarily leading the field in new electrical business. Prices in nearly all lines are strengthening. Appliances and lamps are moving steadily. Range business in the Arkansas Valley is booming.

**Portland-Seattle** Construction continues active, and electrical permits for the first three months of this year were appreciably greater than for 1922. Most stocks are in very satisfactory shape, although Seattle still reports a shortage of conduit. Slight price increases were noted in a number of lines and further advances are expected. Labor is scarce and wages are increasing. Radio demands are decreasing in the cheaper sets, but the better-class sets continue active.

**San Francisco** Contractors' and jobbers' staffs are going at top speed, every available electrician is working, and several jobbers have increased their sales forces. Dealers' business is markedly better, especially in radio material and small heating appliances. Several big orders and inquiries are reported, such as for $50,000 worth of cross-arms from a power company, several 10,000 socket and plug orders from local manufacturing plants, 50,000 ft. assorted lamp cord and about $2,500 worth of safety switches.

# Activities of the Trade

Devoted to News of the
Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Phoenix Light Company Sales Made Large Increase

Negotiations have been closed by the Phoenix Light Company, Milwaukee, for 20,000 sq.ft. of additional factory space at 531 Market Street, adjoining the company's present plant. The building consists of four stories and basement and will house the lamp department.

Company officials report an increase of 56 per cent in sales for the first quarter of 1923.

## American Insulated Wire & Cable Now Making Magnet Wire

The American Insulated Wire & Cable Company, Chicago, is now manufacturing magnet wire, having begun operations April 1. Its products are sold under the trade name "A-1 magnet wire" and consist of the following: Plain-enameled, single-cotton-covered, double-cotton-covered, single-cotton-enameled, double-cotton-enameled, single-silk-covered, double-silk-covered, single-silk-enameled and double-silk-enameled.

A factory manager has been engaged who has had twenty years' experience in this field and has developed magnet wire for two of the largest companies in the United States making this product. During that period he has supervised the production of upward of 60,000,000 lb. of magnet wire to meet every condition in use. He has both technical and practical knowledge of the uses of wire as well as of its manufacture.

## Westinghouse Receives Milwaukee Power Transformer Order

The Milwaukee Electric Railway & Light Company has ordered nine power transformers from the Westinghouse Electric & Manufacturing Company.

The order included one 3,000-kva., OIWC-SC three-phase, 60-cycle transformer of 27,600 volts and 13,800 volts high tension, 2,300 volts low tension, to have 2,200 kva. capacity without water in the cooling coils; two 3,000-kva. OISC three-phase, 60-cycle transformers, 27,600 volts and 13,800 volts high tension, 2,300 volts low tension; two 2,000-kva. OISC three-phase, 60-cycle transformers, 27,600 volt and 13,800 volts high tension and 2,300 volts low tension, and four 1,667-kva. OISC single-phase, 60-cycle transformers, 132,000 volts star high tension, 27,600 and 13,800 volts low tension.

The first five transformers are for substation use, to step down from the 27,600-volt network of the company to 2,300-volt circuits. The others are part of the equipment required for establishing a 132,000-volt line and connecting it to the 27,600-volt system at different points.

## Superior Switchboard Absorbs Meter Devices in Expansion

The Meter Devices Company and the manufacturing division of the Electric Motor & Engineering Company have been absorbed by a new corporation called the Superior Switchboard & Devices Company, Canton, Ohio.

The Superior Switchboard & Devices Company is moving into a new factory building with approximately six times the floor space of the old building. The executive personnel of the Superior Switchboard & Devices Company will be practically the same as was formerly connected with the Meter Devices Company and the manufacturing division of the Electric Motor & Engineering Company.

This change in name and location allows for an expansion that was needed. The Superior Switchboard & Devices Company will manufacture switchboards, panelboards, power-meter testing devices, steel boxes and kindred articles.

## Chain Battery System Moves Plant to Kansas City

The Chain Battery System, a company manufacturing storage batteries, has recently moved its plant and headquarters from Carthage, Mo., to Kansas City, where it has purchased a brick building at 1321 Virginia Avenue which is to be used as a factory. This company, which also is a wholesale distributor, is two years old and has assembling plants in Wichita and Chanute, Kan.; Carthage and Springfield, Mo.; Tulsa, Okla., and Fort Smith, Ark. C. E. Nordyke is its president.

## Western Electric to Build New $1,000,000 Warehouse

The Western Electric Company announced last week its intention to build a new merchandise building at its Hawthorne works in Chicago at a cost which is expected to be well in excess of $1,000,000. The new building will supplement the warehouse facilities at that plant and relieve a situation which has forced the company to rent 200,000 sq.ft. of storage space in buildings outside its Chicago plant.

The new structure will be four stories high and will have a floor space of 100,000 sq.ft. Ground will be broken within the next six weeks and the warehouse will be ready for use by early autumn.

## S. A. Woods Machine Company Enlarges Line

Increasing demand for motors is reported by M. F. Fitch, sales manager motor division, S. A. Woods Machine Company, Boston, business now running well over 50 per cent above that of a year ago. During the past few months the company has purchased and installed a number of additional machine tools, thereby increasing the proportion of motor production space allotted to this department, and additional employees have been engaged.

Mr. Fitch stated last week that foreign orders are increasing, notably from Japan, China and Australia. The company has been able to keep in line with the demand by careful advance ordering of raw materials and has lately increased its line to include motors up to 50 hp. rating. Some improvements in design are announced, and the outlook for the year is most favorable.

## G. E. Orders for First Quarter Show Gain of 56 per Cent

Orders received by the General Electric Company for the three months ended March 31 amounted to $80,010,045, according to an announcement just made to stockholders by President Gerard Swope. This is an increase of 56 per cent over a similar period last year, when orders totaled $51,335,300.

The International General Electric Company, Inc., reports net sales of $20,212,257 during 1922, against $38,359,012 in 1921. Despite the sharp falling off in total income, the profits for the year were larger than 1921. Net profits for the year totaled $2,265,477, which, after allowing for preferred dividends, left a balance equal to $15.65 a share on the $10,000,000 capital common stock outstanding, against $12.73 a share in 1921.

| | 1922 | 1921 |
|---|---|---|
| Net sales | $20,212,257 | $38,359,012 |
| Other income | 1,196,028 | 2,581,649 |
| Total income | $21,408,285 | $40,940,661 |
| Cost of sales, expenses and taxes | 18,803,944 | 37,714,544 |
| Interest | 338,864 | 1,254,044 |
| Net income | $2,265,477 | $1,973,073 |
| Preferred dividends | 700,000 | 700,000 |
| Surplus | $1,565,477 | $1,273,073 |

The balance sheet on Dec. 31, 1922, reported net current assets of $9,258,440 and net current liabilities in the form of notes and accounts payable of $4,715,240.

## Robbins & Myers Open New Sales Office in North Carolina

The Robbins & Myers Company, Springfield, Ohio, manufacturer of electric motors, generators and fans, has opened a new sales office in Charlotte, N. C., 217 Latonia Building.

Albert Milmow has been placed in charge of this office. Mr. Milmow has had many years' experience with electrical equipment and is a specialist in the textile field.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

Purchase and agency is desired in New Zealand (No. 6,018) for small electrically driven refrigerators having a capacity up to one-eighth of a ton, direct-current, self-acting and self-contained, for use in private residences and hotels.

Purchase and agency is desired in Mexico (No. 6,019) for a small automatic electric machine for grinding ice and filling glasses, the placing of the glass making the electrical connection.

Purchase is desired in South Africa (No. 6,020) of lighting fixtures, electrotherapeutic equipment and signal system of sanitarium.

HADJI BEY ET CIE, McCurtain Street, Cork, Ireland, would like to receive catalogs of electrical novelties, mechanical figures, etc., for window display in a confectionery establishment.

PROPOSED EXTENSION TO THE HAVRE ELECTRIC SYSTEM.—The Société Havraise d'Energie Electrique has secured a fifteen-year extension of its concession to supply electrical service in Havre. A number of extensions are contemplated, including the installation of a 30,000-volt distribution cable connecting the station at Havre with the plant at Zainville, additions to both power stations, and erecting a telephone line connecting up the power houses and substations. The company will increase its capital stock from 25,000,000 francs to 45,000,000 francs to finance the work.

ELECTRIC SYSTEM FOR BATHURST, AUSTRALIA.—Permission has been granted the Municipal Council of Bathurst, New South Wales, Australia, to appropriate £40,000 for the installation of an electric system for the city, on which work will begin at once.

POWER PLANT FOR THE PROPOSED SUGAR MILL IN BRISBANE, AUSTRALIA.—Plans for the proposed sugar mill to be erected by the state government in the Tully-Banyan district, to cost about $2,000,000, include a power plant. The Australian Sugar Producers' Association is interested in the project.

AUXILIARY STEAM PLANTS NEEDED IN JAPAN.—As the hydro-electric companies in Japan have awakened to the fact that their present systems are inadequate to meet the demands at all times without auxiliary steam power stations, *Commerce Reports* states, there should be a good demand for equipment for steam-power plants. Shortage of water has become an annual problem in Japan, and for this reason it is recognized that an auxiliary steam-power plant is necessary for practically all hydro-electric plants if the companies are to be able to fulfill their contracts.

## New Apparatus and Publications

SLOTTING MACHINE.—The Martindale Electric Company, Box 35, Station C, Cleveland, has placed on the market a new commutator slotting machine.

ELECTRIC PUMP JACK.—An electric pump jack which will convert the ordinary farm pump into an electric pump is manufactured by the Cullman Wheel Company, Chicago.

FLOOR-GRINDING MACHINES.—The Campbell Machinery Company, Wollaston, Mass., is manufacturing a floor-grinding and polishing machine.

ELECTRIC WAX POT.—An electrically heated wax pot has been placed on the market by the Acme Electric Heating Company, Inc., 1217 Washington Street, Boston.

TURBO-GENERATOR SETS.—Bulletin No. 21 issued by the Wellman Turbine Company, Oshkosh, Wis., covers the "Wellman" turbo-generator units.

TURBO-BLOWER.—The Wellman Turbine Company, Oshkosh, Wis., is distributing bulletin No. 10, describing the "Wellman" undergrate turbo-blower.

PLURAL PLUGS.—The Benjamin Electric Manufacturing Company, 847 West Jackson Boulevard, Chicago, is distributing a circular covering the use of six plural plugs.

HAND SHAPER.—The R. L. Carter Company, Syracuse, N. Y., has recently placed on the market a hand-type shaper for the woodworker, designed to use with a 1/9-hp. Westinghouse motor.

HIGH-TENSION SWITCHES.—The Pacific Electric Manufacturing Company, 827 Folsom Street, San Francisco, has issued three bulletins, Nos. 1,401, 1,500 and 1,600, covering its various types of high-tension switches.

GRAPHIC INSTRUMENTS. — "Some Things Being Done With Graphic Instruments" is the title of bulletin No. 223 issued by the Esterline-Angus Company, Indianapolis, Ind.

OUTDOOR EQUIPMENT.—Schweitzer & Conrad, Inc., 4435 Ravenswood Avenue, Chicago, is distributing bulletin No. 202, describing the "S & C" high-voltage outdoor equipment.

BATTERY-CHARGING OUTFITS.—The Hobart Brothers Company, Troy, Ohio, is distributing leaflets covering the "HB" eight-hour constant-potential battery-charging outfit and the new "HB" 300-amp., 7½-15-volt outfit.

## New Incorporations

THE ATKINS LIGHT & POWER COMPANY, Marion, Va., has been incorporated with a capital stock of $10,000. The officers are: C. P. Shrock, president, and S. T. Crowe, secretary.

THE GLENVILLE (W. VA.) ELECTRIC COMPANY has been incorporated by C. W. Marsh, W. T. Smith, B. W. Craddock, Guy Stalnaker, J. Craddock and G. Smith, all of Glenville. The company is capitalized at $15,000 and proposes to supply electricity for lamps and motors in Glenville.

THE FARMINGTON RIVER HYDRO-ELECTRIC CORPORATION has filed articles of incorporation under the laws of the State of Delaware for the purpose of constructing two hydro-electric plants on the Farmington River. The officers are: L. B. Dow, New Boston, Conn., president; H. W. Ward, vice-president, and R. P. Ward, secretary and treasurer.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

CALAIS, ME. — The Hollingsworth & Whitney Company, 185 Devonshire Street, Boston plans to build a power plant in connection with its proposed local paper mill, to cost about $250,000.

PORTLAND, ME.—The Portland Terminal Company, a subsidiary of the Maine Central Railway Company, plans to build a power house in connection with its proposed car repair shops at South Portland, to cost about $1,500,000.

BOSTON, MASS.—Plans have been prepared by the Department of Public Works for a new fire-signal station to be erected on Boylston Street and also for changing the fire-alarm system throughout the city. The cost is estimated at about $500,000.

GREENFIELD, MASS.—The Greenfield Electric Light & Power Company is planning to install a new distributing and switching station on its Mill Street property.

WORCESTER, MASS.—The Worcester Electric Light Company plans to place about 3 miles of its overhead wires underground this season in various sections of the city, in accordance with its agreement with the city.

NEW BRITAIN, CONN.—The Farmington River Power Company will soon begin work on two new hydro-electric plants on the Farmington River, near New Boston, for the Farmington River Hydro-Electric Corporation, recently organized, to supply electricity in this section of the state. One development will include three dams, reservoirs and a 4,000-hp. plant to operate under a 300-ft. head, and the other a dam, pipe line and power station of 3,600 hp. operating under a 150-ft. head. The proposed plant will supply energy in New Hartford and vicinity. L. B. Dow, New Boston, is president.

SOUTH NORWALK, CONN.—Plans are being prepared by Westcott & Mapes, Inc., New Haven, architect and engineer, for an addition to the municipal lighting plant, to cost about $300,000.

## Middle Atlantic States

AMSTERDAM, N. Y.—The Adirondack Power & Light Corporation contemplates the erection of a high-tension transmission line from the Rotterdam distribution station to North Albany substation (18 miles), to cost $23,500 per mile.

MEDINA, N. Y.—The Western New York Utilities Company, Inc., expects to install a General Electric 3,200-kva., three-phase, 25-cycle, 115,000-volt vertical unit at its Waterport plant. G. W. Ide is manager.

NEW YORK, N. Y.—The United Electric Light & Power Company is taking bids for an addition to its Hell Gate electric plant.

ROCHESTER, N. Y.—Extensions and improvements are contemplated by the Rochester Gas & Electric Company during 1923, including a new substation and equipment in congested district, substation and equipment at western city line for industrial district, enlarging main steam station No. 3, and installing one 15,000-kw. turbine, new switchboard and other equipment, and extension to distribution and transmission systems. The cost is estimated at $3,060,477. Thomas H. Yawger is general superintendent.

ROME, N. Y.—Electric power equipment will be installed in the proposed addition to the plant of the Rome Brass & Copper Company, to cost about $175,000. A. F. Pashley, 431 South Dearborn Street, Chicago, is architect.

LAKEWOOD, N. J.—The Lakewood & Coast Electric Company contemplates extensions and improvements to its system.

ANNVILLE, PA.—The Annville & Palmyra Electric Light Company plans to rebuild all secondary lines in Palmyra. D. K. Bomberger is manager.

BETHLEHEM, PA. — Electric power equipment will be installed in the new five-story cold-storage, refrigerating and packing plant to be built by the Confederated Home Abattoirs Corporation, 314 American Casualty Building, for which bids will be received until May 15.

COLFAX, PA.—The Duquesne Light Company, Pittsburgh, is taking bids for the construction of an addition to its local generating plant, to cost about $500,000.

GIRARDVILLE, PA. — Extensions and improvements are contemplated by the Schuylkill Electric Company, including the construction of a 1,000-kw. substation (direct current) for railway service for the Schuylkill Railway Company, the installation of 120 series street lamps in West Mahoney Township and 25 series street lamps in Butler Township. Transmission voltage will be changed from 2,300 to 6,600 volts to Centralia and Lost Creek. Two outdoor substations, one of 400 kva. and the other 300 kva., will be erected. Emery Stern is electrical engineer.

HARRISBURG, PA.—The Harrisburg Light & Power Company plans extensions and improvements to its system to cost $700,000.

MIDDLETOWN, PA.—Officials of the Metropolitan-Edison Company, Reading, have organized the Metropolitan Power Company to construct and operate the steam-driven electric plant to be built on the Susquehanna River here. The first unit will have a capacity of 30,000 kw. and will cost about $1,000,000. The cost of the entire project is estimated at $3,000,000.

PHILADELPHIA, PA.—A power house will be erected at the plant of the Modern Laundry Company, Forty-first and Filbert Streets. William Lowenthal, 1208 Chestnut Street, is architect.

PHILADELPHIA, PA.—Bids will be received by the Department of Public Works, City Hall, until April 25, for electrical equipment for the Northeast Sewerage Treatment Works.

PHILADELPHIA, PA.—Electric power equipment will be installed in the proposed plant to be erected at Water and Bainbridge Streets by the American Bag & Paper Company, Second and Vine Streets, to cost about $550,000.

READING, PA.—Plans are under way for the installation of electric pumping ma-

chinery in connection with a proposed filter plant at the municipal waterworks.

SPARTANSBURG, PA.—The Spartansburg Oil & Gas Company, plans to build a substation at its proposed local oil refinery, to cost about $130,000.

SPRINGDALE, PA. — Electric power equipment will be installed in the proposed addition to the plant of the Heidenkamp Plate Glass Corporation, to cost about $500,000.

BALTIMORE, MD.—The Standard Sanitary Manufacturing Company, Bessemer Building, Pittsburgh, Pa., will build a power house in connection with its proposed plant, on Fifth Avenue, to cost $2,000,000.

BECKLEY, W. VA.—The Beckley Electric Light & Power Company contemplates the installation of an ornamental lighting system in the business district (about sixty lamps), erecting a new office building on Heber Street and purchasing a new compressor for the water plant. Charles C. Farmer is secretary.

MARTINSBURG, W. VA.—The United Steel & Car Company, recently organized, will build a power house at its proposed local plant, to cost about $1,000,000. F. Vernon Aler represents the company.

SUMMERSVILLE, W. VA.—W. H. Campbell & Son, owners of the local electric plant, contemplate the construction of a new electric plant. As yet details have not been decided upon.

FRANKLIN, VA.—A 13,000-volt transmission line is now being erected from the municipal electric plant to the town of Boykins, a distance of 21 miles. J. B. Lynch is superintendent of distribution.

NEWPORT, VA.—The Chesapeake & Ohio Railroad Company contemplates building a power plant in connection with its proposed locomotive and car repair shops, to cost $750,000. C. W. Johns, Richmond, is chief engineer.

YORKTOWN, VA.—The Bureau of Yards and Docks, Navy Department, Washington, D. C., will soon take bids for the installation of equipment at the local power plant (Specification 4,826).

WASHINGTON, D. C.—Bids will be received by the Chief of Air Service, United States Army, until April 23, for 150 switch assemblies and 150 switch panel assemblies (Circular 23-138).

## North Central States

ALMA, MICH.—An additional 100-hp. or 150-hp. oil-engine-driven unit may be purchased for the municipal electric light plant. E. E. McKee is city clerk.

GRAND RAPIDS, MICH. — The Père Marquette Railroad Company plans to build a power plant at its Wyoming shops, to cost about $500,000.

KALAMAZOO, MICH. — Electric power equipment will be installed in the proposed addition to be erected by the Kalamazoo Paper Box Company, to cost about $200,000. Billingham & Cobb, Press Building, are architects.

LEXINGTON, MICH.—Plans are under consideration to connect the municipal system with the lines of the Great Lakes Power Company, Sault Ste. Marie, Ontario, Canada. W. Hatton is manager.

ZILWAUKEE, MICH.—The Consumers' Power Company, Jackson, has surveys in progress for its proposed 100,000-hp. steam-driven electric plant. The cost is estimated at $500,000.

CLEVELAND, OHIO.—Bids will be received at the office of the commissioner of purchases and supplies, City Hall, Cleveland, until April 27 for distributing transformers for the division of light and power.

TORONTO, OHIO.—The Ohio & Pennsylvania Power Company contemplates building a power plant here to cost about $1,000,000. A transmission line will be erected.

LOUISVILLE, KY.—The Louisville Gas & Electric Company contemplates erecting a substation at Thirteenth and Magazine Streets, to cost about $150,000.

EVANSVILLE, IND.—Plans for the proposed local car and locomotive shops of the Chicago & Eastern Illinois Railroad Company include a power house. The cost is estimated at $1,000,000.

INDIANAPOLIS, IND. — Bids will be received by the Board of Sanitary Commissioners, Sanitary District of Indianapolis, City Hall, until April 24 for construction of dehydration building and furnishing equipment of section 5, division III, for the sewage-disposal plant, including electric wiring, stokers, coal storage and handling equipment, conveyors, fans and motors, traveling cranes, etc. Charles H. Hurd, Merchants' Bank Building, is consulting engineer.

VINCENNES, IND.—The Blackford Window Glass Company plans to build a power house at its new local plant, to cost about $1,000,000.

DURAND, WIS. — The Durand Light & Power Company is planning to raise its power dam at Eau Galle.

GALESVILLE, WIS.—The Davis Mill & Electric Company contemplates erecting some farmer lines this year. B. W. Davis is manager.

GREEN BAY, WIS. — The Wisconsin Public Service Corporation plans to start work on another large hydroelectric development at Caldron Falls on the Peshtigo River, to cost about $750,000.

IRON RIVER, WIS. — The Iron River Light & Power Company contemplates building a new hydro-electric plant this year, to cost about $400,000.

MENASHA, WIS.—The Municipal Electric and Water Department contemplates the purchase of equipment for changing the distribution lines from 2,300, delta, three-phase, to 2,300/4,000 star, three-phase, fireproofing plant building and installing additional water-pumping machinery. J. H. Kuester is superintendent of distribution.

LITTLE FALLS, MINN. — Plans have been prepared by the Little Falls Power Company for a hydro-electric development in the Mississippi River, to cost about $100,000. The project will include two dams and power house.

CEDAR ROCK, IOWA.—The Iowa Electric Company has been granted a franchise to erect a hydro-electric plant on the Wapsipinicon River, near Big Rock, this summer.

FORT DODGE, IOWA.—The Fort Dodge Gas & Electric Company contemplates replacing all gas lamps with electric lamps during the year. M. Anderson is manager.

MUSCATINE, IOWA. — The date for receiving bids for the construction of the municipal electric plant and distribution system has been extended from April 18 to April 25 by the board of electric light trustees. A. I. Mullergren, Gates Building, Kansas City, Mo., is consulting engineer.

NEOLA, IOWA.—The installation of an additional generating unit in the municipal electric light plant and establishing a twenty-four hour service is under consideration. E. L. Stinn is superintendent.

HOUSTON, MO.—The Houston Electric Light & Power Company expects to build a new dam and will probably install a new waterwheel and repair transmission lines. J. A. Johnston is president.

JASPER, MO.—Bonds to the amount of $40,000 have been voted for the installation of a municipal electric plant and waterworks.

LANAGAN, MO. — The Indian River Power Company will erect a transmission line to furnish electricity to the Elk Springs, Ginger Blue Lodge and Kansas City (Kan.) Boy Scouts' Camp. William Christensen is superintendent.

GRAND FORKS, N. D.—The Red River Power Company contemplates the erection of about 28 miles of transmission lines, to cost about $30,000.

STARKWEATHER, N. D.—The Northern Utilities Corporation contemplates the installation of a large fuel-oil storage tank. F. R. Irons is manager.

VALENTINE, NEB.—The Cornell Hydro Electric Company is considering the installation of an oil engine (stand-by) unit. P. S. Hyatt is manager.

EUREKA, KAN.—Bids will be received by the city clerk until April 24, for the installation of an ornamental lighting system.

KANSAS CITY, KAN. — The Atchison, Topeka & Santa Fe Railway Company, Chicago, plans to build a power house in connection with its proposed local locomotive and car shops, to cost about $300,000.

KANSAS CITY, KAN.—Electric power equipment will be installed in the oil-refining plant to be erected by the Sinclair Refining Company, 111 West Washington Street, Chicago, to cost about $500,000.

WICHITA, KAN. — The Roxana (Ill.) Petroleum Company, will build a power house in connection with its proposed local refining plant, to cost about $3,500,000.

## Southern States

BOONE, N. C. — An electric generator, switchboard and other equipment will be installed at the power house at the Appalachian Training School.

CARTHAGE, N. C.—Surveys are being made by the Smitherton Power Company, Troy, for proposed power development and dams on Drowning Creek, Moore County. The company will ultimately build a cotton mill on the creek.

DANBURY, N. C.—Pepper Brothers contemplate building a hydro-electric plant in connection with a new grain mill, to cost about $90,000.

MOORESVILLE, N. C.—Bids will be received by the Mayor and Board of Town Commissioners until May 7 for improvements to waterworks, including pumping station, auxiliary station, 5 miles of 2,200-volt transmission line, motor-driven centrifugal pumps and accessories, filter-plant equipment, etc. The Gilbert C. White Company, Durham, is engineer.

RED SPRINGS, N. C. — Bonds to the amount of $56,000 have been sold, the proceeds to be used for the installation of a lighting system and other municipal improvements.

KINGSTREE, S. C.—The Kingstree Electric Light & Ice Company will make extensions to its transmission lines and install a new oil engine this summer. F. B. Adams is manager.

EATONTON, GA.—The Putman Mills & Power Company contemplates the construction of a new power plant, to cost $70,000.

CRESCENT CITY, FLA.—Bids will be received by the Board of Bond Trustees until May 14 for the installation of a 100-hp. Diesel or semi-Diesel engine and an alternating-current generator for direct connection to engine, together with exciter and switchboards. C. H. Preston is chairman.

CLARKSVILLE, TENN.—The Kentucky Public Service Company contemplates installing equipment for emergency service. Energy to operate the local service is supplied from the Hopkinsville plant. E. H. Allen is local superintendent.

MEMPHIS, TENN.—The installation of an ornamental lighting system on Union Avenue is under consideration.

MEMPHIS, TENN.—The Memphis Power & Light Company has arranged a fund of $3,400,000 for extensions in plants and transmission system during the present year.

TREZEVANT, TENN.—The installation of an electric lighting system and waterworks, to cost about $35,000, is under consideration.

VICKSBURG, MISS. — The Arkansas Light & Power Company, Pine Bluff, Ark., has acquired the property of the Vicksburg (Miss.) Light & Traction Company. Extensions will be made to the system.

NEW ORLEANS, LA.—The Amalgamated Seaport Petroleum Company, recently formed, will build a power house at its proposed oil refinery, to cost about $1,500,000.

COMANCHE, OKLA.—Plans are under consideration for extending the high-tension transmission line of the municipal electric plant to three small refineries in the near future. E. A. Wine is superintendent.

FAIRFAX, OKLA.—C. I. Huffaker, owner of the local electric plant, expects to install a 300-hp. Fairbanks-Morse & Company engine and generator within the next four months.

PONCA CITY, OKLA. — Bonds to the amount of $140,000 have been voted for extensions to the municipal electric light plant.

SAND SPRINGS, OKLA.—A power plant will be built by the Consumers' Ice Company in connection with a new ice-manufacturing plant, to cost about $75,000.

BRONTE, TEX.—The City Council has granted C. Holder and F. E. Brown a franchise to construct and operate an electric lighting system here.

BURKBURNETT, TEX.—The Burkburnett Electric Company, recently acquired by new interests, contemplates extensions to its system.

COOPER, TEX. — The Cooper Power, Light & Ice Company contemplates rebuilding its distribution lines. E. D. Brodhead is president and manager.

HEMPSTEAD, TEX.—The Western Public Service Company, Colorado Springs, Col., has acquired the property of the Hempstead Light & Power Company and will make extensions and improvements.

FORT WORTH, TEX.—A power plant will be built by the Southwestern Portland Cement Company, El Paso, at its proposed local mill, to cost about $450,000.

JASPER, TEX. — The Jasper Electric Company is planning to install an additional generating unit. Wesley L. Neal is manager.

KERRVILLE, TEX.—The Kerrville Light, Heat & Power Company contemplates installing an oil or Diesel engine-driven unit of about 250 hp., complete with generator and switchboard. S. Eastland is president of the company.

LOCKHART, TEX.—The Citizens' Light & Water Company is considering the construction of an ice plant.

## Pacific and Mountain States

MILLWOOD, WASH.—The Inland Empire Paper Company contemplates extensions to its plant, including the construction of a dam on the Spokane River, to develop power to operate its works.

STAYTON, ORE.—A. D. Gardner has applied for permission to construct a hydro-electric power plant to furnish electricity to a number of local industries.

LONG BEACH, CAL.—Steps have been taken for the installation of an ornamental lighting system on Belmont Avenue.

LOS ANGELES, CAL.—The construction of an automatic power station, 45 ft. x 40 ft., is under consideration by the Los Angeles Railway Corporation.

MODESTO, CAL.—Bids will be received at the office of the Modesto Irrigation District, Modesto, until May 2, for material required in building an electric distribution system within the district. The apparatus to be purchased will include 900 butt-treated poles, hardware for approximately 40 miles of line, 139,500 lb. of copper wire, nine three-pole, 11-kv. switches, four 1,000-kva. and six 160-kva. transformers.

RIVERSIDE, CAL.—The Snowolene Refining Company, Pacific Mutual Building, Los Angeles, plans to build a power house in connection with its proposed oil-refining plant, to cost about $350,000.

SAN FRANCISCO, CAL.—The Electric Metals Company, care of Sanderson & Porter, Nevada Bank Building, consulting engineers, is preparing plants for a 100,000-hp. hydro-electric generating plant on the Klamath River, Siskiyou County, in connection with a metallurgical plant, to cost about $800,000.

SANTA BARBARA, CAL.—Plans are being prepared by Soule, Murphy & Hastings, 1206 State Street, for an orphanage, power house and laundry, to cost about $250,000, for the St. Vincent's Orphanage.

TURLOCK, CAL.—Steps are being taken for the installation of an ornamental street-lighting system. Horace Hall is city engineer.

VENTURA, CAL.—The Seaside Refinery Company will build a substation in connection with a new oil refinery, to cost about $100,000.

ISMAY, MONT.—The Ismay Light & Telephone Company contemplates increasing the output of its plant. Clifford Sweet is manager.

## Canada

BOTHWELL, ONT.—The Lighting Commissioners contemplate a general overhauling of the municipal electric system and installation of new transformers and erecting new wire. E. H. Crompton is secretary.

ORILLA, ONT.—The Water, Light and Power Commission contemplates installing approximately 300 additional street lamps in the town and suburbs and erecting a substation at Atherly. A 2,200-volt line is being erected to Victoria Point. R. H. Starr is chief engineer.

PETERBOROUGH, ONT.—The Peterborough Utilities Commission expects to erect a new main substation this year, to cost about $150,000. W. G. Henderson is secretary.

PORT STANLEY, ONT.—The construction of a steam-power plant at Port Stanley, to cost about $1,000,000 is under consideration by the Hydro-Electric Commission of Ontario.

STURGEON FALLS, ONT.—The Municipal Electric Light Department contemplates changing the street-lighting system from 4.4 amp. series lamps to 6.6-amp. series lamps with constant-load transformers, and also erecting a three-phase circuit throughout the town for power service. L. E. Carter is town engineer.

COATICOOK, QUE.—The Town Council contemplates a 1,200-hp. development under a 90-ft. head this summer. The project will include the construction of a power house and the purchase of electric generating equipment and waterwheel. E. E. Akhurst is superintendent.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued March 20, 1923)

1,449,784. INDUCTION-MOTOR SPEED REGULATION; W. Seiz, Baden, Switzerland. App. filed March 3, 1921. Commutator machine in concatenation with induction-motor secondary.

1,449,800. ELECTRICAL APPARATUS FOR MOTOR VEHICLES; L. M. Woolson, Dayton, Ohio. App. filed July 10, 1918. Mounting of motor on automobile-engine fly-wheel.

1,449,815. MEANS FOR CONTROLLING ELECTRIC SWITCHES; E. C. Gooch, Estes Park, Col. App. filed July 3, 1920. To prevent welding together of automatic closing devices.

1,449,825. STORAGE-BATTERY CONSTRUCTION; W. P. Loudon, Niagara Falls, N. Y. App. filed April 18, 1918. Improved venting plug.

1,449,830. CIRCUIT-CONTROLLING TELEPHONE-RECEIVER SUPPORT; D. M. Miller, Brooklyn, N. Y. App. filed March 18, 1921. Pivoted arm-holding receiver controls circuit.

1,449,833. PROCESS OF REGENERATING LEAD-STORAGE BATTERIES; H. O. Parker, Midland, Pa. App. filed Aug. 13, 1920. Battery filled with a hydroxide and then charged until solution becomes acid.

1,449,834. ROTATING OR OSCILLATING ELECTRIC FURNACE PLANT; A. H. Pehrson, Stockholm, Sweden. App. filed April 11, 1922.

1,449,852. ELECTROMAGNETIC APPARATUS; C. A. Cadwell, Cleveland, Ohio. App. filed Nov. 25, 1916. Device to regulate and control electrodes of welding apparatus.

1,449,861. FURNACE REGULATOR SYSTEM; H. King, Wilkinsburg, Pa. App. filed Dec. 13, 1919. Automatic regulation of electrodes.

1,449,863. TWO-PHASE HIGH-FREQUENCY ELECTRIC ALTERNATING-CURRENT GENERATOR; M. C. A. Latour, London, England. App. filed June 23, 1920. Homopolar alternator for wireless telephony and telegraphy.

(Issued March 27, 1923)

1,449,871. MODULATOR; J. B. Pratt, Schenectady, N. Y. App. filed Jan. 12, 1922. High frequency current magnetic amplifier.

1,449,878. MODULATOR; E. Austin, Schenectady, N. Y. App. filed Jan. 12, 1922. Magnetic modulator to control amplitude of antenna current.

1,449,879. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed April 4, 1919. Main control electromagnet operated by current flowing through furnace.

1,449,880. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed June 25, 1919. Regulator for operating electrode motor in accordance with voltage and current conditions of supply circuit.

1,449,881. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed June 25, 1919. Regulator governs operation of movable electrodes to maintain equal heating effects.

1,449,882. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed June 25, 1919. Automatic regulator prevents hunting section of electrodes.

1,449,883. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Aug. 26, 1919. Automatic regulation of movable electrodes.

1,449,884. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Aug. 26, 1919. Electrode movement controlled by current passing through it.

1,449,885. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Aug. 26, 1919. Two electrically operated switches control electrodes.

1,449,886. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Oct. 2, 1919. Electrode regulator controlled by amount of currents passing through electrode.

1,449,887. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Nov. 13, 1919. Governs operation of movable electrodes.

1,449,888. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Dec. 3, 1919. Two differential windings selectively energized to change setting of main magnet of electrode regulator.

1,449,889. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed Dec. 3, 1919. Electrode regulator comprises a main control having a main and an auxiliary electromagnet and two switches.

1,449,890. FURNACE REGULATOR SYSTEM; C. A. Boddie, Pittsburgh, Pa. App. filed April 14, 1920. Current electrode controlled in accordance with potential across supply circuit.

1,449,896. FURNACE REGULATOR SYSTEM; R. D. Evans, Wilkinsburg, Pa. App. filed Oct. 16, 1918. Separate motor for raising and lowering each movable electrode.

1,449,897. ELECTRIC FURNACE REGULATOR SYSTEM; R. D. Evans, Wilkinsburg, Pa. App. filed April 9, 1919. Automatic control of electrodes.

1,449,898. COIL-WINDING MACHINE; C. Fayer, New York, N. Y. App. filed Jan. 4, 1921. For winding coils used for producing high-tension currents, impulses and discharges such as X-ray machines.

1,449,904. TELEPHONE TRANSPORTATION SWITCHING BOX; E. Love, Prince Rupert, B. C., Canada. App. filed Aug. 22, 1921. For transposing long-distance telephone lines.

1,449,908. ELECTRIC VALVE GRINDER; J. J. McGuckin and John Peyer, Brooklyn, N. Y. App. filed April 2, 1921. For internal-combustion engines.

1,449,911. METHOD AND MEANS OF RECEIVING SIGNALS; R. H. Ranger, Brooklyn, N. Y. App. filed Nov. 12, 1921. Signal recorded by several stations and wave form compared to secure original signal sent out.

1,449,919. NON-INDUCTIVE INTERFERENCE SYSTEM; J. Slepian, Wilkinsburg, Pa. App. filed March 8, 1919. Counteracting any induced voltage by impressing equal and opposite voltage on line.

1,449,970. PLATE HOLDER FOR TAKING RÖNTGEN PHOTOGRAPHS; G. Bucky, Berlin, Germany. App. filed Jan. 20, 1921.

1,449,982. SELF-WINDING CLOCK; J. T. A. Gaucher (deceased), late of Montreal, Que., Canada. App. filed June 26, 1920. Electrically wound.

1,449,984. ALTERNATING CURRENT LOCAL CIRCUITS FOR CODE SIGNALING TELEGRAPHS; J. J. Ghegan, East Orange, N. J. App. filed April 8, 1919.

1,449,985. AUXILIARY DEVICE FOR TELEGRAPH KEYS; J. J. Ghegan, East Orange, N. J. App. filed July 10, 1919. Increased speed in transmitting possible.

1,449,987. STATIC POTENTIAL-CONTROLLING APPARATUS; R. M. Gilson, Pittsburgh, Pa. App. filed June 4, 1919. Series-circuit lamp contact.

1,449,991. METHOD OF AND MEANS FOR COUNTERACTING DESTRUCTIVE ELECTROLYSIS; L. O. Gunderson, Decatur, Ill. App. filed Nov. 4, 1921. Electrolysis in steam boiler neutralized by a secondary cathode.

1,450,002. ELECTRIC CONNECTOR; J. Lofgren and A. R. Ayers, Chicago, Ill. App. filed June 28, 1919. Especially adaptable for use on locomotives.

1,450,004. ELECTRODE ELEMENT FOR GALVANIC BATTERIES AND METHOD OF PRODUCING SAME; M. L. Martus, Woodbury, Conn. App. filed Feb. 8, 1922.

1,450,022. REFLECTING HEAT APPLIANCE; J. E. Doyle, Cleveland, Ohio. App. filed Oct. 15, 1921. Drying printed paper as it passes through press.

1,450,025. SAFETY X-RAY APPARATUS; E. L. Edwards and F. A. Farwell, Indianapolis, Ind. App. filed Nov. 6, 1920. Inclosure for high-tension transformer.

1,450,038. COMBINED WAVE CHANGER AND WAVE METER; G. Hill, Washington D. C. App. filed April 28, 1920. For determining wave length of wireless receiving set at all times.

1,450,043. PRIMARY BATTERY; M. L. Martus, Woodbury, and J. G. Ross and E. H. Becker, Waterbury, Conn. App. filed Oct. 24, 1921. Zinc electrode with annual rib on its outer surface.

1,450,046. SWITCH COVER AND SUPPORT; W. J. Newton, Bridgeport, Conn. App. filed Jan. 13, 1920. For automobile lighting and ignition systems.

1,450,057. TROLLEY SWITCH; A. Zimmerman, Ansted, W. Va. App. filed Jan. 12, 1922. Section insulator.

1,450,059. PRIMARY BATTERY; E. H. Becker, Waterbury, Conn. App. filed Nov. 18, 1921. Indicating apparatus attached to battery shows state of exhaustion.

1,450,061. OPTICAL METHOD FOR PRODUCING PULSATING ELECTRIC CURRENT; W. W. Coblentz, Washington, D. C. App. filed Aug. 6, 1920.

1,450,080. METHOD AND ELECTRIC CIRCUIT ARRANGEMENT FOR NEUTRALIZING CAPACITY COUPLING; L. A. Hazeltine, Hoboken, N. J. App. filed Aug. 7, 1919. Prevents the transmitting of undesirable disturbances from one circuit to another.

1,450,141. SUPPORT FOR ELECTRIC CURRENT COLLECTOR SHOES; E. A. Davis, Harvey, Ill. App. filed April 30, 1921. For traveling cranes.

# The Essence of Public Relations

HERE is a healthful message for all utility executives. It comes from the heart of an American citizen — a householder, a consumer, a customer, one of those buyers of service and securities who regulate and in the last analysis own all public utilities. It is for this man and others like him that public service corporations are operated. He writes:

What better advertising matter could the Chamber of Commerce of Syracuse have than a reprint of the article in the April 14 issue of the *Electrical World* describing the wonderful service rendered by the Syracuse Lighting Company? If any other large lighting companies in this country are giving service that in any way approaches that of the Syracuse company, please print a few more stories about them. Give them your front-page editorial space. They have earned it. Perhaps if a few of these stories appeared some of the other central stations in the country would wake up enough to be ashamed of their methods and would reform.

I was once with one of the largest managing organizations of this country. I know the problem from the inside. And let me say right here that I do not believe that the problem is one bit harder than the sales problems of large non-public utility organizations. My sympathy has always been for the utility, but I confess that it is waning for one utility whose annual output ranks high in your recent list. Here is the way that utility does it:

On rather short notice I found it necessary to change my apartment. I went to the main office of the lighting company to request the change. Before me was a sign telling all comers that the business of the company is service. I waited twenty-five minutes in front of my sign-greeting. This time was not all wasted because I was entertained by the troubles of others. I could hear only the eight directly in front of me. Three of these eight came about new problems. Five had complaints.

When my turn came I was instructed where to sign and told that accedance to my desire to have the service changed in one week was rather doubtful as the company required a ten-day notice and in addition this was its busy season. I was assured, however, that the matter would have the company's best attention. While I waited the locations were looked up, verified, and, as if to cheer me up, I was told that my move was to a new apartment and that a permit for connection had been issued to cover the entire building. My impatience at waiting had subsided, and I went away feeling that the company had a large problem on its hands and that I really might have service in a week instead of ten days.

Moving day arrived. No electric service. A telephone call gave me the information that no permit had been issued. No arguing on my part about the casual remark made at the main office on this subject when I applied for the change was of avail. What was I to do? Oh, I could call the main office and tell them they were all wrong on the permit stuff, or I could get the owner of the apartment to get after the town wire inspector.

I called the town wire inspector myself, and he told me that he would issue a permit any time the lighting company requested it. He had inspected the building but only issued service connection permits when the lighting company requested them for each apartment.

Another call to the lighting company. They agree to connect. When? Tomorrow, perhaps; no connections were made in that town on Tuesdays. Result, I go to the corner store and buy my candles, and forever and a day—try as I will to forget this petty incident—I will just naturally feel that the company cares not for its customers and that I must do my part as a loyal citizen to oppose any rate increases.

Perhaps I had better take an active part in the local movement to require the lighting company to place all of its wires on the main streets underground. No, I am not a grouch by nature, so I am going up to the gas office to smoke a cigar with the manager. He changed my service on the day I wanted it changed and did it all by telephone request. But, then, the gas company only serves a territory of thirty thousand people and the lighting company serves one of over a million. Perhaps that is why the gas company is still a he while the lighting company is they.

PICTURED in this letter we have the very essence of public relations—that thing in which the industry is so absorbed today. It seems a small matter from within — the coming of a stranger to the application window. But these are the contacts of which good will is builded, the elements in service which make the central station and its manager well and favorably known — or not.

# James Berry Foote

*A pioneer in the development of hydro-electric power and transmission and a constructive influence in interurban railway practice.*

THE economical utilization of hydro-electric power has been made possible by high-voltage transmission, and in the development of engineering equipment and methods some remarkable contributions have been made by central-station engineers.

James Berry Foote, pioneer in the development of hydro-electric power and transmission at high voltage in southern Michigan and chief engineer of the Consumers' Power Company, was born at Adrian, Mich., in 1867. His early electrical experiments were made in Adrian, and he started the plant that furnished the first electric light in that community. He went to Jackson in 1886, where in company with his elder brother, W. A. Foote, he initiated the first comprehensive street-lighting system, one which later developed into the present system of the Consumera' Power Company.

It is in the development of high-potential transmission lines and equipment that Mr. Foote's most important engineering work has been carried out. In 1898 he designed and built the transmission line, 25 miles in length and operated at 25,000 volts, from the Trowbridge, Otsego and Plainwell plants on the Kalamazoo River to Kalamazoo. Between 1900 and 1902 he raised the voltage of this line to 40,000 and extended it to Jackson, a total distance of 93 miles. In 1905 the transmission line from Rogers Dam, on the Muskegon River, to Grand Rapids, 55 miles long, was built and placed in service at 72,000 volts. So far as is known this was the highest transmission voltage in use in the world at that time.

In 1906 the Croton-Grand Rapids line was built and placed in service and operated at 110,000 volts. This line, 43 miles in length, was one of the earliest to use the steel tower and suspension-type insulator. The 140,000-volt transmission line from the Au Sable River generating plants to Saginaw, Flint and Owosso was designed by Mr. Foote and placed in service without revision in 1911. This line was originally 151 miles long, on steel towers, with suspension insulators, and was the highest-voltage transmission line in the world for several years.

The 140,000-volt line now extends from Mio, on the Au Sable River, to Battle Creek and Jackson, a total distance of 343 miles. With the 175-mile line from the Manistee River to Kalamazoo and Battle Creek, the Consumers' Power Company now has a total of 517 miles of 140,000-volt lines in operation. By Mr. Foote's constructive leadership in transmission-line design the distance of economical transmission of power has been increased to over 300 miles.

### Relative Effectiveness of Direct and Indirect Illumination

NO SUBJECT connected with illumination has been the cause of more controversy than the relative merits of direct and indirect lighting. The quarrel has not been merely a commercial one such as might be reasonably expected, but a technical one also, and in that aspect there is less reason for variations of opinion. A number of so-called practical studies have been made dealing with the properties of light falling directly on the page and falling upon it after reflection from the walls and ceiling, and utterly diverse data have been obtained. The probable cause of these striking discrepancies is the fact that any investigation of this sort tends to emphasize psychological rather than physical values, values therefore determinable only in vague impressions of comfort and discomfort, of ease and difficulty, of fatigue and facility.

In any tests made upon the eye other factors than the ordinary ones of shade perception and acuity of necessity enter. The particular kind of work attempted, the extent to which the several illuminations are pushed above the limit for moderate acuity, the contrast of the things observed and the length of time for which the observations may be continued, all are things which enter the final judgment as to the sufficiency of the illumination received. There is added to these causes of uncertainty a still greater one in the element of unconscious suggestion in the manner of the test or the instructions given for carrying it out. It would not be difficult to make a given group dissatisfied with almost any system of illuminaion without an expressed word of disapprobation. As a matter of fact there can be no sweeping decision between direct and indirect lighting. Some of the worst and some of the best examples of illumination alike belong to each.

### Rivalry Between Electrical Men's Own Home Equipment Good for Us All

IT IS generally agreed that the electrical man himself has been about the hardest "prospect" to interest in the use of electrical appliances in his own home. Theoretically he has believed in them from the beginning, but he has thought about them and supported them mainly during business hours. He has not tried very hard to "sell" his wife on the daily use of electricity for saving labor, and the electrical equipment of the electrical man's home has never been a beacon to the community. The action of the New York Electrical League in holding a contest among its members to determine whose house is the most completely electrified is, therefore, worthy of attention. It offers a basis for developing interest and rivalry between the men and women of any electrical group or within any electrical organization that is bound to stimulate acceptance of the responsibility which all electrical people should feel to set an example to the public in the enjoyment of and dependence upon the good things which electric service offers in the home today.

The idea was born on the special car that carried the delegates west to the N. E. L. A. Commercial Section meetings in Denver some months ago, and the "Electrify Club" was formed as an informal organization to promote contests among electrical men and bring publicity to those whose homes are well equipped. Prizes are awarded by rating houses on a point system, crediting each type of outlet and appliance, and the plan offers a spectacular demonstration of the degree to which comfort and convenience can be introduced into the modern home—electrically. Here is an idea that can profitably be furthered by the central-station company in every community.

### Noted Electrical Engineer and Motor Manufacturer Passes Away

SCHUYLER S. WHEELER, who died last week, was one of the pioneer electrical engineers of the country and throughout his entire professional life lent distinction and adornment to the profession. All that he undertook was performed with precision and thoroughness, and once convinced of the accuracy and justice of an opinion he clung to it tenaciously and fought for it with determination. Dr. Wheeler was one of those rare men who combine the knowledge and thoroughness of the engineer with the skill and executive ability of a captain of industry. Moreover, he always commanded the highest admiration because of the ethical standards on which his entire career was built.

Starting originally in the electric light and power field he engaged soon afterward in the field of electrical manufacture and was among the first in the country to recognize the necessity of a standard line of high-grade small electric motors. Owing to his accurate mechanical perceptions and creative ability, the products of his company received from the outset widespread recognition for superiority of design and efficiency. Among the outstanding electrical contributions of Dr. Wheeler to our modern civilization was the electric fan.

Professionally Dr. Wheeler always stood high. He served a term as president of the American Institute of Electrical Engineers and was the author of an engineering code of ethics which commended itself to professional men throughout the world. His keen interest in the electrical engineering profession and its traditions is evidenced by his presentation of the most complete and rare collection of electrical books in the world, the Latimer Clark library, to the American Institute of Electrical Engineers, and also by his choice of the name Ampere for the delightful industrial and residential community surrounding the works of the Crocker-Wheeler Company in New Jersey. To house the Latimer Clark libary was one of the objects which moved Andrew Carnegie to provide the funds for the Engineering Society Building in New York City.

In his dealings with men and corporations Dr. Wheeler

was absolutely fearless. He rid New York City of the labyrinth of overhead wires in the late eighties when he was expert of the Board of Electrical Control, and the utilities which then fought him have since come to honor and respect him for his fairness and the real protection which arose from his action at that time and have since surrounded the telegraph, telephone, electric and railway services of the city.

Although outwardly somewhat brusque and austere, inwardly Dr. Wheeler was a man of warm human sympathies and affections, as shown in the way he helped the maimed and blind to maintain their self-respect and to be self-supporting. His death robs the profession of one of its most verile and picturesque characters.

### Return to Private Ownership in Europe

CLOSE observation of conditions in Europe revealed hopeful signs to members of the United States Chamber of Commerce who recently went over there for that purpose. The information and the opinions presented by their spokesman, Julius H. Barnes, ought to be valuable to American business men in that they stimulate optimism and indicate that a normal Europe is within the range of vision. If ever we are to get a proper perspective of Old War conditions, it must be through American eyes. Italy Mr. Barnes considers to be "the most promising country of those in the war." Since the communistic control of industry has been destroyed by the popular Mussolini, manufacture has greatly increased. Poor Austria, the Chamber of Commerce observers find, is traveling an apparently safe road to early rehabilitation. British trade is expanding, and even in Russia commercial conditions are growing better.

Mr. Barnes recognizes as "the outstanding fact" in European conditions the tendency to get away from state ownership and operation of what he calls public facilities. "Not only," he says, "is this shown in Italy's effort to get all its public state-owned facilities in private hands, but it is shown in Austria, where there is a recasting of the government railroad service and a discharge of a hundred thousand superfluous employees. It is shown in Great Britain, where the railroads under their return to private operation have greatly quickened the business and economic life of that island and greatly improved the service and at the same time reduced the rates. It shows there is a general appreciation throughout all of Europe that these facilities must not only be in private hands, but they must be regulated so wisely that they will present a field of attraction for the superior grade of private ability to enlist itself in their administration, and that it is true that where this has been tried, as in Great Britain, they are meeting with satisfactory results."

These unofficial American observers see in all this a strong and compelling argument for the further development of public facilities in this country under private ownership but with an intelligent measure of government supervision. Facts like these ought to be brought home to every citizen at this time, when private ownership is being attacked and commission regulation scoffed at. Adversity and distress have revealed to Europe the shortcomings and fallacies of government ownership and the necessity of the stimulating and driving force inherent in private ownership. Like us, Europeans recognize that public service monopolies require regulation—a little more constructive perhaps than that experienced by the railroads—and they are preparing to follow in our footsteps, which may be regarded as a wonderful indorsement.

### A Family Triangle

OPERATING companies need trained men for subordinate positions, and also better educated professional men for positions of administrative responsibility and for those requiring advanced technical skill. It is the purpose of the trade schools to furnish training of the first kind, and it is one of the functions of high-grade universities and technical institutes of similar rank to provide men who can advance to higher positions. In this respect the two kinds of schools and the operating companies form a harmonious three-cornered family. This relationship is clearly and convincingly expounded in M. S. Sloan's article, published elsewhere in this issue, and every statement in it should be read with interest both by operating men and by teachers.

It seems much easier to establish a close relationship between the operating companies and the trade schools than between the operating companies and universities. In other words, in the family triangle the vertex which represents the institutions of higher learning seems to be quite remote from the other two vertices. Mr. Sloan desires to make the triangle more nearly equilateral through the activities of the N. E. L. A. committee on co-operation with educational institutions. This work properly conducted should prove of great benefit to all concerned.

It is refreshing to read Mr. Sloan's plea for less quantity and more quality in university training—for a training in reasoning, in observation, in service and in life problems, rather than in specific details of the electric light and power industry. This should be encouraging to faculty committees on courses, which oftentimes spend weary hours arguing how to put five gallons of information into four-gallon heads.

### The Radio Telephone in Transmission-Line Service

IN THE very interesting experiments on communication over transmission systems with the so-called "wired wireless" as a substitute for ordinary telephony, commented on recently in the ELECTRICAL WORLD, some of the weak as well as the strong points of the system have been brought to the front, the chief difficulty being that inasmuch as radio in this sense is dependent on the transmission lines and these are the usual seat of serious trouble, the power service is in an emergency very likely to take the radio service out of duty with it. Ordinarily radio transmission is at least free from entangling complications due to the power wires, but, as thousands of readers well know, it is now and then afflicted with troubles of its own. The broad question regarding the usefulness of radio on the transmission system simply resolves itself into this: Can radio distribution with a moderate amount of energy and conveniently practicable apparatus be relied upon to transmit intelligence over a radius of a hundred or two hundred miles under substantially all conditions?

It is a gratification to put on record the experience of the San Joaquin Light & Power Corporation in patiently thrashing out a solution. The full description of the sending set will well repay careful reading as it

represents the result of a great deal of experience. The main thing is that the whole set was built up of standard parts and at a total cost of only about $750, and that, working initially on a four-wire antenna 75 ft. high and 175 ft. long with a counterpoise of the same size, the sending set actually radiated 4 amp. at 360 meters wave length. When used as a broadcasting station to test its capacity, it worked clearly to stations on the Atlantic Coast more than 2,500 miles distant, and within the small radius over which it is necessary to work in transmission service there was remarkably good and regular reception everywhere. Reports even from the more distant stations showed that the volume was good and the modulation excellent. Of course, to duplicate such a system between important stations one has to adopt the usual expedient of sending at one frequency and receiving at another, the latter being the sending frequency for the duplex station and the former its receiving frequency.

It looks as if the San Joaquin experiments had reached a thoroughly practical result and had established the right of a well-planned radio system to be considered reliable. Just what difficulties may be met at times remains yet to be seen, but the results are highly encouraging. On a radio system of any kind there is not the facility for cutting in and talking back with which an ordinary telephone line is endowed, but whether in the direct-wave or free-wave form radio seems capable of fulfilling a very useful purpose in dealing with networks too large to be intrusted solely to ordinary telephony.

## New Ideas Needed on Circuit-Breaker Construction

REMARKABLE increases in the rupturing capacity of oil circuit breakers have been gained in the last few years through various improvements. However, the majority of increases in rupturing capacity have been made by increasing the dimensions or speeds of operation of the circuit breakers. As H. A. Barre, electrical engineer of the Southern California Edison Company, once expressed it, the present high-voltage circuit breakers are composed essentially of a Standard Oil tank with a wagon tongue carrying the movable contacts. The disadvantages of increasing ratings by increasing dimensions are so obvious that the engineering talent of this country should be stimulated to devise a means of performing the same results in another manner.

Just with the idea of promoting thought on the subject, it is perhaps worth while to cite one scheme proposed which, while it may not be itself the solution, may suggest other means of attacking the problem. The proposal is to build the tank for supervoltage circuit breakers below the ground level and to build it of concrete lined with sheet metal welded at the joints. There would be no stationary contacts. Each pair would be moved in a horizontal plane by a grasshopper motion. Existing improvements in circuit breakers could be made part of the plan. The results sought by this construction would be the elimination of transportation difficulties, an increase in separation of contacts, the rupturing of the arc in a position which would facilitate its extinguishment, the reduction of oil fire hazard, and possibly the reduction of oil required.

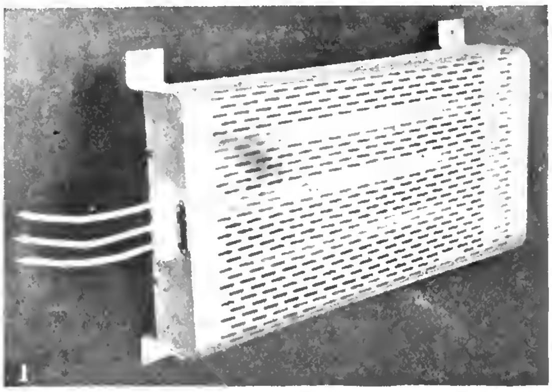
Reduction of high-potential bushings has been proposed by combining the transformers, disconnecting switches and circuit breakers in similar underground tanks separated by barriers and sealed with manhole covers. These proposals, while sounding like some of the tales of Jules Verne, will be of value if they do no more than stimulate new ideas on the construction of high-potential apparatus.

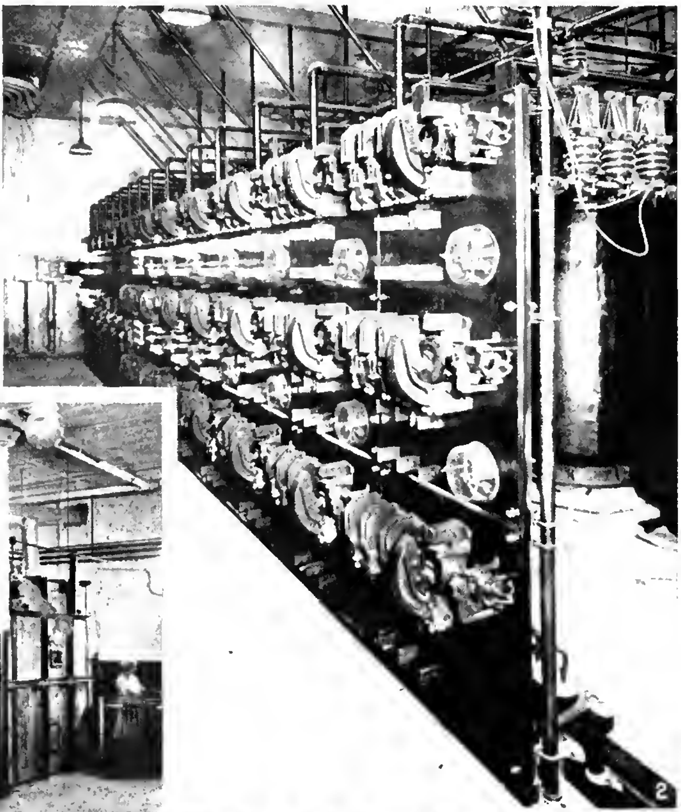
## Wider Vision Required in Regulation

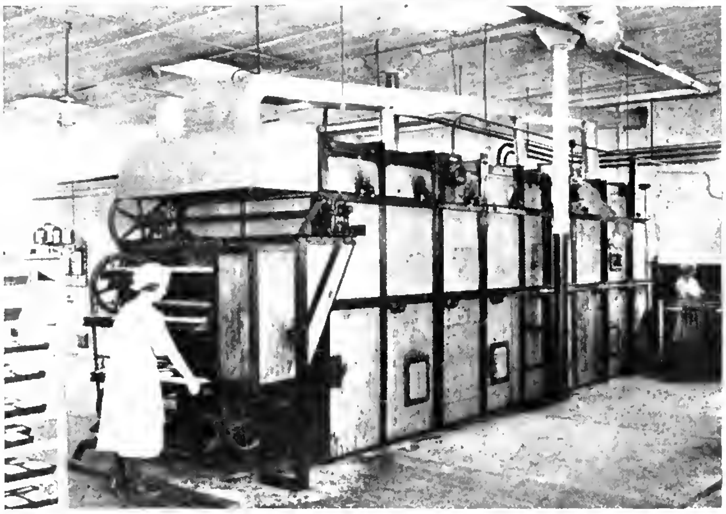
FROM time immemorial the desire for gain, whether of territory, prestige, position, fame or money, has been the impelling motive that has urged nations, communities, companies and individuals onward. Robbed of that incentive they either stand still or go backward and their contribution to society becomes nothing or less than nothing. Who cares to labor if the only compensation is a wage fixed and never increasing? Ditch diggers we must have, but even a ditch digger longs for the time when he can lay his pick and shovel by for some task less trying on his back and more remunerative in its return. To that end he does his appointed task well and fits himself for something better, and what is true of the humblest individual is true of a group or of a nation. Ambition is a natural trait, and reward usually crowns the effort of the one who succeeds at his task.

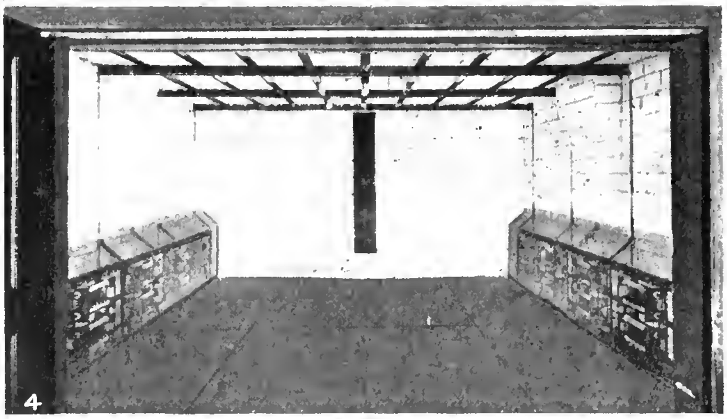
It is unfortunate that the trend of modern regulation does not take proper cognizance of this human instinct. In the desire to fix rates which are just and reasonable very little thought is given to incentives which might result in improved service. There is no fault to be found with the law; the trouble lies in its application. Courts generally recognize that the power to regulate is not a power to destroy and that limitation is not the equivalent of confiscation. But commissions are usually so engrossed and occupied on cases of the present that they have little time for consideration of the broader application of these principles and their effect in the future. Thus, whether a company exercises initiative and enterprise in the development of its territory and shows extraordinary skill and efficiency in the operation of its system or whether it does not apparently matters little. All that it is allowed is a fixed return on the investment. No distinction is made between sheep and goats. If a well-managed company, because of the exercise of extraordinary skill, succeeds in earning more than its allotted return, the surplus is virtually confiscated by the state through reduction in rates. Thus a check is placed on ambition and the exercise of initiative and enterprise is discouraged rather than encouraged. Fortunately, the electric light and power industry still takes pride in keeping its rates as low as possible, and because of higher costs of labor and material this has necessitated greater improvements in efficiency of equipment and in operation, the fruits of which have been passed on to the public. This process cannot continue indefinitely, however, and unless some reward is offered for efficiency great effort will scarcely continue to be made to attain it. The electric light and power business requires an uncommon degree of skill and experience in its conduct. It is still subject to risks, and industry, rather than make the venture itself, looks to the electric public utilities for service. Every encouragement should be given to them to expand and grow, to attract brains and capital and to help develop and perfect an art and science so universally serviceable to the race.

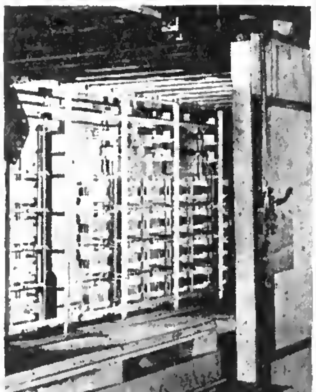
# Typical Electric Heat Applications











No. 1—An industrial air heater containing four 500-watt steel-clad heaters. An aluminum reflector is mounted in the rear.

No. 2—Automatic-control panels for maintaining constant temperature in an enameling oven at the Cadillac Motor Company's Detroit plant.

No. 3—A continuous-conveyor sectional type of bread-baking oven can produce more than 1,200 loaves per hour.

No. 4—A truck-type enameling oven for doors and cornice work.

Nos. 5 and 6—A semi-continuous conveyor type enameling oven at the plant of the Packard Motor Company, Detroit. At the left the fenders are shown, at right the resistors.

No. 7—A core-baking oven operates at around 400 deg. to 450 deg. F.

# To Paint or Galvanize Steel Structures?

## Results of a Questionnaire on This Debated Subject Give No Conclusive Answer—Proofs Are Not Forthcoming and Definite Data Are Few, but Positive Opinions Are Expressed by Some

In an attempt to answer the many questions asked about the relative merits of painting and galvanizing outdoor steel structures a questionnaire was sent to operating companies and consulting engineers. The accompanying analysis of the replies and the definite material presented should prove of value, but all the evidence shows that definite steps should be taken to obtain more accurate cost and performance data. Operating companies have kept very insufficient records on this subject, which has become increasingly important.—*Editors.*

OUTDOOR steel structures are widely used in the electrical industry, but they have been adopted so rapidly that despite this widespread employment few field data have been available on which to determine the relative merits of galvanized and painted structures of the various kinds. The experience of other industries helps little because of the distinctly different construction and application features of the structures used for electrical purposes.

For transmission-line towers and for substation structures the fabricated steel must be light and of many parts, and it must be economical as regards first cost and maintenance cost. Bridge practice and the general application of sheet steel give few data of a type which can be applied to these electrical structures, and there has been little real engineering study devoted to them by electrical engineers.

A survey of this matter in the electrical industry has brought out facts that show the existence of fields for both galvanized and painted structures. Many positive opinions have been elicited, as well as a few accurate data on installation costs, maintenance costs and length of life of the protective coating.

### Advantages and Disadvantages Summarized

A summary of the advantages of the galvanized structure may be thus given:

1. Where parts of the structure are not readily accessible or dangerous to life—for example, near live wires—galvanizing has advantages.

2. Where the structures are widely scattered and the cost of a careful inspection would be heavy, galvanizing is also advantageous.

3. Where a permanent installation of sufficient magnitude to warrant a company doing its own galvanizing is made, the cost of galvanizing adds only 20 to 30 per cent to the cost of the steel.

4. In fabricated structures where bolts are used galvanized parts have a longer life.

5. In some structures it is possible to use lighter steel if it is galvanized than if paint is used. For example, one company reports that galvanizing increases the cost about a third, but permits the use of ¼-in. angles as compared with the $\frac{5}{16}$-in. angles required for painted structures.

6. The length of life of the galvanizing is from eight to fifteen years as compared with two to four years for paint.

The disadvantages of galvanized structures are:

1. First cost is high—reports give figures varying from 30 per cent greater to nine times the cost of painting.

2. The quality of galvanizing varies, necessitating rigid specifications.

3. In certain locations—for example, in a damp, salty atmosphere and in a sulphur-laden atmosphere—galvanizing has a very short life, so that its application is somewhat limited.

The advocates of painted structures are rather numerous, particularly where certain types of structures are concerned. Certain of the advantages of painting are:

1. It is cheaper than galvanizing, and this makes it particularly advantageous for new installations in which the capital charge must be kept low until the load grows.

2. It costs little to have painting done by the normal line crew during odd moments.

3. Paint of different qualities can be found suited to peculiarities of the location of each structure as regards weather conditions, air conditions and a changeable environment.

On the other hand, paint has some disadvantages, for:

1. It is difficult to obtain paint of the proper quality for each application.

2. Two or more kinds of paint must be used to obtain good results.

3. Repainting must occur in from two to four years, and in many cases this is a very costly operation, particularly if structures are brushed or scraped before repainting.

4. Repainting of live structures is hazardous and it is difficult to "kill" substations or lines.

Several companies state that their practice is to use both galvanized and painted structures. For tower lines galvanizing is generally preferred, but under special conditions painted towers are used and very frequently the bus structures, arrester tanks and breaker tanks are painted. Nearly all say that the quality of the galvanizing and of the paint is very important. A wide variety of choice in paints is found, with a red-lead base and aluminum top coat in general favor.

### Variation in Costs

One company reports the cost of painting a steel-tower line installed in 1916 as $8.95 for labor and $1.42 for paint per tower, or about $1.50 and 24 cents per tower-year respectively. Another company gives the cost of painting as ½ cent per pound of steel painted, while the cost of galvanizing is 1 cent a pound or higher, depending on the tonnage of the order.

It is rather difficult to make positive deductions from reading the various answers, but a consensus of opinion exists to the effect that galvanizing can be used advantageously for transmission-line structures and isolated substation structures where these are just outside of

more or less thickly populated sections. Galvanizing also has advantages over painting for parts of switching structures which are rather inaccessible because of the proximity of live parts which cannot be "killed." If such structures are exposed to acids or fumes, extra-heavy galvanizing should be specified and paint put on the galvanizing after it has weathered better to protect it from fumes.

For all other structures painting seems to be as satisfactory a method for protecting steel as can be obtained, provided that a first-class paint is selected, suited to the purpose for which it is used, and that at least three coats of the paint are properly applied. Skilled painters should do the work if a good job is to be obtained.

In order to report the conditions ascertained more definitely a selected list of companies and the statements made by their representatives are given below. It is hoped that a more thorough investigation of the subject will be undertaken by the industry and that field records will be kept by companies located in widely scattered locations.

## Opinions from Users of Outdoor Steel

### Connecticut Light & Power Company

Waterbury, Conn.

We have not made any extensive tests to determine the relative final cost of galvanizing versus painting. We have used different kinds of paints for some years and have come to some very definite conclusions as to the value of different paints under different conditions.

As far as galvanizing is concerned, it is our general policy to galvanize all such parts of steel structures as after erection are not readily accessible on account of their close proximity to live parts of conductors and equipment. This refers to steel used in outdoor substation work. On line towers and other steel structures we are using, wherever possible, galvanized iron, because part of the structure is not readily accessible for painting on account of proximity to live parts, and because on the whole the structures are scattered so far that a painting job would be expensive. Moreover, the close supervision necessary to determine when painting is required would add materially to the cost of inspecting the line. Of course, there is always a chance of rust, even with galvanizing. However, rusting does not progress very rapidly, and very infrequent inspections will be sufficient to discover it and to permit taking the necessary steps to arrest it.

As far as the painting is concerned, we first used a red lead and various paints on top of it as a second and third coat, some dark green and others battleship gray. We even tried some of the heavy black compound paints in an endeavor to obtain a paint that would last some time. As a rule we found that we could not let painting go more than three years at the most without considerable rusting taking place. This refers particularly to Waterbury, where the conditions may, of course, be more severe on account of the close proximity of a spray cooling system. We accidentally started to use the paint which is now our standard, namely, the aluminum paint. We first used it in New Britain, where we were installing the first outdoor station, using galvanized trusses, but painting posts so that a post should as nearly as possible look like the truss—therefore the aluminum paint.

We first mixed this aluminum paint with banana oil. The experience was most discouraging, because the paint was flaky and did not last very long. After considerable experimenting we were finally advised by a paint manufacturer to use the following mixture: 1 lb. of powder aluminum paint to 2 qt. of Sipes "bronze liquid." Ever since we have done this the results have been most encouraging. As a matter of fact, they have been so encouraging that we have standardized on the aluminum paint not only for the steel structures but also for the circuit-breaker tanks, lightning-arrester tanks and rain shields (O. F. arresters) and power transformer tanks.

It was about three years ago that we started to use the new mixture for the aluminum paint, and the parts painted since do not show any signs yet of needing repainting. Just how long we can go without repainting I am unable to tell at this time. E. J. AMBERG,

*Electrical Engineer.*

### Cumberland County Power & Light Company

Portland, Me.

All our outdoor steel structures are painted. Our Hiram transmission line, approximately 15 miles long, is a tower line of A frames and rigid towers. This was placed in service in 1916 and was painted this year at a cost of $8.95 per tower. The original paint was so-called "Carbon Elastic." This year we used "Valdura," which is practically all "Gilsonite." The price of $8.95 is for labor only and this represents a cost of about $1.50 per tower per year. The cost of the material used amounted to $1.42 per tower, or at the rate of about 24 cents per tower per year.

GEORGE E. HAGGAS,

*Chief Engineer.*

### Public Service Production Company

Newark, N. J.

All our outdoor steel structures are painted. We have used no galvanized structures to date. We have no data as to the average life of protective coating, but our practice is to use the best grade of paint and repaint structures about every two years. As to kinds of paint, we have had satisfactory results using Patton's "Iron Hide," Suydam's "Dock Department" paint and "De-re-ko."

We have no data showing the cost of painting based on the life of protective covering. Our climatic conditions are bad on account of salt air and acid fumes. We do not believe that galvanizing would provide a complete protection unless members were double galvanized. Even in this case, structures would have to be painted after 5 or 6 years use. E. B. MEYER,

*Chief Engineer.*

### Niagara, Lockport & Ontario Power Company

Buffalo

I am sorry that I cannot give you any exact dollars-and-cents figures which will support our decision in favor of painted instead of galvanized transmission structures for our recent order, but I can state some of the general considerations which have led to this policy at the present time.

We installed in 1905-1906 more than a thousand towers of each type. The painted towers have been repainted approximately every four years. Some of the galvanized towers erected near the industrial centers or near railroad right-of-way, where they are exposed to gases and smoke, showed serious impairment of the galvanized protection after seven years of service, although others, erected in the open country, are still in fairly good condition. I believe, however, that I can conservatively state that all structures in the vicinity of railroad right-of-way and in the outskirts of settled communities were badly in need of repainting after ten years of service. For such towers, therefore, the saving effected by galvanized structures is roughly represented by the cost of two and one-half repainting jobs. In computing the cost of such repainting jobs a very substantial credit should be made on the cost of labor, because this work can be done by the regular line organization at odd times when there is no need for their services on other maintenance or emergency work. It should also be considered that the first painting job on a galvanized tower after rusting has started in is considerably more than the repainting of a well-painted structure. We have also found that there is a good deal of difference in the durability of different galvanized structures, sometimes from the same firm but manufactured at a different date. Such difference could possibly be avoided by more rigid inspection, but a rigid inspection of the galvanizing of all tower parts is necessarily very expensive and would add materially to the cost of galvanized structures. It is, therefore, our judgment that for our lines in western New York, which parallel and frequently

run adjacent to railroad rights-of-way and through the outskirts of several industrial communities, the painted structure is better adapted; but if we had to build a line in open country, free from gases and fumes, we should probably favor galvanized construction.

It also should be considered that the expense of a transmission company is necessarily represented to a very large extent by fixed charges on investment, which cannot be adjusted to changes in earnings, whereas maintenance can always be somewhat synchronized with the earning situation, increased in good times and curtailed when earnings fall off. In spite of the fact that fixed charges on the additional cost of galvanized structures may be less than the average cost of repainting structures during the first ten or fifteen years, it may be better policy to keep down the initial investment for the reasons stated before and also because in most cases it is not possible to show a profitable return from the initial business reached by any new extension, whereas the future growth of this business is usually sufficient to earn eventually a profitable return and increased maintenance charges. I am not sure whether at the present time this relation still obtains, but not so long ago we found that increasing the thickness of all parts of a transmission structure by ⅛ in. did cost less than the galvanizing of the lesser thickness of metal. This, of course, raises the question whether ⅛-in additional metal is not a better protection than the thin galvanized coating. S. PIEK,
*General Manager.*

**East Massachusetts Electric Company**
Salem, Mass.

We use only painted outdoor steel structures and get an average life of about two years for the protective coating. We have no definite cost figures, but we repaint every two years with graphite paint. H. G. JENKS,
*General Superintendent.*

**Narragansett Electric Lighting Company**
Providence

We have but few steel structures, but those we have are not galvanized and, owing to the fact that they are built near the salt water where dampness and frequent fogs prevail, it is essential that they be covered each year with a protective paint.
W. T. OVIATT,
*General Superintendent.*

**Central Maine Power Company**
Augusta, Me.

Our outdoor steel structures are painted, the average life of the paint being three years. We have had no experience with galvanized-steel structures. No data are available for the cost of painting. We have very few of these structures and so have not gone very carefully into the cost of maintenance and upkeep of the same.
GEORGE S. WILLIAMS,
*General Superintendent.*

**Indianapolis Light & Heat Company**
Indianapolis

We have just recently started high-tension outdoor substation construction. Most of our substations are made from 2-in. galvanized pipe and fittings. We have some painted structures also made from Bates steel poles. I have no exact data on the length of time either method will last, but I will say that neither seems to hold up very well for us. The painted structures should really be painted every two years.

We seem to have more trouble with galvanizing on the bolts than we do on the pipe itself. We have several small home-made fittings installed on these stations which were dipped in red lead and then painted with aluminum paint. I do not know just what the cost of this would be if it were done on a large scale, but I am sure it will last twice as long as ordinary galvanizing, judging from our experience in the past two or three years. E. G. RALSTON,
*Chief Electrical Engineer.*

**Northern States Power Company**
Minneapolis

We have on our system several hundred miles of high-tension steel tower or pole-line construction, also innumerable steel-skeleton frame outdoor substations, special switching towers and heavy long-span river and valley crossing towers.

On many of these, erected some time ago, we were unable to obtain galvanizing, as the manufacturers did not have tanks long enough to take the larger members. Of late years, however, many large hot-galvanizing plants have been installed. (One which I know of can take an entire 35-ft. expanded pole section in one dip.) It is therefore now relatively easy to get hot-galvanized outdoor steel members of almost any size.

Hot galvanizing can be regarded as a permanent investment. Our experience has shown that in our climate, remote from salt air, it will last almost indefinitely. The approximate added cost for such galvanizing runs from 15 to 20 per cent of total cost, so that the fixed charges on this extra investment can be balanced against cost of periodic painting. On this basis of comparison galvanizing will nearly always win out on a dollars-and-cents basis.

On outdoor electrical structures in general the electrical equipment must be kept alive at all times. This means painting around live equipment and wires and requires a skilled electrical worker with a knowledge of painting methods—a combination not always easy to find.

Where painting is used for protective purposes it must be carefully watched and repainted before rust sets in. On one of our long transmission lines we were forced by war-time conditions to miss one periodic repainting schedule. When we finally got around to the work we had to scratch-brush every tower, and the repainting cost probably exceeded what would have been paid for hot galvanizing could it have been obtained when these towers were fabricated.

The selection of suitable paint is a problem too deep for the average central-station engineer and further complicated by the fact that a really good paint may give poor service if improperly applied. Most of us fall back on the old rule for selecting a strictly fresh egg—break it open and judge by the smell. In other words, if the paint used gives long service, it is good, otherwise not. In either event we have spent our money to find out.

Our chemical laboratory has recently made exhaustive tests and experiments on paints for various classes of service, and we now have standard paints made to our own special formulas. Even with these we never paint outdoor steel if it is practicable to get it galvanized. On all outdoor hardware and standard fittings, including substation frames, standard towers, etc., we have a standing rule that the workman must not take them out of the storeroom unless they are galvanized, except where order specifically calls for ungalvanized stock. S. B. HOOD,
*Superintendent of Distribution.*

**Public Service Company of Northern Illinois**
Chicago

We have very little definite information on this matter, but consider galvanizing to be more satisfactory than paint. We have a few galvanized towers which have been in service for about ten years without painting and which are just beginning to show signs of slight rust. We have several outdoor steel substation structures which were painted. The paint on them does not seem to stand up for more than about two years. D. A. PIERCE,
*Engineer of Electrical Distribution.*

**Twin State Gas & Electric Company**
Boston

We specify galvanized steel for outdoor substations. Our operations have not to date given us any definite idea as to the probable average life or definite cost data.

Our climatic conditions are rather severe. In one of our localities structures are exposed to some spray from salt water. Galvanizing is in accordance with standard galvanized specifications. Bolt holes are drilled and tapped before galvanizing.
R. J. ANDRUS.

**Scofield Engineering Company**
Philadelphia

Regarding the merits of galvanizing and painting for the protection of outdoor steel structures, we believe there is no question that under most conditions galvanizing is very much more effective.

The average life of protective coating naturally varies widely, depending on the coating and the conditions. For instance, we have had cases where galvanized corrugated sheets have been in position for twenty years without any

apparent deterioration and other cases where such sheets have deteriorated to a point necessitating renewal in ten years or even much less.

Painting of steel structures is ordinarily required every two or three years, and there are some conditions where painting yearly is necessary to secure any adequate protection.

As a general rule, we should say that galvanizing was cheaper than painting in the long run for thin sheets and shapes where any serious damage to the metal requires immediate replacement, and that painting is probably cheaper on heavier structures where a slight amount of corrosion under painting does not seriously endanger the structure.

F. DAUGHERTY,
*Vice-President.*

---

**Wisconsin River Power Company**
Madison, Wis.

We use both galvanized and painted outdoor structures. We have galvanized structures in good shape after twelve years; paint lasts about four years. During the war the cost of galvanizing was high, but now it is cheaper to buy galvanized steel. Our temperature ranges from — 30 deg. F. to + 98 deg. F. with a rainfall of about 30 in.

G. C. NEFF,
*General Superintendent.*

---

**Pennsylvania Power & Light Company**
Allentown, Pa.

We use both galvanizing and painting material on outdoor steel structures. On transmission towers and switching towers we standardize on galvanized material.

Galvanized transmission towers and switching structures have shown no depreciation in ten years except in isolated cases. Painted structures have had to be repainted in from one to five years, according to local conditions.

No comparative data can be given as to the cost of galvanizing or painting based on the life of protective covering, as this varies very greatly on painted structures, while on the galvanized structures there has been practically no deterioration. We have had one galvanized transmission tower out of approximately a thousand which has shown deterioration due to heavy sulphur conditions. Several galvanized towers in culm banks have also rusted at the ground line and have had to be concreted. These are unusual sulphur conditions, however, and isolated cases exist among both painted and galvanized structures of excessive deterioration. However, in ten years there has been no deterioration in galvanized structures where the galvanizing has been satisfactorily done.

The following data give an idea of operating conditions:

Average rainfall, 45 in.; snow and sleet during winter months; heavy lightning storms in summer; temperature range, — 15 deg. + 90 deg.

Frequency of painting is dependent on local conditions and quality of original painting. Normally, steel structures have to be repainted in about three years. Where painting has started to scale and rust it is wire-brushed and red lead or red oxide paint is first used. A carbon paint is used for the finishing coat. Galvanizing is done according to N.E.L.A. specifications or those of the Electric Bond & Share Company of New York.

A special condition affecting the life of galvanizing is the presence of sulphur fumes from coal. This has affected structures where conditions have been very extreme and steel surrounded by heavy coal smoke. In coal-culm piles at the ground line galvanizing has deteriorated. In regard to painting, the quality of the original preparation of the steel, the manner of applying the paint and weather conditions at the time of painting very materially affect its life.

ALEXANDER COLT,
*Superintendent of Transmission.*

---

**Southern California Edison Company**
Los Angeles, Cal.

All of our steel structures, such as transmission-line towers, steel framework for outdoor substations, latticed steel poles and work of that type, are galvanized and not painted. It is hard to tell what the average life of this galvanizing is. We have some structures that have been in use for twenty years that are still in good condition. We have found, however, that in certain localities where the galvanized steel is buried in alkaline soil the galvanizing is being attacked and the steel will clearly have to be replaced. This condition has been noted on the Big Creek line, which is now seven or eight years old; I believe in some instances the galvanizing has disappeared, although the steel has not yet been attacked very badly.

We have constructed many buildings of galvanized corrugated iron, and find it is best to paint this galvanizing after it has been weathered for a few months. The galvanized sheet iron that is purchased in the open market is of rather poor quality and does not seem to be equal to the heavier galvanized sections that are used in steel towers, etc.

H. L. DOOLITTLE,
*Assistant Construction Engineer.*

---

**San Joaquin Light & Power Corporation**
Fresno, Cal.

The question of galvanizing has received considerable consideration from us. Galvanizing is sometimes a large item of expense, and it can be carried to extremes. For instance, material which is satisfactory in a climate such as exists in the central portion of the state would be very unsatisfactory in sections subjected to a great deal of dampness and sea fogs, etc. Material used in the San Joaquin Valley would not stand up when exposed to atmospheric conditions such as exist in the counties on the coast.

All towers which we have purchased, whether for use in the valley or on the coast, are galvanized. Towers such as are used in substation yards to carry high-tension buses are painted. We find that it becomes necessary to repaint these towers about every three years. The galvanizing, if properly applied, will last much longer than that. The cost of galvanizing adds about 15 to 20 per cent to the original cost of the metal.

In the San Joaquin Valley we do not use any galvanized pole-line hardware with the exception of the hooks and eyes, etc., which are used with suspension-type insulators. Our cross-arm braces, bolts, etc., are plain black iron. This climate is very dry, while in Santa Barbara, San Luis Obispo and Monterey Counties the climate is much damper. In these counties we use galvanized hardware throughout.

Our specifications on sheets for corrugated iron buildings is as follows: "Galvanizing on sheets furnished under this proposal must show a uniform surface, clean and smooth throughout and must weigh not less than 1.2 oz. on each side per square foot of area treated, and the lightest spot on any sheet must not fall below the above stipulated minimum."

I might add in conclusion that in my opinion galvanizing is a necessity in most climates, but we have found that in the San Joaquin Valley plain black iron will outlast other material which enters into the construction of a pole line.

E. A. QUINN,
*General Superintendent.*

---

**Kansas City Power & Light Company**
Kansas City, Mo.

We are using both galvanized and painted outdoor steel structures. We use the painted structures in some localities, such as isolated outdoor steel substations or places where the ground is high and there is not so much smoke as occurs in railroad districts. We find that two coats of paint—the first coat, say, of red lead and the second coat of carbon paint—will last two or three years. Paint on structural steel at lower elevations and in districts where there is a considerable amount of smoke from industries and railroads will barely last a year.

We find the cold process of galvanizing such as has been used around Kansas City unsatisfactory. Some of it showed evidences of rusting after a week. Hot-dip galvanizing, we have found, will last five years or more without any evidence of deterioration. This again, however, depends entirely on the location of the structure. We have no definite cost data on a comparative basis.

Our summers are rather warm and dry. In the fall, starting about the first of October, there is no wind, which tends to keep all of the impurities of the air near the ground. This seems to be the most severe condition of the year. Our winters usually are fairly mild. In general, I would not consider the climatic conditions very severe on the structural steel work.

We have had occasion to observe the difference in results between the use of graphite paint and of a carbon paint. There are several large oil

tanks along the river where the most severe condition that we have in our district exists, and we find that after one year's time the graphite paint shows a complete loss while the carbon paint shows no evidence of losing its value. These tanks are in a district where there are smoke and fogs from the river. A. E. BETTIS,
*Superintendent of Distribution.*

**New England Power Company**
Worcester, Mass.

It has been our practice during the last few years to galvanize all steel used on transmission lines. However, we have painted a great many of our steel structures for outdoor substations. The average life of the protective coat of paint is about three to four years. We have to date noticed no deterioration in galvanized structures, some in service fourteen years.

The cost of original painting and subsequent painting averages about ½ cent per pound of steel painted. The cost of galvanizing runs from 1 cent a pound up, depending on the tonnage of the individual orders.

Our system covers a large part of the central portion of New England, extending from Bellows Falls to the coast at Providence and Fall River. We have noticed no difference in deterioration on any part of the system to date.

It is necessary to paint steel structures every three or four years. This we do by scraping off all rust, following this by a protective coat of red lead on the scraped portion of the steel and then by a color coat over the whole structure. All our galvanizing has been done under the standard "B" specifications. C. R. OLIVER,
*Assistant General Manager.*

**Turners Falls Power & Electric Company**
Greenfield, Mass.

We have had experience with both painted and galvanized structures and recommend galvanized structures wherever bolted connections are allowed. On railroad crossings where riveted connections are made we use painted structures. Galvanizing in Seekonk and Somerset, Mass., on windmills is in good condition after twenty-five years. Painting is required about every three years where such structures are used.

Galvanizing increases the cost of the steel about 33⅓ per cent, but this is offset by the fact that we can use ¼-in. angles while painted structures use $\frac{5}{16}$-in. angles as a minimum. The cost of two field coats of paint is roughly $35 per ton.

We have a temperature range from — 20 deg. to + 90 deg. F. with high humidity, inland location and altitude from 50 ft. to 2,000 ft.

We use on our painted structures originally one shop and two field coats and repaint about every three years. Repairs consist of spot red oxide and one coat of paint (we have experimented with various kinds). Coal gas, salt water and acid fumes seriously affect painting. Galvanizing is done in accord with American Telephone & Telegraph Company specifications.
H. D. SEAVEY,
*Superintendent of Distribution.*

**Oklahoma Gas & Electric Company**
Oklahoma City, Okla.

We use both painted and galvanized outdoor structures. The average painted structure must be repainted about every two years. We have no definite data on the life of galvanizing. Our summers are rather warm with winters typical of the Southwest. All painted steel work receives one coat of graphite paint and two coats of aluminum paint when first installed, then each two years one coat of aluminum paint only is used. J. M. BROWN,
*Superintendent of Distribution.*

**The California Oregon Power Company**
Medford, Ore.

As far as line hardware and substation structures and power-house buildings are concerned, we use galvanizing instead of painting. We do not have sufficient data at hand to determine average life of this coating.

Climatic conditions in our territory are generally favorable to a long life for steel structures. The precipitation is in general light, the altitude comparatively high, and we do not have the salt atmosphere which causes deterioration of steel structures along the coast. The only data which we have in this connection are in regard to steel penstock pipes. We have a pipe line installed in 1903 and coated with an asphaltic dip. This coating is still in very good condition. We have another pipe line painted in 1912 with graphite paint, and this also appears to be in good condition. The steel pipe on Unit No. 1 of our Copco installation was painted in 1917 with a bitumastic paint, and we are at present repainting this pipe, although it is not in very bad condition. C. E. BLEE,
*Assistant Engineer.*

**Puget Sound Power & Light Company**
Seattle, Wash.

We use both galvanized and ungalvanized steel structures. The average life of the galvanized is rather uncertain and depends upon the character of the original paint, the method of handling during construction and the amount of fitting and damage done during construction.

The average life of galvanized structures could be taken as about nine or ten years; the life of protective paints, if a good type of paint is used and properly applied, could be taken as about five years. We have some steel towers in the vicinity of a smelter where galvanizing lasted only about a year and acid-proof paint coatings lasted only from one to two years.

The cost of galvanizing as compared with painting on steel towers is about nine times that of painting. I have no data on the comparative costs of galvanizing and of painting sheet-metal structures.

Our climate is damp with a good deal of salt air near the coast, and all painted structures are repainted about every four or five years. All galvanized structures should be inspected once a year for rust spots, and these should be thoroughly cleaned and a protective paint applied. S. C. LINDSAY,
*Engineer.*

**New Bedford Gas & Edison Light Company**
New Bedford, Mass.

We cannot give you any accurate data on the relative merits of galvanized and painted structures. Though we have both types of structures in and about our plant under varying degrees of exposure to weather and salt fogs, we have not made a record of the results obtained. We have some galvanized structures quite near the seacoast, and also painted structures, but no satisfactory statement can be made regarding their relative merits as regards the protection of the iron.
DAVID W. BEAMAN,
*Supt. Electrical Department.*

**United Hudson Electric Corporation**
Poughkeepsie, N. Y

Most of the outdoor substation structures erected during the past three years have been galvanized. The few exceptions that have been painted during this period already need repainting. Prior to 1920 all such structures were painted. All transmission-line towers are galvanized with the exception of a few narrow-based steel poles erected about five years ago, which are painted with a shop coat of red lead and linseed oil and a field coat of black graphite paint.

The average life of paint as an effective protective coating on outdoor substations is about three years. Generally speaking, the use of galvanizing as a protective coating is of such recent practice with this company that no statement of its life can be made. However, galvanized transmission towers in service since 1917 are today apparently as good as new. Ground-wire bayonets, composed of 2½-in. x 2½-in. x $\frac{3}{16}$-in. angles, galvanized about ten or twelve years ago are still in excellent condition. The expectation is that galvanizing as compared with painting will justify itself in about six years.

Climatic conditions are not unusually severe. Most fogs are fresh mountain mists, and it is doubtful if any of the salt fogs of the coast reach this territory. Very little trouble from industrial fumes is experienced. The worst conditions are in cases where the towers cross or parallel railroads, and these cases are causing no trouble.

Painting of outdoor substation structures is done about once every three years. The paint used is generally of lead or graphite pigment with linseed oil, though no standard practice has been developed. Galvanizing is in accordance with N. E. L. A. specifications.

# Line Regulation and Power Factor Correction

### Effect of Line Voltage Changes on Loads of Various Kinds, Particularly Those Arising with the Employment of Power-Factor Corrective Devices

BY CLIFFORD W. BATES
Research Engineer, Philadelphia Electric Company

WHEN considering the installation of condensers to improve the power factor of a system, it is important to consider the effect of voltage variation on the amount of correction obtained, particularly as the effect is quite different on the two available types of apparatus in use—the static condenser and the so-called synchronous condenser. It is also interesting to note the effect of voltage variations on the input to loads of various kinds.

The static condenser behaves exactly like a resistance of any type, such as lights, heating devices, etc.; that is, the current is directly proportional to the voltage and the kva. input or kw. input in the case of heating devices is proportional to the square of the voltage.

Synchronous condensers, on the other hand, being essentially synchronous motors operated at no load with the field overexcited, behave very differently. If the line voltage increases with the excitation remaining the same, the current and kva. input fall, since the increase of voltage is equivalent to a relative decrease of overexcitation. In fact, if the line voltage should increase so as to equal the voltage to which the motor is excited, the current would be reduced to zero, except for the small power component necessary to drive the motor, and a further increase would result in a lagging current. A decrease in line voltage operates in exactly the opposite way, as this is equivalent to a relative increase in the overexcitation. The magnitude of the change depends to some extent on the design of the condenser. The curves given in the analysis correspond to a motor having 50 per cent synchronous impedance.

Induction motors vary considerably in their characteristics, depending principally on the type (squirrel-cage or wound-rotor) and on the size. The curves of Figs. 1 and 2 are based on a 20-hp. squirrel-cage induction motor of average characteristics. They are based on constant torque duty, such as driving machine tools and hoists, but the values were calculated for the motor driving a fan, for which the torque varies as the square of the speed, and are found to differ very little from the constant-torque values for the range of voltage variation included by these curves.

The very small change in the power input to induction motors as the motor voltage varies from 20 per cent below to 20 per cent above normal is particularly striking. This is mainly due to the fact that the speed change is comparatively small within this range, and that any variation of power taken by the load from the motor depends on the speed. Although the output does decrease slightly because of reduced speed the losses increase in such a way as practically to neutralize this decrease. The reactive component, on the contrary, decreases rapidly with a decrease of voltage.

In the case of synchronous motors the power output is independent of voltage variations and the power input is virtually so. The power component of the current will then vary in inverse proportion with the voltage. The reactive component will vary in general like that of a synchronous condenser.

### CONCLUSIONS

The curves show that the synchronous condenser is more effective under variable voltage conditions than the static condenser. The correction afforded by the static condenser tends to decrease at the very time when it is needed most, while that given by the synchronous condenser increases even more rapidly than the voltage decreases, thus automatically compensating to some extent for the drop in voltage, particularly if this drop be due to a heavy overload at low power factor. However, the use of static condensers should not be entirely condemned as their relatively lower losses, the decrease in amount of attendance necessary and their smaller bulk, together with their lower cost in the small sizes, may often result in a static condenser being installed for correction purposes in a location where no condenser would be installed if the synchronous condenser were the only type available.

# Industrial Electric Heat Applications—I*

## A General Résumé of Industrial Heating-Oven Practice—The Solution of the Control Problem and Limitations in Furnace Applications—Different Types of Furnaces in Use

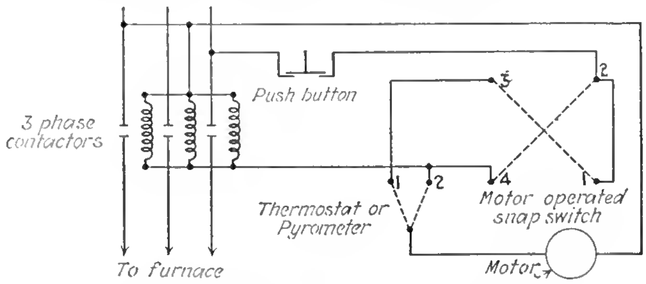
By J. L. McK. YARDLEY
*General Engineer Westinghouse Electric & Manufacturing Company*

IT IS difficult to astonish any one with the achievements in any branch of the electrical industry. Frequently a sprout from the parent tree has grown unnoticed until it has acquired a magnitude that compels comment. In fact, the tendency now is to heap public encomiums on everything accomplished electrically, independently of comparative merit.

One of the most recent activities of the electrical industry is connected with the electric furnace or oven and its application to industrial heating purposes. In the face of fierce competition this activity has won a secure place and has an encouraging outlook. Yet the art is not sufficiently advanced or the economical situation sufficiently sound to warrant predictions to the effect that it will or even should be the universal agency for industrial heating. Each application and industry affords a specific occasion for engineering and economic analysis before a decision can be rendered intelligently.

It seems unquestionable that the field of industrial heating by electricity will expand greatly, owing to the abundance, cheapness and reliability of electric power and to the superior results of one kind or another which are often experienced. Because of these results it will extend particularly and quickly in the industries in which it has already started. The other industries and new applications must be approached by experts capable of applying both economics and science with good judgment to the problem.

Many improvements are being and will be made in fuel-fired furnaces to meet the competition of electric furnaces. Much of the improved thermal efficiency of the electric furnace attained by the use of large quantities of improved heat-insulation materials may also be attained with fuel-fired furnaces, the design of which has been improved to include similar qualities of the same insulation materials. The essential factor is that in industry, in the final analysis, the foremost consideration is over-all cost. Another point to consider frankly is that whereas, theoretically, the atmosphere in the electric furnace chamber may be whatever is desired, practically, using the metallic resistor furnace, it is exceedingly difficult to have anything but a somewhat oxidizing atmosphere in the furnace chamber. This fact makes some process applications, as, for example, the bright annealing of steel, formidable problems for the electric furnace, such as can be and will be worked out only by experts.



SCHEMATIC DIAGRAM OF THERMOSTATIC OR PYROMETER CONTROL OF CONTACTORS FOR INDUSTRIAL OVENS

The thermostat is at 1 and the motor switch at 4-2. To start the furnace the push-button is closed, closing the control circuit through the coils of the contactor, which then closes and connects power to the resistors. When the furnace reaches a predetermined temperature the thermostat makes contact at 2 and closes the circuit through the motor-operated snap switch, which moves to position 1-3. This breaks the contactor-coil circuits, opens the contactors and opens the circuit of the motor-operated switch. As the furnace cools the thermostat goes back to position 1, which causes the motor switch to return to position 4-2. The angle then repeats itself.

The industrial oven or furnace, of course, consists essentially of some electrical resistor material and some heat-insulation material carried in a metal frame for mechanical support. Many kinds, types and varieties have been produced. The fundamental material is the resistor, and the table shows some of the kinds now used or suggested for use in industrial furnaces.

The heat insulation materials have gained great prominence in recent days, because they directly affect the thermal efficiency of the oven. There are a great many materials used commercially, such, for example, as (1) mineral wool, which is a product of silica, alumina and iron oxide, made by blowing a powerful jet of air or steam through blast furnace slag, and (2) insulating bricks of various kinds, such as "Sil-O-Cel," "Insulbrix" and "Nonpareil." As refractories, or material that is close to the heating elements in

TABLE I—ELECTRICAL RESISTOR MATERIALS

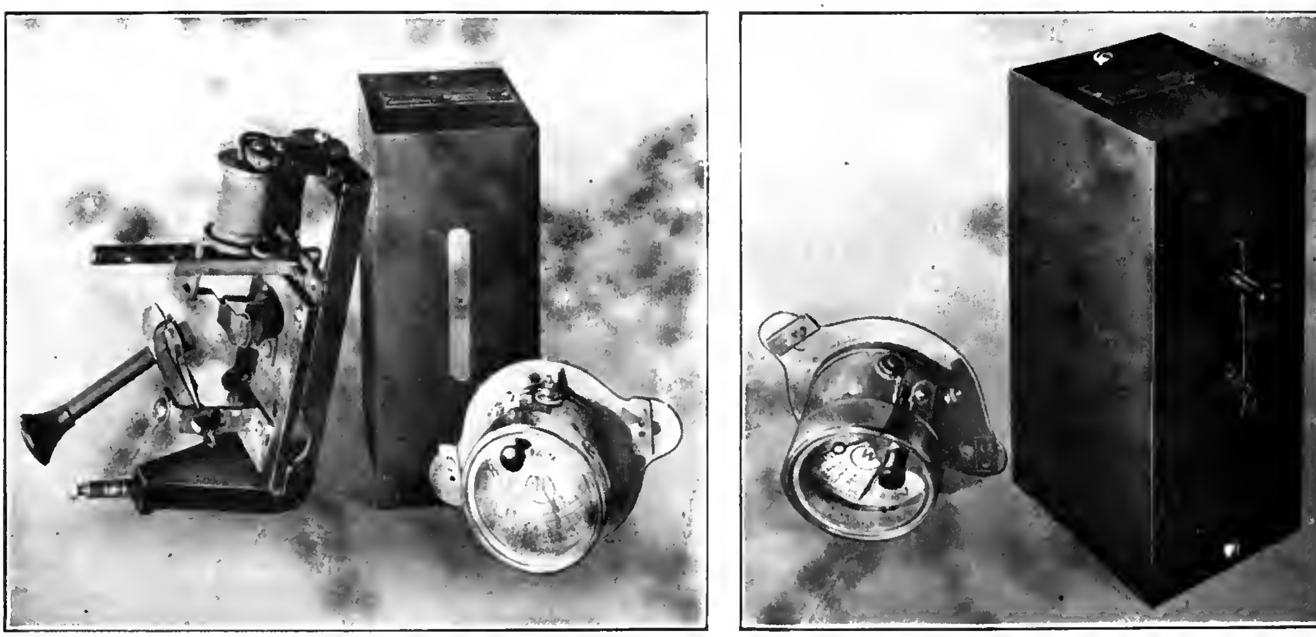
| Type | Content | General Remarks |
|---|---|---|
| Nichrome | 60 to 66 per cent nickel<br>12 to 22 per cent chromium<br>26 to 10 per cent iron<br>2 per cent manganese | Maximum working temperature of resistors about 1,800 deg. F. |
| Chrome or No. 1 chrome-nickel alloy | 80 per cent nickel<br>20 per cent chromium | Contains no iron or other impurity; highly acid-resisting and has high resistance to oxidation; maximum working temperature of resistors 2,000 deg. F. |
| Nickel-steel or ferro-nickel alloy | 25 per cent nickel<br>75 per cent iron | Maximum working temperature of resistors 1,100 deg. F. |
| Copper-nickel alloy | 45 to 65 per cent nickel<br>30 to 55 per cent copper | Maximum working temperature of resistors 900 deg. to 1,100 deg. F., and practically negligible temperature coefficient of resistance. |
| Carbon-granular or plate | Carbon | Maximum working temperature about 5,500 deg. F. |
| Carborundum | Amorphous carbon | Not a commercial success; decomposition occurs at about 4,000 deg. F., but hot spots develop so that furnace temperatures seldom exceed 2,500 deg. F. |

high-temperature furnaces, "Star" silica brick, "Quartzite" brick, first-quality "Woodland" brick, "Carbofrax" brick and other materials are used. Some of the insulating bricks weigh about 30 lb. per cubic foot, whereas the refractory brick weighs about four times this amount.

One of the problems of the industrial oven and furnace has been to determine the temperature with the degree of precision required. It is practically a universal practice to use the thermocouple up to 2,500 deg. F. The base-metal thermocouple usually is made of constantin and iron or nickel chromium and nickel alloy and is used up to 2,000 deg. F., although it deteriorates rapidly above 1,800 deg. F. The platinum or platinum-rhodium thermocouple is used up to 2,500 deg. or 3,000 deg. F., while the optical pyrometer is used above 2,500 deg. F. The base-metal resistance is not so constant, but the electromotive force is as constant as in the platinum theromocouple and several times greater. Readings are obtained by galvanometric or potentiometer methods.

steel sheath. The flanges of this sheath are pressed down with a 10-ton pressure, and upon installation of the terminals the space heater is complete. The individual heating element is made in several sizes up to 1,250 watts, and the maximum operating temperature is about 1,000 deg. F. or 800 deg. F. at the work. In the steel-clad heater a punched ribbon resistor of nickel steel is employed. This is laid flat between sheaths of mica insulation. For this type the maximum operating temperature is about 600 deg. F., or 450 deg. F. at the work. These elements are made in several sizes up to 1,000 watts. The terminals are at one end so the heaters may more readily be inserted in the work.

The space heater is employed in a great variety of applications. It may be assembled in any desired numbers, depending upon the purpose for which it is to be used. One particular purpose is for use in air heating. Other applications of the space heater or steel-clad heater are in foot warmers, such as are used in traffic regulation, industrial hot tables and restaurant grills,



A SAFETY THERMOSTAT CIRCUIT BREAKER FOR CONNECTION IN THE CONTROL CIRCUIT OF AN OVEN OR FURNACE—COVER ON OR COVER OFF

The resistor materials are arranged in some manner to form unit heating elements. Of these one of the most common is the grid-type heater made of nickel steel for immersion in oil, fats and greases. Still another is called the cartridge type, which consists of nichrome resistors wound on fireclay insulation and mounted in brass shells of various diameters to fit holes of different sizes. The wattage runs from 75 to 1,000 per heater and the maximum operating temperature is around 900 deg. F.; that is, 750 deg. F. at the work. These heaters are used in special machinery applications, largely in the rubber and shoe industries.

Still other types of heaters are the steel-clad and space heaters. These are so named because the heating elements are incased in steel and are designed to economize in space occupied. Mica insulation is employed for the space heater. The mica sheet is rolled into a tube on which the nichrome resistance ribbon is then wound. The tube is flattened, one terminal is placed at each end, and the flattened tube is then placed in a mica sheath, which in turn is placed in a heavy sheet-

heating of water tanks, mangle shoes and heating of pattern plates in molding machines.

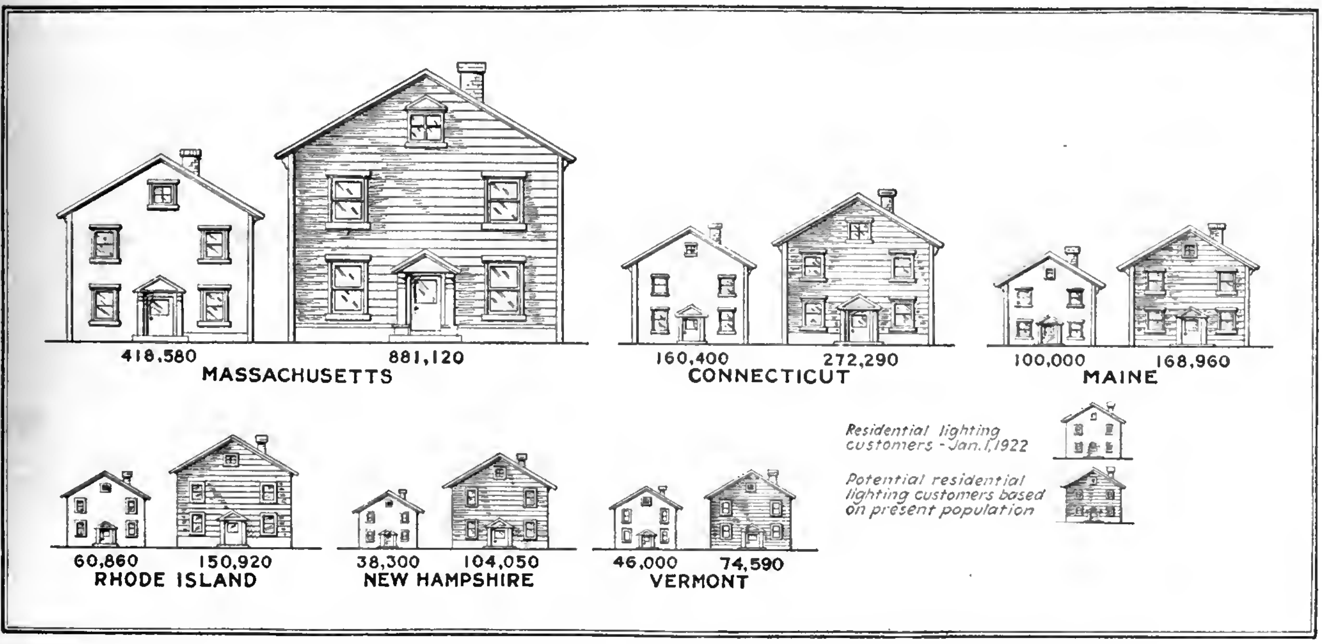
Still another type of heater is the industrial-oven heater. This consists of a nichrome resistance ribbon wound on fireclay insulators and mounted in a steel-rack frame of open construction. The element is made in various sizes from 1¾ kw. to 5 kw. for 110/220-volt service. The maximum operating temperature is around 900 deg. F., or 700 deg. F. at the work. Standard connectors and hooks for hanging in position are provided, and two 110-volt heating elements may be connected in series to operate on 220 volts, single-phase, or two 220-volt heating elements may be connected in series to operate on 440 volts, single-phase. Six 110-volt heating elements may be connected three-phase for operation either on 110-volt or on 220-volt, three-phase circuits. The installation and the connection of these heaters in the industrial ovens is a very simple matter indeed.

The control of the electric heating oven is a very important part of the operating process. As previ-

ously indicated, this is insured by means of the thermostat, or thermocouple and controlling pyrometer if the temperature is high. For a small industrial-oven installation a single-section control panel is employed. For example, for a capacity of 40 kw., or the equivalent of 120 amp., three-phase, 220 volts a single panel is used. For a larger oven or furnace installation individual section control panels are grouped into a board. For example, 2,200 kw. of heat at 550 volts employed in air heating in a large cotton mill of the Canadian Cotton Company near St. Stephen's, N. B., is controlled from two switchboards into which the individual sections are grouped. When grouping the control in this way the sectionalizing switches are usually segregated at one part of the board and the main automatic control contactors at another part. In some installations it is considered desirable to have a safety thermostatic circuit breaker connected in the regular control circuit in such a manner as to cause the opening of the main contactor in case the temperature accidentally becomes too high. This feature has been employed especially in armature insulation baking.

# Potential Customers in New England Total 2,069,000

"Electrical World's" Estimate of Present and Potential Customers of the New England States by Counties Indicates that a Total of About 48.3 per Cent of the Homes in This Section Are Electrified



IT IS POSSIBLE FOR THE NEW ENGLAND CENTRAL STATIONS AS A WHOLE TO DOUBLE THE PRESENT NUMBER OF DOMESTIC LIGHTING CUSTOMERS

ONE of the greatest problems involved in the distribution of electrical energy and of electrical apparatus and supplies is to obtain a reasonably accurate and detailed knowledge of the extent of the present market and of the potential possibilities of the market which is to be served. Given such a basis, it is a comparatively simple matter to apportion this market and to lay plans to take care of its future development.

With the idea of supplying this need, the ELECTRICAL WORLD has initiated a series of investigations which it is hoped will give the industry a reasonably accurate basis for ascertaining the extent of the present market for electrical energy and electrical apparatus and supplies in any desired locality and also for prognosticating the future market in that locality.

The first study undertaken is a segregation of the present central-station customers into the various counties of the states and an estimate of the potential number of the various classes of customers in each county under present conditions of population. Such figures are presented in the accompanying table for the various counties of the six New England States.

This study is based upon reports which have been received by the ELECTRICAL WORLD from operating companies representing about 70 per cent of the installed generator rating of the country supplemented by population and industrial power data issued by the United States Census Bureau. The data obtained in this way were referred to a representative company operating in the county concerned with the request that an opinion be given as to whether the data represent with a fair degree of accuracy conditions existent in that county. In the few cases where the company to which the figures were sent indicated that the ELECTRICAL WORLD figures were at variance with conditions in the

county a new study was made and the data were corrected accordingly.

The method used in determining the number of potential residential lighting customers, potential commercial lighting customers and potential industrial power customers was adopted after careful study. To arrive at the number of potential domestic lighting customers of any county it was assumed that all the families residing in the urban districts of that county fall within this category. It was also assumed that all the families residing in rural towns are potential domestic lighting customers, and that 50 per cent of the remaining families in rural districts are potential customers. Adding these three quantities gives the total potential domestic lighting customers of the county.

The number of potential commercial lighting customers was estimated by determining the present number of commercial lighting customers in the towns and cities reached by central-station lines and assuming that this number bears the same relation to the potential commercial lighting customers as the present number of domestic lighting customers in these towns and cities bears to the number of potential domestic lighting customers.

## Present and Potential Central-Station Customers in the New England States by Counties

| State and County | Population (Census of 1920) | | | Domestic Lighting Customers | | Commercial Lighting Customers | | Industrial Power Customers | |
|---|---|---|---|---|---|---|---|---|---|

## Need of Closer Relations Between Operating Companies and Educational Institutions — Mutual Benefits of Co-operative Courses— What Is Being Done by the Brooklyn Edison Company

By M. S. SLOAN
*President Brooklyn Edison Company*

TECHNICAL training has progressed in the past thirty or forty years to the point where the graduate of a two-year industrial training course probably knows more about electricity than Edison did when he built the Pearl Street station in New York City. What will the future require of men entering the industry in comparison with our present needs?

We must sharply differentiate between the two types of educational institutions and the two types of training for which we have use in our industry. First and more extensive, there is the trade or vocational training, which fits men for various manual or semi-manual employments, which produces the rank and file and the non-commissioned officers of the industry; second, there is the professional or university training which provides staff and line officers.

There are in the country today a few good vocational schools—all too few, be it said. To these we should give every possible encouragement and guidance, and to them our industry can offer very much in the way of direct, specific, tangible help. These schools take young men fresh from high school, or without even a high-school diploma, give them familiarity with the specific arts and methods of the various industries, train them in process, acquaint them with fact and incidentally teach them how to think.

To such schools we can supply much detailed information concerning the needs of our industry. For them we can supply opportunity for inspection trips and to some degree field tests. With them it is possible for us to develop co-operative relations wherein the students may be employed on part time on our properties. To them we can send some of our more promising men for night or part-time day instruction, ourselves deriving a direct benefit through specific individuals among the student body.

### Fundamentals Basis in Professional Training

In the other class stand the great professional schools and universities which, on more or less rigid entrance requirements, admit students from preparatory schools, which give those students training intended not primarily to make them of direct value to my company or to yours, to this particular industry or to that; but which do plan with a certain amount of training in the specific arts to produce first a trained mind, the power to observe, intellectual vigor and a sense of discrimination.

Our service to such schools and the service which we may expect to receive from them must of necessity be indirect, somewhat intangible and general in character. As these schools do not pretend to communicate to their students the specific and immediate facts of today concerning the industry, what we can contribute to them in the way of information must of necessity be of value only as the faculties themselves can use this information as source material on which to base their educational process. Remote and intangible though such co-operative effort must of necessity be, it is at the same time well worth the making.

I am profoundly convinced that much of the difficulty which we have had with the so-called socialistic college professor is not a result of any fundamental incapacity to think or of perversity of either spirit or mind, but is rather the direct consequence of the fact that he does not know either the facts of our industry or us as individuals. Anything we can do, then, to bring ourselves in touch with professors of economics and business administration, of law and political science, in our institutions of higher learning will, unless our industry is on a lower plane than I conceive it to be, have the effect of giving these men the opportunity which they as searching apostles of truth should, and I believe do, welcome to get the basic facts from which their conclusions must be drawn.

The academic mind runs pretty straight once started in the right direction, but given an initial prejudice, runs equally straight under that impetus.

### Research Fellowships Point the Way

I can conceive of no greater co-operative service, valuable alike to our universities as institutions where above all else the truth is esteemed and to us, who desire above all else that the truth about us shall be believed, than that we should, through the establishment of research fellowships, offer our industry as source material for graduate students and professors competent to make a study of public utility problems. More will be heard of this in the not distant future through the N. E. L. A. committee on co-operation with educational institutions, in whose work my own company is taking a very active interest.

Both in industry and in academic circles there is a persistent query as to what the schools can do for industry, meaning thereby what direct, tangible things the schools can do to stimulate our industrial activities and to increase our prosperity. Without disparagement of the value of research and of the solution of our specific problems, I suggest that the greatest service which any school can possibly render to the nation and to industry is to be an *educational* institution. The chief reason for the existence of our universities is to prepare young men for life and for the service of society. So long as specific undertakings contribute to that purpose, these specific undertakings are to be encouraged; but above all else, if our civilization is to be progressive, the schools must produce men who can advance human knowledge and the application of it to the well-being of humanity.

Many young men fresh from college have a tremen-

*From a paper presented before the New England Division of the N. E. L. A. at a public policy session in Boston, March 8, 1923.

dous store of "facts" which would be so if they were true! They know how to design anything from a major power plant up, but do not have their feet securely on the ground when it come to rigorous thinking from facts carefully observed. We must encourage our colleges to teach little, to teach that little well, and to develop in the students the habit of work.

In earlier days young men gained their acquaintance with our industries through apprenticeships at nominal wage, at no wage at all, or sometimes even paying for the privilege. That day is past. The young man fresh from college can today earn a living wage which will enable him to keep body and soul together until he has developed some practical value. I believe it to be our responsibility to create more full opportunity for the modern equivalent of the old type of apprenticeship —something after the fashion earlier established by the Santa Fé Railroad and by the great manufacturing companies in the electrical industry. My own company now has in formation a cadet course for college graduates. We may take on more young men than we can ultimately absorb. Future opportunity for them must be created either by graduating out of the company bureau heads who can go to larger responsibility with other concerns or through losing some of our cadets after a year or two of experience with us. What we have invested in the entire group will doubtless be repaid through an opportunity to select from the group whatever percentage we are able ultimately to retain.

#### Co-operation with the Brooklyn Polytechnic

With the other type of institution and with its possibilities of service to us we have had nearly a year of actual experience. We formerly had in our company an educational department internally manned. For various reasons the results were not altogether satisfactory. We have in Brooklyn one of the best of semi-vocational schools—the Brooklyn Polytechnic Institute. Like few other institutions of its class, it approaches closely to the university standard. This institute is headed by Dr. F. W. Atkinson, a man of the highest attainments, of broad perspective, a splendid administrator, and with an admirable faculty under him. Being peculiarly a Brooklyn organization and convenient to our work it occurred to me as a trustee of the institute that the Brooklyn Edison Company might profitably use it in improving the utility's training courses.

We created in the department of economics and statistics a Bureau of Education, under the immediate supervision of Prof. Robin Beach of the institute's electrical engineering department. In the educational work given to company employees we have been able to utilize members of the institute faculty and company employees. The former have been placed on the company payroll at modest but at the same time adequate salaries. Some twenty-five of our own employees, department and bureau heads for the most part, are used as special instructors and lecturers. To these latter we pay an "honorarium" of $5 per evening. Courses are offered under two general classifications, technical and commercial. The former cover such subjects as the elements of electricity, direct-current and alternating-current machinery, meter practice, principles of combustion, switchboard operation and industrial applications. The latter include such topics as sales of electrical appliances, theory and practice of filing, personnel and office efficiency, accounting, general organization, sales department organization and English.

Although most of these courses are offered in the evening, some are given at daytime hours convenient to men working on the night shift. Usually the sessions last one hour, but two hours are allotted to laboratory sessions. Four courses last about eight weeks, but most of them run twenty-five weeks.

#### One-fifth of the Brooklyn Edison Company Employees Enrolled

Against 209 enrolled students in company courses last year, we now have 934 enrolled in the co-operative courses. The course elections last year were 217; now they are 1,364. Twenty-one and one-half per cent of our employees are registered in courses, the secretary's department having a 71 per cent enrollment, one engineering department 57 per cent and the sales department 44 per cent. Attendance and interest have been most satisfactory.

As this work is vocational training and not a process of general education, we are attempting to relate the subject matter of the courses as closely as may be to the specific problems occurring in the company's work. I do not believe that good results flow from doing so much for an employee as to make him feel that he is the subject of a kindly paternalism. We have, therefore, required those enrolling to pay a fee at the time of electing the course, but in recognition of the earnestness and application of those who complete the courses satisfactorily the fee is refunded at the conclusion of the instruction.

While it is too early to discuss definite results, I and all my department heads are sensible of certain benefits which were predicted by Professor Beach. These are mutual to the institute and to the company. The advantages to the company reside in the fact that under a centralized system of company industrial education employees are efficiently, economically, expeditiously and consistently trained to perform their duties. Their perspective becomes broadened so that they grasp better the relation of their work to the general activities of the company. Whatever increases the earning capacity of employees increases their value to the company. This educational opportunity serves to draw together employees of different departments in a common undertaking, thereby promoting mutual appreciation.

Our practical men, on the other hand, communicate through their lectures something which the schoolmen can use with a great deal of advantage in their regular work in the institute. We have gladly placed at the disposal of the institute much of our machinery and equipment and have encouraged inspections of our properties by faculty and students. The faculty derives opportunity to keep in touch with our most recent advances, to gage the needs of at least one industry and to find an outlet for institute graduates. We are incidentally creating some opportunity for the institute instructors to collaborate with our engineers and investigators on certain special problems.

I do not mean to say that we have worked this problem through to anything like its final conclusion, but the results are so good that we cannot consider as anything other than profitable the increase of our 1921-1922 educational budget from $12,000 to $17,000 for 1922-1923, and I am not in the least degree hesitant in suggesting that no company which has closely at hand such an institution as the Brooklyn Polytechnic Institute can afford not to utilize its faculties and its laboratories in carrying on a company educational program.

# Experience with the Radiophone

## First Report of Any Length Relating the San Joaquin Light & Power Corporation's Experience with Radio—Conditions that Led to the Adoption of Equipment—50-Watt Tubes Used—Consistent Reception Reported from Distance

By R. C. DENNY

*Operating Engineer San Joaquin Light & Power Corporation, Fresno, Calif.*

COGNIZANT of the need of an emergency means of communication to carry on system dispatching during periods when the telephone lines were from any case disabled, the San Joaquin Light & Power Corporation of Fresno, Cal., in the fall of 1921 undertook the development of a practical radiophone. The chief requirement in such an instrument was that of consistent operation day or night over a maximum radius of 135 miles from the dispatcher's office at Fresno in a southwesterly direction. The distance requirements in other directions were approximately half as great, but, owing to the fact that these shorter distances were over a mountainous country into deep canyons, the requirements were quite severe, nevertheless.

The fact that transmission was desired in all directions out from the operating center of the system rather eliminated the "wired wireless" or carrier-current system, with its limitations, from consideration. Moreover, the failure of communication is in the majority of cases incidental or secondary to failures of the transmission lines, which, in case either telephone lines or transmission lines were used for the purpose, would render the carrier system useless just at the time it was most needed.

### System Used Must Be Reliable in Emergencies

Obviously, then, to be practicable under the most adverse conditions emergency communication must be entirely separate and independent of the lines. Manifestly, it is only adverse conditions constituting emergencies that really justify any system of radio, as fully 95 per cent of the time the line telephone system functions properly and is entirely adequate. Therefore, in view of the notorious inefficiency of radio transmission, it would seem extremely uneconomical to use any form of radio where the telephone would suffice, except, of course, for emergencies.

Particularly is this true in cases in which radio is applied to systems where telephone lines already exist and where they are strung beneath the transmission lines. It is admittedly a fact that on new projects where long transmission lines are to be built the carrier-current telephone system may be used for routine work over the transmission conductors in lieu of building separate telephone lines. A saving can be thus effected provided that the initial cost of the carrier-current apparatus is kept down within reason. However, unless the transmission lines are provided in duplicate it is rather doubtful whether the carrier system would suffice in the case of line failures where one or several spans have come down or are tangled up and grounded.

Thus it is very dubious whether the carrier-current system will be of any great value in emergencies. At any rate, it becomes rather apparent that each of the two systems of communication has its own field—the radiophone where an extensive interconnected transmission network of one, two or three voltages is to be talked over in any or all directions, and the carrier-current scheme for talking over especiallly long and important transmission lines where communication is desired only at the terminals. In fact, several companies are adapting the carrier-current system to certain more important stretches of their transmission system because of the government radio regulations, which are rather inclined to handicap the use of the radiophone even for emergency operation. Whether carrier current will prove entirely successful in emergencies is yet to be demonstrated.

FRONT AND REAR VIEWS OF 50-WATT RADIOPHONE SET

The power tubes and rectifiers are mounted on the top shelf, the oscillatory circuits and apparatus on the next shelf, the filter and choke system below, and the power supply equipment on the bottom shelf.

Another requirement to be met in the development of a practical radiophone for emergency use was that it should not cost one whit more than was commensurable with successful and consistent operation. Still another was that it should be simple in operation and adjustments and involve low maintenance expense. With these and the distance requirements in mind the writer set about the development of such a radio-telephone set. At that time, and with only the experiences of two other radio-telephone installations to be judged from, it was

decided that a set of 50 watts output rating, if that output were properly modulated, would meet the distance requirements. Advice from several of the large manufacturers that at least 250 watts would be required, and that 1,000 watts was recommended, did not affect the original decision.

From the outset it was decided to eliminate the one item of greatest expense formerly used in such sets, that being the motor-generator set for the production of high-voltage direct current. Experiments with an electrolytic rectifier proved conclusively that alternating current could be used if the resultant pulsating direct current could be sufficiently filtered or smoothed out to minimize if not eliminate the fundamental hum. It was soon demonstrated, though, that, because of overheating, the chemical device for rectification was inadequate for constant use on currents even as low as 300 milliamperes at 1,000 volts. Besides being very inefficient, it was cumbersome and "mussy," which militated against its use in a compact and finished set. Having served the very useful purpose of demonstrating the possibilities of rectified alternating current, it was discarded in favor of vacuum-tube rectifiers.

### Heat Filaments with Alternating Current

It was also very desirable to use alternating current for heating the filaments of the various vacuum tubes to be used in the set. Besides being more economical than using storage batteries and much more simple as well than low-voltage generators, and more easily regulated, it actually results in a longer filament life as emission is more even from all parts of the filament. In actual service it was found very feasible to use alternating current for this purpose if certain precautions were taken. One was to bring out the center tap of the transformer winding for connection with the negative high-voltage lead which forms the negative or common connection for the entire set. Telephone condensers rated at 1 mf. should be bridged across from this center tap to each end of the winding, these to serve as a low-impedance path or bypass for the high-frequency currents from the oscillator tube. Ordinary potential transformers were rebuilt or remodeled for the purposes of filament heating and high voltage for the rectifier, and these, too, proved to be inadequate owing to overheating when used continuously. However, they served their purpose, permitting the experiments to be carried on while properly designed apparatus of adequate capacity was being developed.

One thing that became apparent in the early stages of the experiments was the necessity for low antenna resistance. An aërial and ground system that had been perfectly satisfactory for the spark system of radio telegraphy, employing spark frequencies on the order of 1,000 per second, would not serve at all for the high frequency of the radiophone carrier wave, which was something over 833,000 cycles at the particular wave length at which the experiments were carried on. Accordingly a counter-capacity antenna or counterpoise was designed having the same physical dimensions as the antenna and erected directly beneath it and parallel to it at a distance of 40 ft., this being influenced by local conditions. Every precaution was taken to keep the ohmic resistance as low as possible, stranded copper conductors being used, heavy leads employed and all joints soldered. A marked increase in radiation was the result, practically three and one-half times the former current. It was found possible to increase the radiation further by connecting the ground lead to a certain point on the inductance coil, so that with the combination of counterpoise and ground connection radiation was four times that obtained with ground alone.

In order to bring in reports from all directions on the operations during the experimental development of the radiophone it was necessary to do a certain amount of broadcasting. Another and fully as important reason for broadcasting was to stimulate an interest in radio among the power-house and substation employees about the system. It was considered that such interest was vitally important to the successful future operation of an emergency radiophone service. This was done under an experimental license until a ruling of the Department of Commerce necessitated taking out a special broadcasting license for the purpose. It was thus that the company's broadcasting station KMJ came into existence, but with the idea of a broadcasting station secondary to the development of the set for use in emergency communication.

After many months of delay occasioned by the inability to get satisfactory tubes and apparatus, hardly any of which were more than out of the experimental stage and on a production basis, a complete set of standard parts was evolved. A satisfactory filter system had in this time been developed, utilizing the primary winding of a 1-kw., 2,300-volt distribution transformer as a choke, the two coils each in series with one side of the rectified high-voltage supply. Three 1-mf. condensers insulated for 1,750 volts were shunted across this circuit on the power side and one on the radio side.

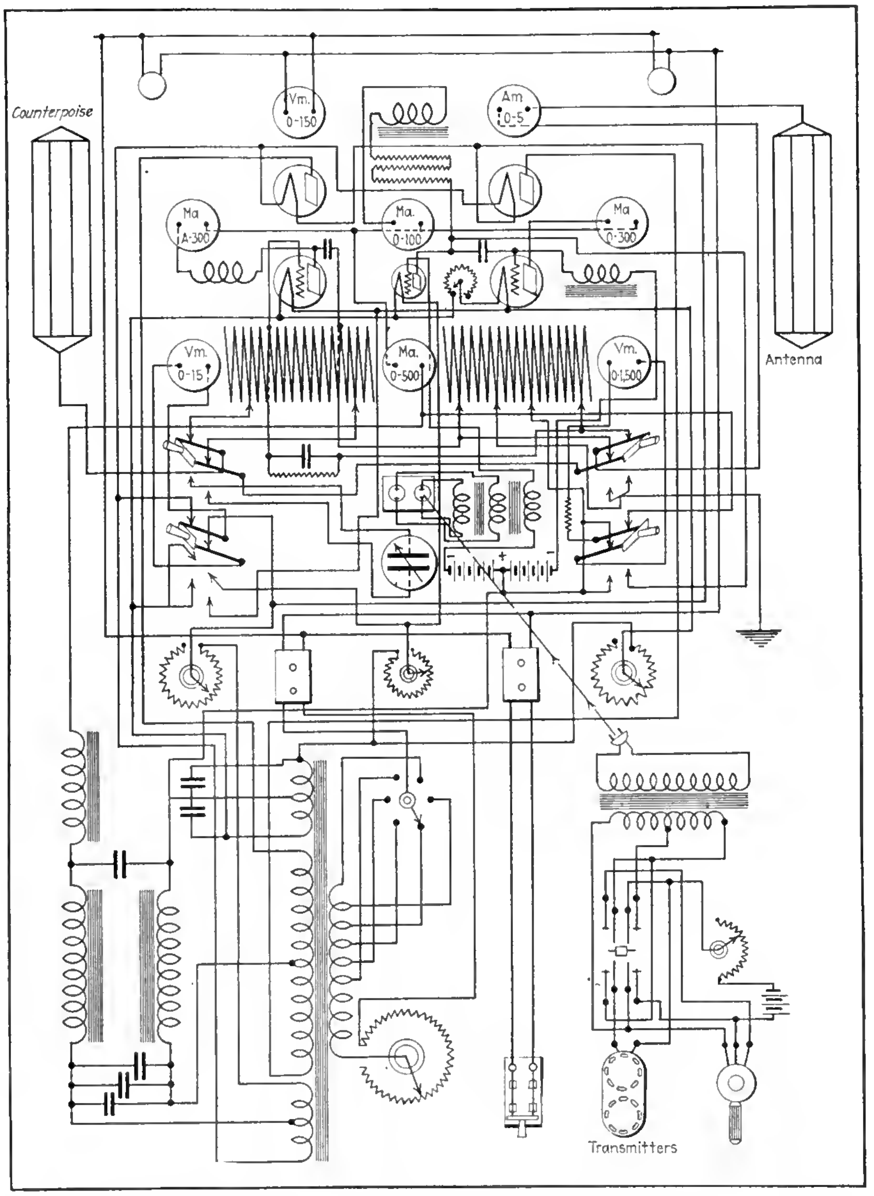
A special but standard transformer of 750 watts rating was used for the one source of power. This transformer has one primary winding, with taps for operation on from 102.5 volts to 115 volts, and three secondary windings, two of which give 10.5 volts for filament heating and one 3,000 volts for the rectifier tubes. Each of these secondary windings has its center tap brought out, a connection which is absolutely essential. It was found in actual practice that this transformer, which is of the dry type, when operating continuously at just full load for an hour at a time became dangerously hot. For this reason it was necessary to rearrange the terminal connections, soldering on long leads and sawing out sections of the end shells preparing the transformer for operation under oil. It was put into a 1-kw. distribution transformer case, submerged in oil, and the operation since has been entirely satisfactory. Owing to the primary voltage sometimes going above the transformer voltage rating, a 40-ohm rheostat is provided in the primary circuit.

Power for the set is supplied from the 115-volt lighting circuit of 60 cycles frequency. Entering the set through a fused knife switch it passes through a flush-type lock switch to the main power bus and thence to the bracket lamps and alternating-current voltmeter. This meter indicates which voltage tap to work on, so the tap selector switch is moved to the proper point and with the primary resistance all in the flush push switch is snapped on. The primary resistance is then cut out gradually and the set brought up to normal operation.

Power tubes of 50 watts output rating are used, one as an oscillator and the other as the modulator. The constant-current system of modulation is used in connection with a 5-watt speech amplifier. A special reactor

of 300 milliamperes capacity is used in the main positive lead to the plates. The power tubes require at least 1,000 volts on the plates, while the speech amplifier tube requires 350. A resistance of 15,000 ohms having a continuous carrying capacity of at least 50 milliamperes was found necessary to reduce the voltage to the proper value. This resistance was composed of three standard 5,000-ohm resistors. A direct-current voltmeter is provided which by means of a double-pole, double-throw switch may be thrown on the power-tube plate circuit or upon that of the amplifier tube. The rectifier tubes have an output rating of 150 watts each, and the two carry a load of 300 milliamperes at 1,300 volts without undue heating. Two standard rheostats of 15-amp. continuous carrying capacity are provided, one for each set of tubes that operate in multiple. An additional rheostat is provided for the modulator tube, which sometimes requires a slightly different adjustment from the oscillator. A separate rheostat is provided for the speech-amplifier tube, which requires a considerably lower voltage for its filament.

The constant-potential method of filament control is used rather than maintaining the constant rated current throughout the life of the tube. It is found that this method greatly prolongs the life of a tube, since the current is automatically reduced as the filament resistance increases because of disintegration. An alternating-current voltmeter is provided for this purpose which by means of a double-pole, three-way switch may be thrown upon either the rectifier tube bus or the power-tube bus or onto the speech-amplifier tube and the voltage adjusted by means of the respective rheostats. The plate current of the oscillator and modulator tubes and the speech-amplifier tubes are indicated separately by milliammeters and collectively by one meter which gives the total load on the rectifier tubes.



WIRING DIAGRAM OF 50-WATT ALTERNATING-CURRENT-OPERATED RADIOPHONE TRANSMITTING SET OF SAN JOAQUIN LIGHT & POWER CORPORATION

### Oscillatory Circuit Arranged for Long and Short Wave Work

In the oscillatory circuit are utilized two standard inductance coils of twenty-five turns each, two fixed-capacity 3,000-volt mica condensers of 0.002 mf. each, one variable mercury-mica condenser of 0.0012 mf. insulated for 4,000 volts, and one 5,000-ohm resistor which is used as a grid leak on the oscillator tube. One of the inductance coils is to be used as a loading coil for long-wave work, while the variable condenser is for short-wave work, either of which may be introduced into the counterpoise lead by the proper operation of a double-pole, double-throw switch. Another double-pole, double-throw switch is provided, which is used either to connect the antenna and counterpoise to the active inductance or to ground them both. Small choke coils of 1 henry reactance at audio frequencies are inserted in the grid circuit of the modulator tube and the plate circuit of the speech amplifier to prevent the dissipation of the audio-frequency impulses and practically forcing the effect of the speech amplifier upon the grid of the modulator tube. A radio-frequency choke coil is inserted in the plate lead of the oscillator tube to prevent the high-frequency output of that tube getting back into the other circuits. The output or plate circuit of the speech-amplifier tubes is capacitatively coupled to the grid of the modulator by means of a ½-mf., 1,750-volt condenser. Negative potential for the grids of the two tubes is supplied by small dry batteries, the values approximating 30 volts.

A three-winding modulation transformer is used, the secondary of which connects with the grid of the speech-amplifier tube. The primary winding connects with a receptacle on the panel for external connection to the speech-input circuit. The tertiary or third winding also connects to a receptacle so that the input may be monitored by plugging a telephone receiver in on it. The microphone system, which is external to the trans-

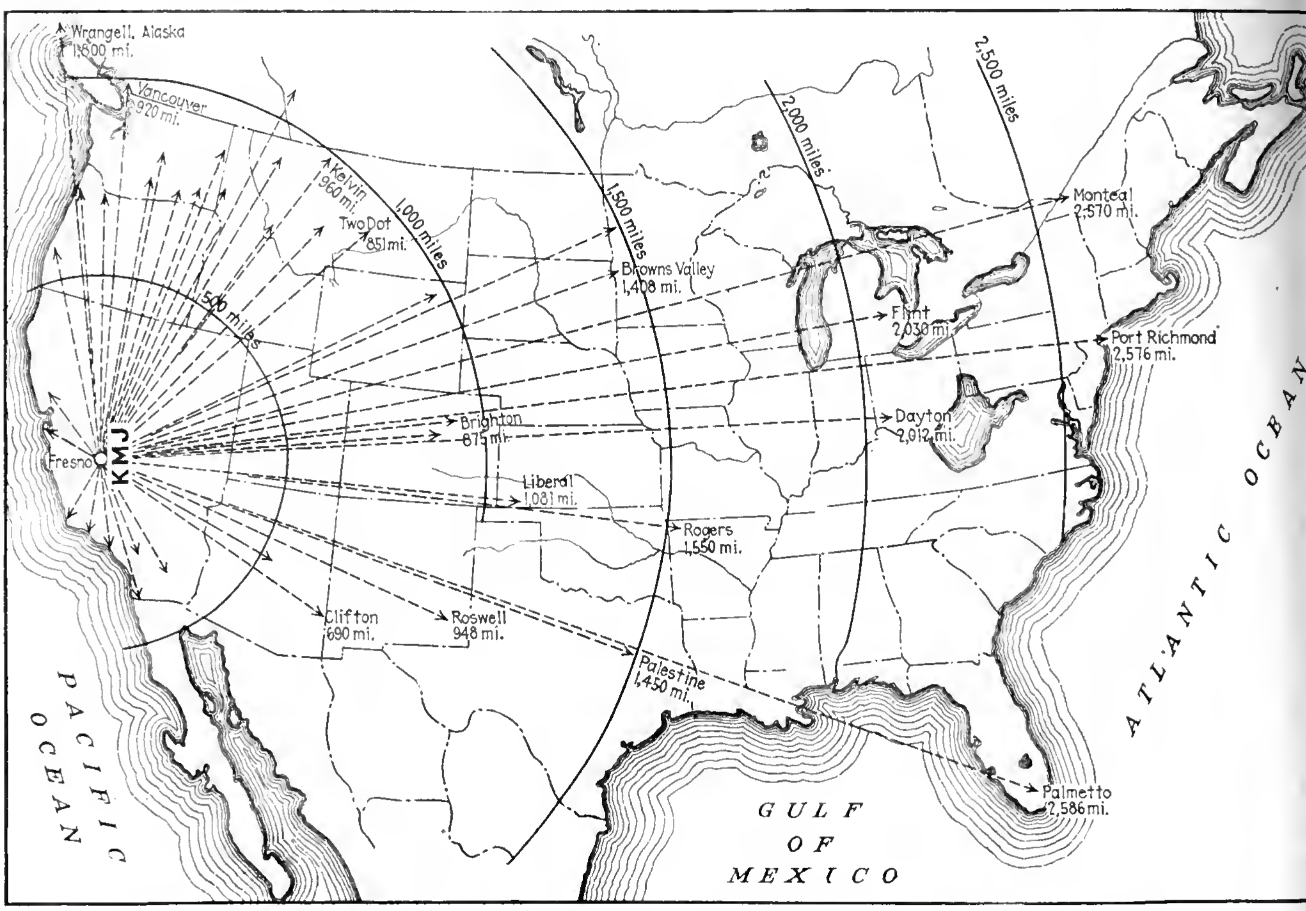
mitting set proper, consists of an induction coil with the center tap of the primary winding brought out for connection with the differential transmitter, which is a hand set used for announcing. The other transmitter is an especially sensitive device used for picking up vocal and instrumental music rendered in the studio. A four-point, double-throw telephone key switch serves to throw from one transmitter to the other, while the one battery and rheostat are used for both transmitters, the rheostat to control the volume.

The detailed description of the set may be followed with the aid of the wiring diagram reproduced. The set was designed by the writer and built up, switchboard style, in the shops of the company as illustrated in the accompanying front and interior photographs.

The fact that the set is principally used for broadcasting does not mean that it contains any special features except the pick-up transmitter, which does not materially add to the cost of the set. In fact, built of standard parts as it is, there is no reason why it cannot be duplicated by any power company having even meager shop facilities, at a total cost of $750. It may be built for even less, but hardly in such compact, shipshape form. It would be ill advised, however, to reduce the cost by eliminating any of the meters, as they are very essential to the proper adjustment of various circuits. Needless to say, the set may be used for carrier-wave transmission just as well as for radio, with certain additional apparatus for transferring the output to the lines.

Operating at normal power input rating, on a four-wire, flat-top T-type antenna 75 ft. high and 175 ft. long and a counterpoise of similar dimensions, this set has a normal radiation of 4 amp. at 360 m., which is indicated by a radio-frequency ammeter of the thermocouple type. Modulation, effected by speaking or whistling into the transmitter, produces from 0.2 amp. to 1 amp. variation in the radiation. This is known as the percentage modulation, and it is upon this that the voice range of the set depends to a large extent. It is possible to get a higher percentage modulation, but hardly without distortion.

Of the total number of reports on overland reception of speech and music from this set, 2 per cent were from stations more than 2,500 miles from Fresno, 1½ per cent between 2,500 and 2,000 miles, 2 per cent between 2,000 and 1,500 miles, 7 per cent between 1,500 and 1,000 miles, 51½ per cent between 1,000 and 500 miles and 37 per cent within 500 miles. Nearly every report pronounced modulation excellent and volume good. One person at a distance of 700 miles reported hearing ten consecutive concerts, which seems to prove the operation consistent. On several occasions conversations have been carried on by voice with Portland, Ore., a distance of 650 miles, and on one occasion with Denver, Colo., at 865 miles, the latter conversation being overheard in its entirety by a novice in Dayton, Ohio, 2,012 miles from Fresno. The remarkable thing about this record was that the novice used only a simple regenerative detector set without any amplification. These records were practically all made at 360 m. operation and subject to interference from a multitude of other stations broadcasting at the same or very nearly the same wave length.



LARGE PORTION OF UNITED STATES HEARS 50-WATT RADIOPHONE OF SAN JOAQUIN COMPANY AT FRESNO, CAL.
(Distance records obtained up to Feb. 23, 1923)

Therefore it is obvious that operating at much higher wave lengths, which would be the case in emergency operation as limited commercial stations, there would be virtually no interference and very consistent results would be had.

These records might seem to indicate that much more power than necessary was being used to cover the power system in question. Possibly so, but the power tube of the next smaller size has an output rating of only 5 watts, which is ostensibly not enough. Operating tubes in multiple to increase the output rating of a set is not particularly satisfactory without a complication of controls and meters, which immediately runs into expense. For such reasons it was considered inadvisable to experiment with less than a 50-watt tube; it was felt also that for operation through the summer months such capacity was not in any great excess for the service demand of the equipment.

### Continuity of Reception Largely a Matter of Training

Although it was not the intention that problems of reception should be within the scope of this article, the writer desires to remark that in his opinion the success of duplex operation of the radio telephone is going to hinge pretty much on the receiving end; but, after all, this is largely a matter of training the operating personnel. Broadcasting is having just that effect—not merely the San Joaquin corporation's efforts, but broadcasting in general is serving to acquaint the power man with receiving sets, getting him accustomed to the more or less delicate adjustments of the instruments. Numerous tests made about the San Joaquin system have well demonstrated the success of ordinary receiving sets employing one or two stages of audio-frequency amplification, connected with outdoor antennas. However, before duplex operation of the radiophone can be a complete success it will be necessary to resort to loop reception and radio-frequency amplification. This will permit stations transmitting at one wave length and, while transmitting, receiving at another wave length without interference from their own transmitter. This is the next problem to be attacked, now that much has been learned about radio-frequency amplification. A complete receiving set including a loud-speaking device should not cost more than $250, making a total investment of perhaps $1,000 for a complete two-way radio station.

## Making Water Work Upward

ARTESIAN wells are quite prevalent in the northern and middle parts of Florida, the necessary pressure evidently coming from some northern elevation, perhaps the Appalachians. It occurred to a local inventor with some vision that a water pressure upward is, as a source of power, just as good as the usual pressure downward. So he developed some small reaction turbines which could be mounted directly over an artesian well. They are made in sizes from 150 watts to 2,000 watts, directly connected to 32-volt or 110-volt direct-current generators. A storage battery is used with each outfit, and the main purpose of the generator is that of charging the battery continuously at a low rate.

The conditions are such that no centrifugal governor or electric regulator is necessary, and the outfit is exceedingly simple. Since an overflow is desirable, anyway, to keep an artesian well in a good condition, the farmer gets his light and power and still has his irrigation water. This method for producing power locally can be applied to advantage in several localities along the Gulf Coast where these artesian wells are found.

## Chemicals Produced by the Aid of Electricity

THE Department of Commerce announces that the reports made to the Bureau of the Census show a production of chemicals by processes involving the use of electricity of the value of $58,180,500 in 1921, as compared with $82,590,000 in 1919, a decrease of almost 30 per cent. In 1914 the value of chemicals produced by the aid of electricity was only $29,661,949. The increase, therefore, for the seven-year period, 1921-1914, was 96 per cent. The establishments reporting were 127 in number in 1921, 114 in 1919 and 36 in 1914. The principal products so produced, named in the order of value, are aluminum, the ferro-alloys, calcium carbide, chlorine bleaches (including chlorine and the hypochlorites), sodium hydroxide, the abrasives (including aluminous and siliceous), peroxide of hydrogen and oxygen. Many of these products serve as basic raw material for the production of a great variety of other chemicals.

Detailed statistics for 1921 and 1919 are given in the accompanying table. The statistics for 1921 are preliminary, and subject to such change and correction as may be necessary from a further examination of the original reports.

CHEMICALS PRODUCED WITH THE AID OF ELECTRICITY

| | 1921 | | 1919 | |
|---|---|---|---|---|
| | Quantity | Value | Quantity | Value |
| Chlorine Bleaches: | | | | |
| Chlorine (for sale), lb. | 36,211,000 | $1,955,900 | 34,392,000 | $1,425,917 |
| Hypochlorites, lb. | 168,774,000 | 4,509,500 | 252,850,000 | 4,781,348 |
| Hydrogen, cu. ft. | 92,757,000 | 639,600 | 137,082,000 | 851,397 |
| Oxygen, cu. ft. | 136,460,000 | 1,791,900 | 131,477,000 | 1,855,911 |
| Sodium hydroxide (for sale), lb. | 133,662,000 | 5,975,000 | 173,021,000 | 6,228,682 |
| Abrasives, aluminous and siliceous lb. | 23,533,000 | 5,500,300 | | |
| Bromine (for sale), lb. | 187,400 | 28,400 | | |
| Calcium carbide, net tons | 69,300 | 7,482,000 | | |
| Ferro-alloys, net tons | 48,500 | 8,835,400 | | |
| Halogen Derivatives (for sale): | | | | |
| Inorganic,[1] lb. | 10,217,500 | 214,100 | | |
| Organic,[2] lb. | 5,289,400 | 777,500 | | |
| Oxidized halogen compounds,[3] lb. | 5,136,500 | 410,800 | ........ | 67,446,750 |
| Peroxide of hydrogen, lb. | 27,296,000 | 2,157,600 | | |
| Peroxides and persalts,[4] lb. | 5,564,000 | 1,204,300 | | |
| Rare metals and alloys,[5] lb. | 1,078,000 | 1,289,400 | | |
| Metals n.e.s. (for sale),[6] lb. | 60,643,000 | 12,197,000 | | |
| Miscellaneous (for sale),[7] lb. | 35,624,000 | 3,211,800 | | |
| Total value | | $58,180,500 | | $82,590,005 |

[1]Hydrochloric acid, sulphur, zinc and iron chlorides, silicon tetrachloride, etc.
[2]Carbon tetrachloride, chloroform, iodoform, bromoform, ethyl chloride, etc.
[3]Sodium iodate, chlorate, bromate, etc.
[4]Peroxide of sodium, of barium, perchlorate of potassium, perborate of sodium, other peroxides, permanganates, persulphates, etc.
[5]Chromium, chromium-cobalt, magnesium, manganese, molybdenum, silicon, silico-manganese, tungsten, vanadium, etc.
[6]Aluminum, aluminum alloys, sodium, phosphorus and compounds.
[7]Sodium cyanide, carbon electrodes, carbon bisulphide, nitrites, oxalic acid, vanadic acid, hypophosphites, etc.

## Charging for Reactive Kva.-Hours and Active Kva.-Hours Separately

*To the Editors of the* ELEC RICAL WORLD:

The question is frequently raised: "Would it not be better to have the active component and reactive component of the kva. registered separately and have a different rate for each of them?"

Personally, I do not believe that public service commissions will ever allow such a charge to be made against customers. Public utilities must show costs in nearly every instance as a basis for the price of that which they sell. The cost of producing a reactive volt-ampere-hour is not in any way a fixed figure. For instance, a customer with a small load at 0.707 power factor would carry equal values of reactive kva.-hours and kilowatt-hours; a customer with a larger installation operating, say, at 95 per cent power factor might show the same value in reactive kva.-hours and hence pay the same price as paid by the customer with lower power factor. I do not believe any utility can show that a reactive volt-ampere-hour costs it a definite amount at any time, and certainly it does not represent any useful value to the customer, since the rating of electrical generating substations and distribution equipment is in volt-amperes.

However, a utility can show that with a certain volt-ampere demand a certain percentage of its capacity is tied up, and it can assign to this a definite value. The same is true if the bill is corrected by a power-factor clause which is properly worked out, although the power-factor clause complicates both the calculation of the customer's account and the metering of his load.

R. C. FRYER,
Superintendent Electric Meters.

Union Gas & Electric Company,
Cincinnati, Ohio.

## A Student's Viewpoint

*To the Editors of the* ELECTRICAL WORLD:

I should like to come to the defense of the instructor mentioned in a recent letter in the ELECTRICAL WORLD: "Where the College Instructor Falls Short." At present I am a student of electrical engineering and have had some practical experience in that work. The average man who expects to matriculate into a technical profession realizes that the work given by colleges is very theoretical and that these principles must be applied to the methods and peculiar business conditions of the company which he represents before he can hope for gratifying results. Admitting the large amount of discussion raised by the issue of practical versus theoretical instruction, I believe that for the average student the instructor who can teach the principles involved is more valuable than the man who has had the practical experience but cannot get his ideas across to the student.

A man must obtain his knowledge of the fundamental principles in college if he is to gain a working knowledge of the subject. The practical application can be learned in the business world by actual contact. For this reason, if one of the two must be sacrificed, it is much better to give up the practical side while in school. Most technical schools require a certain amount of practical work and a satisfactory report on it. The student receives more benefit from his personal contact with business than from the practical instructor. It would be an ideal condition, one for which we can hardly hope, if the instructor had had valuable practical experience and was also able to present his subject efficiently to a group of students. Such men are at a premium in the industrial world.

As a student I feel that colleges are sources of knowledge of the principles which we need in our chosen line. It is a question of first getting equipped and then using this equipment most advantageously.

EMMET G. GARDNER.

Ohio State University,
Columbus, Ohio.

## Report on Post Office Illumination Criticised

*To the Editors of the* ELECTRICAL WORLD:

I read with much interest the article entitled "Illumination of Post Offices" published in the March 24 issue of the ELECTRICAL WORLD. I also have a copy of the bulletin issued by the Post Office Department, which I understand from the Office of Industrial Hygiene of the United States Public Health Service is a preliminary report issued by it to the Post Office Department covering work which it has completed on the New York Post Office. I should like to comment on the article appearing in the ELECTRICAL WORLD on this subject as follows:

The specifications for the luminaires for the general workrooms and for the offices is to my mind a very poor one. In the first place, there is no authority for the limitation of brightness at any point not to exceed 2½ cp. per square inch when used with a 200-watt lamp. The flux percentages in the various zones called for in the specification describe very inefficient units of the diffusing type as almost any unit of poor quality could conform to the specifications.

The specifications also state that at least 28 per cent of the bare lamp flux should be emitted in the 0-60-deg. zone and at least 48 per cent in the 0-90-deg. zone, which in substance means that there should be at least 20 per cent of the bare lamp flux emitted in the 0-60-deg. zone. It is a well-demonstrated fact that the light flux in the 60-90-deg. zone is undesirable as it is a cause of glare. In view of this it is evident that the light flux should be limited in the 60-90-deg. zone and that, instead of specifying at least 20 per cent in this zone, the specification should read "not more than — per cent in this zone."

I also note that the luminaires should be in such number and so spaced that the brightness of the units measured in lumens per square foot would not be more than one hundred times as great as the intensity of illumination measured in foot-candles. The number of luminaires used and their spacing would have little effect on the proportion-brightness divided by foot-candles. Furthermore, there is no authority for the figure 100 representing this proportion.

The vertical plane in post office work is quite as important as the horizontal plane. This has not been sufficiently taken into account inasmuch as the specifications for the general workroom and office luminaires

do not include any specific data which would specify illumination on vertical surfaces approximating the illumination on the horizontal surfaces. In fact, luminaires conforming to the specifications would produce illumination intensities on vertical surfaces of approximately one-half those produced on horizontal surfaces.

Regarding the paragraph relating to glare and surface brightness, there are six elements of glare listed and the total flux of light in the angles of 60-90 deg., which is a very important glare factor, has been totally omitted.

If glare is defined as the decrease in the ability of the eye to define objects, there are important data on record which indicate that the brightness of the light source is of little practical effect in producing glare and that the total flux of light which enters the eye is the important factor. Moreover, it has been found that the glare increases as the angle at which this flux enters the eye approaches 90 deg.

The paragraph defining direct, semi-direct, semi-indirect and indirect lighting is very much out of date. At the 1922 convention of the Illuminating Engineering Society Dr. Luckiesh presented a paper on this subject which indicated the common-sense way of defining luminaires as regards their direct and indirect components, and the data given in this paper should by all means be used in any recent literature on the subject.

It is to be hoped that the authors of the "Illumination of Post Offices" will give further thought and study to the subject before issuing their final recommendations as it is customary for the layman to regard data given out from the United States government departments as authoritative, which it should be.

DAVIS H. TUCK,
Electrical Engineer.
Holophane Glass Company, Engineering Department,
New York, N. Y.

## The Specifications for Overhead Lines

*To the Editors of the* ELECTRICAL WORLD:

In the editorial "The Specifications of 1914 are Retired" (page 616 of the March 17 issue of the ELECTRICAL WORLD) are some statements and inferences not quite in accordance with the facts, or at least with certain understandings as to the program to be pursued. It would be unfortunate if the ELECTRICAL WORLD were to cause further misunderstandings of this unhappy subject.

Without going into ancient history as to joint specifications that did not stay "joint," it would be fairer to admit that some rather important interests have never accepted the code as a specification. The status at present is that the code was adopted as an American standard provided that it was to be at once revised by a joint body or sectional committee and, further, that after such revision that body should prepare a specification for crossings. There has been some criticism that it was unusual to adopt an engineering rule subject to an unmade revision, but it has been expected and promised that there would be no attempt to rush the general adoption of the present code as a crossing specification. In the view of the writer it is well to allow the matter to rest, without propaganda from either side and without the adoption by regulatory bodies of any specification, until our sectional committee has had a fair chance to agree on something.

## Easy Solutions to Hyperbolic Functions

*To the Editors of the* ELECTRICAL WORLD:

In view of the growing importance of hyperbolic functions in electrical engineering and the somewhat meager, or at least inaccessible, published information in regard to the computation of the inverse functions, it would seem that material of this kind is of sufficient general interest to warrant publication.

The material is not particularly new, but I have never seen the formulas in this form and believe that they are suitable for presentation in your columns. They were derived by means of Euler's exponential expressions for the sine and cosine, and apply for all values of $u$ and $v$, positive, negative and imaginary.

The last three expressions can be derived in order from the first three by using the reciprocal of $u + jv$ in place of $u + jv$ itself.

The results are:

$$x + jy = \sinh^{-1}(u + jv) = \log_\epsilon[u + jv \pm \sqrt{1 + (u + jv)^2}].$$

$$x + jy = \cosh^{-1}(u + jv) = \log_\epsilon[u + jv \pm \sqrt{(u + jv)^2 - 1}].$$

$$x + jy = \tanh^{-1}(u + jv) = \frac{1}{2}\log_\epsilon\left[\frac{(1 + u) + jv}{(1 - u) - jv}\right].$$

$$x + jy = \operatorname{cosech}^{-1}(u + jv) = \log_\epsilon\left[\frac{1 \pm \sqrt{(u + jv)^2 + 1}}{u + jv}\right].$$

$$x + jy = \operatorname{sech}^{-1}(u + jv) = \log_\epsilon\left[\frac{1 \pm \sqrt{1 - (u + jv)^2}}{u + jv}\right].$$

$$x + jy = \coth^{-1}(u + jv) = \frac{1}{2}\log_\epsilon\left[\frac{(1 + u) + jv}{(u - 1) + jv}\right].$$

For numerical work the third and sixth expressions are particularly convenient. They must, of course, be evaluated by the methods usual in vector work. The positive value of the double sign is used in connection with the others.

As an illustration take the following example:

$$\begin{aligned}
\tanh^{-1}(1.315 + j0.608) &= 0.5 \log_\epsilon \frac{(1 + 1.315) + j0.608}{(1 - 1.315) - j0.608} \\
&= 0.5 \log_\epsilon \frac{2.315 + j0.608}{-0.315 - j0.608} \\
&= 0.5 \log_\epsilon \frac{2.39 \;/\underline{14^\circ 43'}}{0.685/\underline{117^\circ 23'}} \\
&= 0.5 \log_\epsilon 3.49/\underline{132^\circ 6'} \\
&= 0.5 \log_\epsilon 3.49/\underline{2.30} \\
&= 0.5\,(\log_\epsilon 3.49 + j2.30) \\
&= 0.625 + j1.15.
\end{aligned}$$

Thus:

$$x = 0.625, \quad y = 1.15.$$

Work of this kind is facilitated a great deal by use of a slide rule with a set of scales graduated so that a vector quantity can be transferred quickly from polar to rectangular co-ordinates and vice versa. A number of such rules have been constructed by a leading manufacturer and are quite successful. Such slide rules would be useful also in mechanical engineering and in bridge-design work.

# Central Station and Industrial Practice

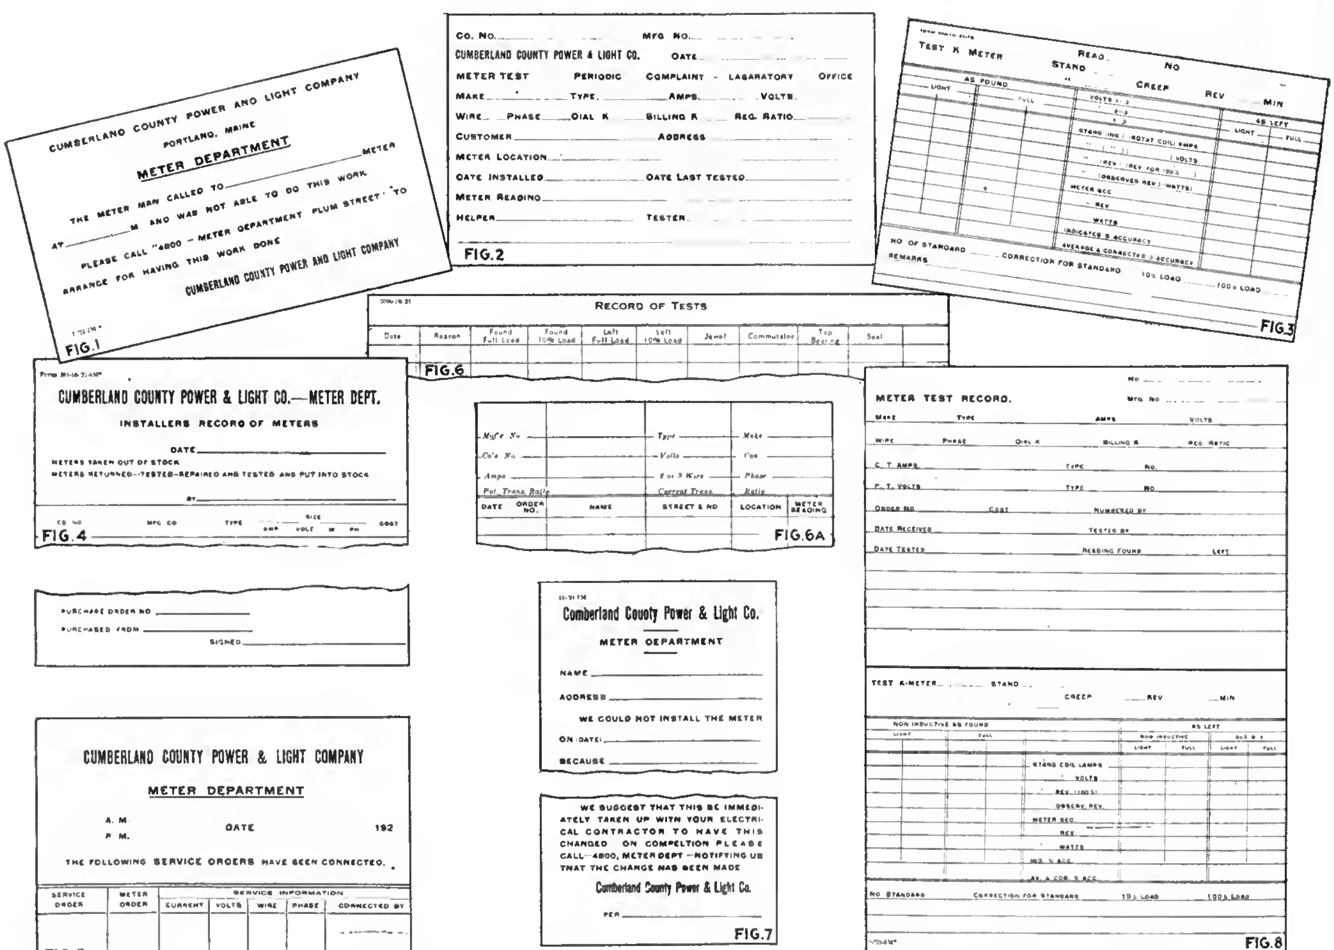
Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants

## Meter Testing in Maine

METER tests on the system of the Cumberland County Power & Light Company, Portland, Me., include shop tests, periodic and complaint tests. In the first class are included tests on new meters, tests on meters returned from customers' premises and tests on repaired meters. Periodic tests are made on customers' premises according to service requirements, and these include an inspection of the installation with reference to proper metering, the working condition of the meter, connected load and general conditions. This test helps the company's public relations, inasmuch as courteous meter testers afford evidence that the company checks its meters regularly and helps allay the idea that all meters are set fast. Complaint tests are made to remove a customer's suspicions, and these are helpful in securing better conditions on the premises.

At Portland the company has a standardizing set going back to the standard cell by which an indicating laboratory wattmeter is calibrated. Against this wattmeter is calibrated in turn another rotating standard. Using this rotating standard as a laboratory standard, we are able to check our portable rotating standards whenever conditions do not work just right, or else periodically once every week. This laboratory rotating standard is checked every three months to make sure that no conditions have changed it. All calibrations, and especially when the laboratory rotating standard is used, are done by qualified men, and every precaution is taken to prevent overloads or damage to the rotating standard. In this way we feel perfectly safe regarding our standards.

*Meter Testing.*—With reference to meter testing, tests are conducted on single-phase, two-wire meters, single-phase, three-wire meters and polyphase meters. The actual test-



TYPICAL FORMS EMPLOYED BY ONE COMPANY FOR KEEPING ITS METER RECORDS

Figs. 2 and 3—Subsequent test record. Fig. 3 printed on back of Fig. 2.
Fig. 4—Form used as a check of meters taken out or returned by meter installers.
Fig. 5—Record of services as reported by service department.
Figs. 6 and 6A—Meter record card. Gives the complete history of the meter. Fig. 6A printed on back of Fig. 6.
Fig. 7—Form used when wiring is defective or rules have not been followed.
Fig. 8—Original record of shop tests.

ing on all meters is the same. The tester always notes the general condition of the meter and its surroundings, especially meter seals and evidences of tampering. He checks coils, bearings, rusting of the meter, the position of the magnets, the position of light-load adjustment, creeping and anything wrong that should be corrected. The single-phase two-wire and three-wire meters are used on house service and are tested non-inductively, although with the type of appliances that is beginning to be used by houses it may be well to have the power-factor adjustment within 4 per cent. Where a single-phase meter, however, is used for power, as on single-phase motors, just as much care should be used on the power-factor adjustment of this meter as on a polyphase meter. In our own case the 220-volt, two-wire meters used for this purpose are adjusted for power factor.

In the polyphase meter we have a different condition and the method of testing has to be well looked into. All polyphase meters are tested with coils in series. To check correctness in doing this a series of tests were run of a polyphase meter on polyphase load against two single-phase rotating standards. These tests proved that the meter on polyphase load has the same accuracy as the meter with coils connected in series. Testing each element separately is liable to make the meter fast. The routine of testing a polyphase meter is as follows:

ROUTINE TESTING OF METERS

The potential coils are connected in parallel and the current coils in series but bucking so as to make one element rotate backward. The electric elements are moved in or out from the shaft till no tendency to rotate is apparent. The meter is then reconnected, coils in series, and adjusted for 100 per cent non-inductive load.

*Power-Factor Test.*—Leaving the meter as connected for the unity-power-factor test and throwing the potential on the other phase will immediately give a power-factor test. If the meter is found off, each element is tested separately to see where the error lies. This element is then adjusted to bring the power-factor accuracy to 100 per cent, after which the meter is rechecked with the coils in series.

The question of power factor is becoming of primary importance, and a discussion as to various methods of power-factor tests and as to what should be done with reference to power factor would be of value. Another method is, instead of checking power factor at 50 per cent, to check a meter as low as 20 per cent or 30 per cent power factor.

On alternating-current meters the light-load test should be made around 5 per cent load. This is done to prevent creeping. Alternating-current meters have a very rapid percentage accuracy curve upward with decreased load, and should a meter be set accurate at 10 per cent load it may creep, owing to the high overcompensation. Full load should be taken at points above 75 per cent load.

*Meter Records.* — For keeping records of meter tests we have a general system of folders and test cards. These folders contain all data on the meters together with the original shop test. As subsequent tests are then made on the same meter these tests are recorded either on a stiff card for outside tests or on the light-weight form for shop tests. Every test made on a certain meter is put into this folder, giving a complete record of all work done on that particular meter.

The tests are also recorded on the meter record so that by taking out this card the various periods of tests, together with the accuracy found, can be used to determine how often this meter should be tested. The meter-record cards have various colors which designate the type of installation, giving an idea of the importance of the meter. These colors are as follows: White — 5-amp. watt-hour meters, single-phase; red — alternating-current single-phase meters from 10 amp. up and self-contained and alternating-current polyphase meters; blue—meters either used with current or potential transformers or both; buff—direct-current meters.

Meter Department.
Cumberland County Power & Light Company,
Portland, Me.

# Extracts from an Operating Code

BY FIELD EDITOR ELECTRICAL WORLD
New York, N. Y.

## Induced-Draft Fans

WHEN starting forced-draft fans, the stack draft damper should be closed to enable the fan to start under minimum load and also to enable the boiler operator to make proper adjustments more readily than if the dampers were left open. The following instructions, as abstracted from the operating code of the Philadelphia Electric Company, pertain to starting and shutting down induced-draft fans:

STARTING

1. See that the stack damper is closed.
2. Turn on the cooling water to the bearings.
3. Start the turbine or motor.
4. See that the oil rings are operating and supplying oil to the bearings.
5. Bring the unit up to speed.
6. Inspect the unit for excessive vibration and, if excessive vibration is discovered, report the trouble to the shift superintendent.
7. If the main oil switch (controlled at the boiler operating boards) should trip, have an inspection made by the electrical mechanic and any trouble corrected before closing it again.

SHUTTING DOWN

1. Shut down the turbine or motor.
2. Shut off the cooling water from the bearings.
3. Close the induced-draft dampers (or bypass the induced-draft fan).

## Testing Overspeed Devices

TESTING overspeed devices on rotary converters and motor-generators should be done under the direct supervision of the substation supervisor or foreman, according to the operating code of the Philadelphia Electric Company. This test can only be made when the machines being tested are running in parallel with another source of direct current.

The following instructions for testing overspeed devices as abstracted from the operating code referred to above should prove of value to any one making these tests:

1. Disconnect or block the reverse-current trip.
2. Adjust the field rheostat so that the speed will remain close to normal (about unity power factor or slightly leading); open the oil switch, leaving the direct-current switches and circuit breakers closed and the neutral switch open.
3. Cut in the field resistance slowly, observing the speed of the machine with a tachometer, until the overspeed device opens the circuit breakers (not exceeding 15 per cent above normal speed).
4. Observe the speed at which the overspeed device operates; this speed should be about 10 per cent above normal.
5. If the device does not operate at this speed, make adjustments and repeat the test.

## Signposts of Steam Plant Economy

WITH the advent of boilers built to operate on 650 lb. pressure and corresponding advances in the design of prime-mover equipment, expected total plant efficiencies will closely approach the record of the Diesel engine. This statement was made by E. F. English, chief engineer General Engineering & Management Corporation, New York, at a recent meeting of utility managers of the organization. Boilers are now being installed to operate at 525 lb., and today turbo-plants are operating at 350 lb. and more than 700 deg. steam temperature. Plants are now operating on powdered coal at monthly boiler efficiencies of 82 to 84 per cent. The speaker held that within ten or fifteen years all coal under the larger boiler plants will be burned in powdered form. The supply of fuel oil is relatively limited, known deposits embracing only fifty years' requirements against several hundred years' coal resources.

TABLE I—HEAT LOSSES IN AN AVERAGE BOILER ROOM

| How Lost | Per Cent of Heat in Coal |
|---|---|
| 1. Handling at plant | 1 0 |
| 2. In ash | 3 9 |
| 3. By radiation | 2 9 |
| 4. By incomplete combustion | 0.7 |
| 5. On account of air leakage in furnace and boiler | 9 8 |
| 6. On account of excess air through gates | 9.8 |
| 7. Because of short-circuiting of gases in gas passages of boiler | 1.1 |
| 8. From soot on heating surface | 3.9 |
| 9. From scale in boiler | 5 0 |
| 10. Because of incorrect amount draft for load | 3 8 |
| 11. Because of leakage of water and steam | 0.7 |
| Total preventable or reducible losses | 42 6 |

The preventable losses in boiler plants of average rating are shown in Table I. These preventable losses are seldom below 25 per cent in medium-sized boiler plants. Important gains in economy in late years have resulted from the use of higher settings. In the speaker's practice, the front header is set from 10 ft. to 15 ft. above the floor. Tight furnace walls, unwarped baffles, unburned baffles and tubes free from soot are essential to efficient operation. Inadequate draft has caused poor efficiency in many cases, although excess air beyond combustion necessities is even worse. The losses resulting from excess air for combustion are shown in Table II. Scale in tubes is also a source of waste, ⅛-in. scale causing a loss of 12 per cent in heat transmission.

TABLE II—RELATION BETWEEN EXCESS AIR, $CO_2$ AND FURNACE TEMPERATURE

| Per Cent of $CO_2$ in Flue Gas | Pounds of Air per Pound of Fuel | Fire Temperature, Deg. F. | Approximate Percentage of Excess Air | Fuel Tonnage, Per Cent |
|---|---|---|---|---|
| 20 | 12 | 3,910 | 9 | 11 |
| 16 | 15 | 3,190 | 36 | 12.5 |
| 13.4 | 18 | 2,700 | 64 | 15 |
| 11.4 | 21 | 2,340 | 91 | 17.5 |
| 10 | 24 | 2,060 | 118 | 20 |
| 8.9 | 27 | 1,850 | 146 | 22.5 |
| 8 | 30 | 1,680 | 173 | 25 |
| 7.3 | 33 | 1,535 | 200 | 27.5 |
| 6.7 | 36 | 1,415 | 227 | 30 |
| 6.2 | 39 | 1,315 | 254 | 32.5 |
| 5.8 | 42 | 1,225 | 282 | 35 |
| 5.0 | 48 | 1,085 | 336 | 40 |

The chief item entering into the cost of power production is fuel. It is probable that the boiler-room foreman can save or waste more money than any other man in the plant organization. Cheap labor in the boiler room is the most expensive help available. Table III shows the proportion of fuel costs to total in a group of seven plants.

Care in fuel selection from the standpoint of heat content per unit of cost, the use of adequate indicating and recording instruments, attention to vacuum and feed-water heating, all are needed in the campaign for plant efficiency. The heat in a pound of coal from various mines may vary as much as 100 per cent, against a maximum of 8 per cent in fuel oil over a wide range of gravity. Roughly, 1 per cent of fuel is saved for each 11-deg. increase in feed-water temperature. The variation of an inch in vacuum at the exhaust end of a modern steam turbine may change the water rate by 1 lb. Boiler-feed pumps should have at least 10-ft. head on the hot-water suction inlet, and the formation of scale or sludge in condenser tubes seriously impairs heat transmission and should be checked by inspection and temperature records.

### Instruments and Records

Instruments for boiler and engine room operation have been sadly neglected till quite recently, and even now a large amount of steam is generated with the aid of no other instruments than a steam gage and gage glass. The instruments which tend to give us a strong grasp on varying conditions are really signposts on the road to economy, and when properly used are worth-while investments.

Among these most deserving of installation are a draft gage connected so as to read furnace, ash-pit and uptake pressures and the drop through the boiler; a pyrometer to read flue-gas temperatures, one instrument being so connected as to serve a number of boilers; the $CO_2$ recorder or, where expense prevents, an Orsat; a thermometer in the feed line, some method of determining the weight of coal and ash, and a steam-flow meter is also desirable.

By the use of the indicator varying conditions in engine operation can be detected and corrections made. The vacuum gage, preferably a mercury column, and thermometers for indicating the inlet and discharge temperatures of the condenser circulating water are of great assistance in the efficient operation of the condenser and its auxiliaries.

Only useful records should be kept. Some operators require power-plant employees to keep many records, most of which are filed away and never consulted afterward. The chart form is much better than a column of figures in emphasizing changes in conditions. It is of primary importance that an accurate record should be kept of output and fuel. A continuous record of fuel burned, water evaporated and output is of far greater value in showing production costs and condition of equipment than any spasmodic tests of apparatus no matter how thorough. Important boiler-room records con-

TABLE III—ELEMENTS OF PRODUCTION COST IN PERCENTAGE OF TOTAL

Plants Nos. 1, 3 and 5 are oil-burning and have 705,570, 1,604,430 and 1,710,410 kw.-hr. yearly output respectively. Plants Nos. 2, 4 and 6 are coal-burning and have 681,230, 2,208,220 and 4,347,400 kw.-hr. yearly output respectively. Plant No. 7 gives an average type of large-power-plant operation with an approximate average yearly output of 79,000,000 kw.-hr. The figures are for the twelve months ended Dec. 31, 1922.

| Plant: | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|
| Fuel | 51.2 | 61.8 | 67.9 | 68.7 | 70.4 | 75.0 | 69 |
| Labor | 29.5 | 18.8 | 11.0 | 19.4 | 17.9 | 17.4 | 18 |
| Maintenance | 15.8 | 14.3 | 17.3 | 6.7 | 8.1 | 3.5 | 9 |
| Miscellaneous | 3.5 | 5.1 | 3.8 | 5.2 | 3.6 | 4.1 | 4 |
| Total | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |

cern quantity and temperature of feed water, boiler pressure, draft and temperature of gases leaving boiler; time of cutting in and cutting out boilers, and when and how long boilers were blown down. Important engine-room records are on load carried, vacuum, temperature of circulating water entering and leaving condenser, and hot-well temperature. Time of starting and stopping units should also be recorded.

Much of the foregoing, in a general way, applies also to Diesel plants, gas plants and ice plants.

The Diesel engine requires careful maintenance and attention to details. In general, after a certain time has elapsed, inspection should be made to see whether attention is required, and at intermediate times, if there is any indication of the improper functioning of any part, investigation should be made and such maintenance work as is necessary done. For proper maintenance a chart should be made up on which are listed all parts of the engine that require attention, and for each item an estimate should be made as to how often it should be inspected. Notes should also be made of the condition on previous inspection. Of course, the lubricating and cooling system requires constant supervision. As one manufacturer has said, "The lubricating system is the heart of the Diesel engine."

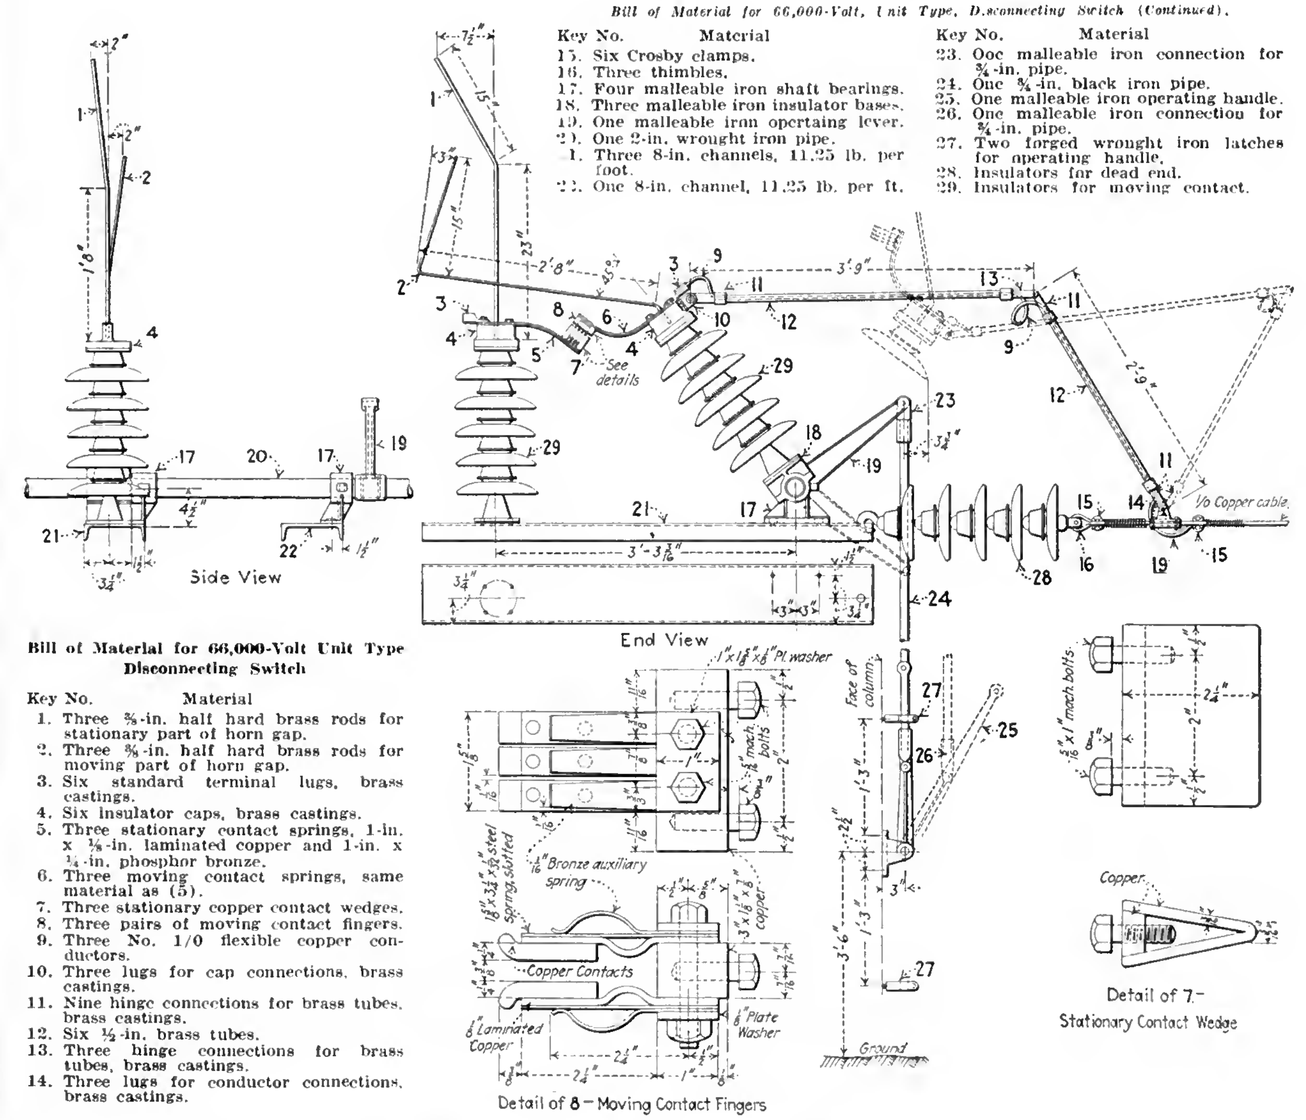
## Tennessee Company's New "Disconnect"

WHEN poles settle, most of the disconnecting switches which the Tennessee Electric Power Company has used up to this time tend to get out of alignment. Furthermore, most of these switches require four poles and more than two insulators per phase. To eliminate these and other objections the company has developed the rocking type of "disconnect" shown, which requires only two poles for mounting and which has the advantage of not getting out of alignment easily.

It may be observed that one insulator per phase is fixed and supports one end of the line, a stationary contact and an arcing horn. The other insulator rocks about a horizontal axis, carrying with it the movable contact and an arcing horn. Connecting it with the other terminal of the line is a jack-knifing tube which contains a flexible lead, this being hinged at both ends and the middle.

E. C. WILLIAMSON,
Electrical Engineer.
Tennessee Electric Power Company,
Chattanooga, Tenn.



**Bill of Material for 66,000-Volt Unit Type Disconnecting Switch**

Key No. Material

1. Three ⅜-in. half hard brass rods for stationary part of horn gap.
2. Three ⅜-in. half hard brass rods for moving part of horn gap.
3. Six standard terminal lugs, brass castings.
4. Six insulator caps, brass castings.
5. Three stationary contact springs, 1-in. x ⅛-in. laminated copper and 1-in. x ¼-in. phosphor bronze.
6. Three moving contact springs, same material as (5).
7. Three stationary copper contact wedges.
8. Three pairs of moving contact fingers.
9. Three No. 1/0 flexible copper conductors.
10. Three lugs for cap connections, brass castings.
11. Nine hinge connections for brass tubes, brass castings.
12. Six ½-in. brass tubes.
13. Three hinge connections for brass tubes, brass castings.
14. Three lugs for conductor connections, brass castings.

*Bill of Material for 66,000-Volt, Unit Type, Disconnecting Switch (Continued).*

Key No. Material

15. Six Crosby clamps.
16. Three thimbles.
17. Four malleable iron shaft bearings.
18. Three malleable iron insulator bases.
19. One malleable iron opertaing lever.
20. One 2-in. wrought iron pipe.
21. Three 8-in. channels, 11.25 lb. per foot.
22. One 8-in. channel, 11.25 lb. per ft.
23. One malleable iron connection for ¾-in. pipe.
24. One ¾-in. black iron pipe.
25. One malleable iron operating handle.
26. One malleable iron connection for ¾-in. pipe.
27. Two forged wrought iron latches for operating handle.
28. Insulators for dead end.
29. Insulators for moving contact.

ROCKING-TYPE "DISCONNECT" DEVELOPED BY TENNESSEE COMPANY FOR 66,000-VOLT LINES

## Strength of Wood Poles Not Affected by Perforating

THAT the exact loss of strength due to the perforation of wood poles to insure better penetration of the preservative oils is not of sufficient importance to justify the making of strength tests unless an unusual opportunity arises is the conclusion of a committee of the American Wood Preservers' Association, which presented a report at a recent convention in New Orleans. The committee said that theoretical loss of strength had been determined as being a function of the depth of the holes and the maximum percentage of the circumference cut in a horizontal plane, and it was of opinion that the recognition of this principle gives the essential information and that the only value of making strength tests is to check the actual and theoretical strength losses. The committee is expected to continue consideration of the subject, making tests if the proper opportunity offers.

The committee also asserted that no improvement in the perforating patterns now in use can be made until greater knowledge is gained as to seasoning and its effect or that of other unknown factors upon the oil travel. No conclusion was reported on the study of the committee to determine the effect of seasoning on penetration and whether it would be possible to classify poles as to condition of seasoning and then find a way quickly and accurately to identify such classifications.

The committee's study showed that the effect of the perforated treatment is to prevent harmful checking and to a marked degree to close checks which are in the timber at the time of treating. The non-perforation treatment does not prevent checking in green timber, but lessens the checking in partially seasoned or seasoned timber. The report further said that perforation without the treatment lessens checking to a greater extent than the non-perforation treatment. The experiments on which the conclusions were based were carried on at St. Paul, and the committee thought that results in other latitudes might vary. An investigation of the records of representative pole lines with perforated and unperforated poles is being made.

The committee on pressure treatments continued its work in the examination of the life history of full-cell process-treated poles and submitted some tentative full and empty process-treatment specifications and also information on empty-cell treated pole lines in Europe. Hundreds of thousands of poles are reported to have been treated by this process and erected in England with no cases of failure as yet brought to the attention of telephone and telegraph officials.

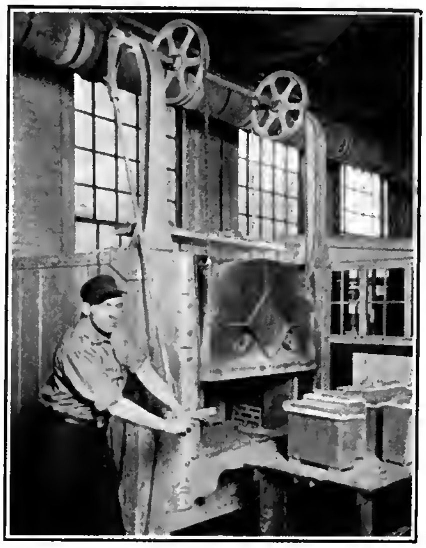
## Small Parts Heat Treated Electrically for 0.33 Cent per Pound

RECENTLY the engineers of the Royal Typewriter Company, Inc., Hartford, Conn., were confronted with the problem of producing slide rails for their product which would withstand indefinite wear. These pieces are of such shape that ordinary methods of carburizing, such as coal-fired or gas-fired furnaces, were unsuccessful owing to the distortion from uneven heating. After a study



NOT A SINGLE FAULTY HEAT TREATMENT HAS OCCURRED IN FIRST HALF YEAR'S OPERATION OF THIS FURNACE

of the available apparatus a Hagan electric furnace was installed, and this has operated for more than six months without the discovery of a single faulty heat treatment.

The furnace specifications called for the following service:

Heat treatment: Case hardening.
Material to be hardened: Drop-forged steel, 10-point to 20-point carbon.
Estimated weight of pieces per heat: 225 lb.
Estimated weight of containers per heat: 775 lb.
Estimated weight of compound: 90 lb.
Total weight of parts to be case-hardened per week of fifty hours: 3,750 lb.
Dimensions of containers, approximate: 15 in. x 7 in. x 12 in. deep, outside.
Electrical supply available: 220-volt, 60-cycle, two-phase energy.
Furnace temperature required: 1,650 deg. F.

To meet these requirements the furnace built has a working chamber 4 ft. 10½ in. long x 3 ft. wide x 1 ft. 11 in. high and a connected load of 60 kw. The insulating walls are 9 in. thick and the door specially insulated. A view of the furnace is shown herewith. Leeds & Northrup full automatic control was utilized, and the thermocouple is mounted directly above the work in the front center of the furnace. Alloy pots are used.

Five to six hours are required for the furnace to attain its operating temperature of 1,650 deg. F. when starting cold. The work is then placed in the furnace and the temperature falls to about 1,100 deg. F. After this about one and a half hours is required to bring the charge up to 1,650 deg. F. A six-hour bake produces the desired penetration of thirty to forty thousandths of an inch. To every rail is given a Rockwell hardness test.

A production of fifteen heats per week is the regular schedule. This consists of: Work, 2,475 lb.; charge, 3,300 lb.; pots, 11,940 lb.; total, 17,715 lb. The total consumption of electricity for a week's run is 3,500 kw.-hr. The cost per pound of actual work done is 2.38 cents, or 0.33 cent per pound of total charge.

Temperature readings show that the furnace walls average only about 150 deg. F. except around the door and at the point where the leading-in cables enter the furnace walls. The radiation loss is about 6 kw. A rough comparison with a coal-fired furnace having two compartments 2 ft. wide x 5 ft. long showed that the fuel expense was slightly less than the electrical cost, but the cost of handling coal and ashes brought the total cost per pound of work carburized about to the level of the electrical cost. With electric heating there is no guesswork as to temperature conditions on the part of the operator and high quality is assured.

H. W. DERRY,
Power Engineer.
Hartford Electric Light Company,
Hartford, Conn.

# Central Station Business

**Commercial Organization and Management, Customer and Trade Relations, Public and Financial Policies, and Reports of Company Plans and Experiences**

## A Survey of the Appliance Load*

### Investigation of Three Groups of 270 Residences in Chicago Indicates that Household Devices Account for Approximately 20 per Cent of Energy Used in Homes

BY H. B. GEAR

Commonwealth Edison Company, Chicago

THE use of household appliances has for some years been encouraged by central-station men who have seen in such devices a means of increasing the revenue derived from the residence customer. To determine just what this business meant to the company in energy consumption and revenue the Commonwealth Edison Company recently made a survey of a number of typical residences of various classes.

#### PLAN OF THE SURVEY

The customers chosen were selected to form three groups of about 270 each, classified as "above medium," "medium" and "below medium." The "medium" group was selected on the basis of the average kilowatt-hour consumption per year of all residence customers and on the general character of buildings as regards rental values. This group consisted of 119 houses and 158 apartments whose average annual consumption was 367 kw.-hr. The "above medium" group consisted of 75 houses and 147 apartments with an annual consumption of 525 kw.-hr. The "below medium" group included 85 houses and 229 apartments, with an annual consumption of 216 kw.-hr. Each of these 813 customers was interviewed by two census takers, one to inspect lamp and appliance ratings and one to fill out a very complete record sheet.

The customers were selected in groups supplied by a separate transformer installation. Curve-drawing meters were used to get from each such transformer the load records of the group for seven consecutive days. In order to obtain data as to energy consumption of different appliances, records were taken of six to eight of each group for seven days from a meter set on the premises. The co-operation of customers was readily obtained by presenting them with an electrical appliance to compensate for their trouble.

The number and general characteristics of the residences surveyed are given in Table I. It will be seen that there are considerable differences between the various classes as regards the size of the residence, the number of persons in the family and the energy consumption. It is of interest to note that the connected load in appliances exceeds that in lamps in most cases.

The data from the census of appliances are presented in Table II The number of appliances per 100 residences is indicative of the degree of saturation reached with the various devices. The flatiron is easily the leader, as it constitutes about 40 per cent of the total number of appliances found, the vacuum cleaner and toaster being next in order, with 18 per cent and 13 per cent respectively. The washing machine is 8 per cent, the percolator 6 per cent and all other devices are 14 per cent of the total found. Two thousand and five appliances were found in 813 houses, or 2.4 per residence. The washing machine is not as generally found in apartments as in houses, and this is true to a less extent with vacuum cleaners, but the reverse is true with the toaster.

From the test charts the hourly kilowatt-hour consumption by lamps and appliances was determined and the consumption of the various ap-

TABLE II—CENSUS OF APPLIANCES

TABLE III—COMPARISON OF ESTIMATED AND COMPUTED CONSUMPTION

| | Annual Kw.-Hr. Used by Appliances | |
|---|---|---|
| | Estimated | Test Week $\times$ 50 |
| **Flatirons:** | | |
| Houses | 63 | 94.2 |
| Apartments | 48.5 | 69.7 |
| **Vacuum cleaners:** | | |
| Houses | 6.2 | 7.8 |
| Apartments | 4.8 | .... |
| **Washing machines:** | | |
| Houses | 23 | 32.8 |
| Apartments | 22.3 | .... |
| **Toasters:** | | |
| Houses | 16.5 | 18.5 |
| Apartments | 16.7 | 18.1 |
| **Percolators:** | | |
| Houses | 21 | 25.7 |
| Apartments | 22.7 | .... |

pliances was then segregated. The use of appliances, while heaviest on Tuesday owing to the ironing load, was remarkably well distributed through the other days of the week. The appliance consumption expressed as a percentage of the total consumption during this week was: "Above medium" houses, 44; "medium" houses, 37; "below medium" houses, 41.1. "Above medium" apartments, 26.9; "medium" apartments, 19.1; "below medium" apartments, not tested.

If it be assumed that 15 per cent of all houses served are "above medium," 45 per cent are "medium" and 40 per cent are "below medium," the weighted average of energy used for appliances by houses during the test week would be 41 per cent and for apartments 21 per cent of the total consumption.

The monthly variation of energy consumption is such that during the month of May the total consumption is about 75 per cent of the average for the year. In the case of the houses tested this would mean that if the appliance consumption is 41 per cent during May, it would average about 75 per cent of that amount, or 30 per cent, for the year. In the apartments tested it would be about 16 per cent for the year. In connection with the survey each customer was questioned as to the use of the various appliances in different months of the year. These customer estimates averaged about 20 per cent for houses and 14 per cent for apartments. This leaves a discrepancy between the 30 per cent for houses computed from tests and the 20 per cent obtained from estimates made after talking with the customer. In the case of apartments the figures of 16 per cent for the test and 14 per cent for the survey are in practical agreement. The difference in the case of houses may be attributable to a disposition to underestimate or to the possibility that seasonal variations in use of appliances are greater than was assumed in the calculations. It is probable that the correct figures for yearly appliance consumption for houses is between 20 per cent and 25 per cent.

The consumption of energy by the various appliances as computed from the joint estimates of customer and surveyor appears in Table III. In the same table is given the consumption of the same appliances as measured in the houses tested for one week multiplied by fifty to give a figure approximating annual consumption if the use of appliances is the same throughout fifty weeks of the year. Two weeks have been allowed for the customer's absence from home because of vacation or for other reasons.

An application of the data obtained to the Chicago residence rates and average consumption reveals an annual appliance use of about 68 kw.-hr. by the average customer, which adds about $2.75 per year to his bill. With a total of 500,000 residence customers, this adds $1,375,000 per year to a gross residence revenue of about $10,000,000, which is sufficient to make this class of business desirable to the company.

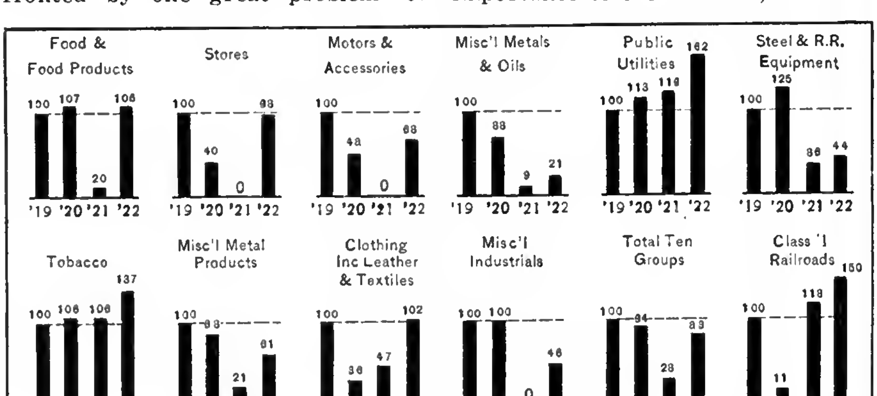
# Moody Classes Public Utility Securities as Most Desirable Investment

PUBLIC utility securities are now considered by high financial authorities as one of the most desirable forms of investment, and the reasons for this favorable opinion are stated concisely by John Moody, president of Moody's Investors' Service, who, in a recent special analysis of the public utility field, says:

"We have come to regard public utility securities taken as a whole as the most desirable and attractive class in the investment market today. More favorably and intelligently regulated than the steam railroads, fundamentally more stable in every respect than the average industrial enterprise, the public utilities of the country face an assured future confronted by one great problem—to finance expansion of their facilities rapidly enough to take care of the steadily increasing volume of business offered them."

"It is evident," Mr. Moody goes on, "that the power companies represent one of the most important and most stable of the basic industries; that their future, simply on the basis of past accomplishment, is definitely assured for a considerable time to come, and that well-placed mortgage bonds of the strongest of these companies may be freely classified among the highest grade of investment securities."

That the securities of these companies combine to a marked degree safety and stability, factors of prime importance to the investor, is shown



ANNUAL NET PROFITS OF 122 MANUFACTURING AND MERCHANDISING CONCERNS AND OF THE CLASS 1 RAILROADS (1919 PROFITS = 100 PER CENT)

in the accompanying chart from the March "Monthly Review" of the Federal Reserve Bank of New York. It represents graphically business profits for ten groups of industries in the years 1919-1922 inclusive. In this respect the public utilities stand head and shoulders above the other nine groups, a direct reflection of the fundamental soundness of the industry.

Either in good times or bad there is always a demand for electric light and power because these services are indispensable both to cities and rural communities, to individual householders and to large corporations. Thus the earnings of well-managed public utility companies are safeguarded by the very necessity of the service rendered.

## Promoting Rural Service in France

DEVELOPMENT of rural service in France is presenting much the same problems to the central-station companies there as it is in this country. Different methods of promoting the use of electricity by farmers have been tried, and a particularly interesting program that is in use by one company and might be used in similar form in this country has been described by William W. Brunswick, American Consul at La Rochelle.

To encourage the use of electrical energy in rural communities of that district where a certain prejudice exists against its use, the electric power company has been giving lectures upon the utility of electricity to the farmers and country people in general. The company has sent a circular letter to all possible users of electricity in the rural districts and has also published it in the local newspapers. The contents of this circular explain the many usages to which electricity can be applied on the farm, in the home and in farm buildings and are as follows:

1. *What One Can Do with a Kilowatt-Hour of Light*:

Economize 4 liters (1.05 gal.) of kerosene.

Illuminate during twenty-five hours the kitchen, the halls, the cellar, the blacksmith shop and the carriage house, a stable for twenty cows, a stable for sixteen horses, a sheepfold for 100 sheep, a hogpen for thirty hogs, a granary of 300 sq. m. (359 sq. yd.), a carriage house or harness room of 60 sq. m. (72 sq. yd.) a dairy of 40 sq. m. (48 sq. yd.), a shed of 100 sq. m. (119 sq. yd.)

Sew with a sewing machine during twenty hours.

Clean fifteen knives during one year.

Clip five horses or twenty-five sheep.

Heat water for shaving each morning during one month.

Light a cigar after each meal during five years.

Iron during four hours.

Warm your bed during four nights.

Heat your room during one hour.

Bring to a boiling point 9 liters (2.37 gal.) of water.

Fry fifteen chops in fifteen minutes.

Warm a coffee pot or dishes during five meals.

Warm your feet during ten hours.

Curl your hair each morning for twenty days.

Incubate 250 eggs.

2. *What One Can Do with a Kilowatt-Hour of Power*:

On the farm: Work an are (120 sq. yd.) to a depth of 30 cm. (11.81. in.); work two ares (240 sq. yd.) to a depth of 22 cm. (8.66 in.); work three ares (360 sq. yd.) to a depth of 15 cm. (5.90 in.); plough up the stubble of 4 ares (480 sq. yd.); illuminate the farm during two hours; irrigate a hectare (2½ acres) during fourteen hours with 3.50 m. (3.82 yd.) elevation.

In the barn: Thresh 140 sheaves of wheat of 3,500 kg. (7,716 lb.); illuminate the thrashing room during five hours.

In the dairy and cow barn: Milk with a machine twenty cows; separate the cream from 1,400 l. (370 gal.) of milk; heat 1,000 l. (264 gal.) of cream; churn 200 kg. (441 lb.) of butter.

In the wine shed: Crush 10,000 kg. (11 tons) of grapes; draw from barrel 300 hectoliters (7,925 gal.) of wine and pour into other barrels; crush 170 kg. (374 lb.) of the dead wood of vines; fill and cork 250 bottles.

In the granary: Lift seventy sacks of wheat to a height of 10 m. (33 ft.); sort 100 sacks of wheat; clean with winnowing machine 10 sacks of wheat; thrash 100 kg. (220 lb.) of oats.

In the bakehouse: Knead eight sacks of flour.

For your alimentation: Produce 4 kg. (8.8 lb.) of ice; raise 3,000 l. (793 gal.) of water to 20 m. (22 yd.); sterilize 10,000 l. (2,642 gal.) of water with ozone; crush 2,000 kg. (2.2 tons) of apples for cider.

In the work shop: Saw 90 m. (98 yd.) wood; sharpen 200 sections of blades for mowing machines.

In the feed room: Cut 400 l. (45.4 pecks) of oats for horses; crush 250 kg. (551 lb.) of furze; crush 600 kg. (1,323 lb.) of oil-cake; pound 100 kg. (220 lb.) of rye; pound 300 kg. (661 lb.) of corn; pound 200 kg. (441 lb.) of wheat; cut 5,000 kg. (5½ tons) of beets; cut 500 kg. (½ ton) of straw; mix 500 kg. (½ ton) of fertilizers; grind 50 kg. (10.23 lb.) of barley.

## The Economic Value of Street Lighting

SIX HUNDRED persons are killed each year in the United States because of inadequate street lighting, says a report of the American Society for Municipal Improvements. Property damage resulting from the same cause is put at $54,000,000 a year, whereas the entire country's bill for street lighting is but $50,000,000 a year.

Urging the need for higher standards of lighting as a preventive both of accidents and of crime, the society quotes municipal statistics showing that modern street lighting has reduced crime on certain streets as much as 41 per cent, as compared with other streets in the same cities.

## Chart Showing Stockholders Stimulates Sales

By Henry Bosch
Chief Draftsman Pacific Gas & Electric Company, San Francisco

TO STIMULATE its stock sales the Pacific Gas & Electric Company uses seventeen charts similar to the one shown in the accompanying illustration, which visualize graphically the actual number of

EVERY ONE OF 25,000 STOCKHOLDERS IS REPRESENTED BY A DOT

stockholders on the company's books. These charts measure 58 in. x 60 in. and are placed on an easel as shown. Each stockholder is represented by a colored dot $\frac{3}{16}$ in. in diameter. The annual stock sales are shown in relation to each other by using carefully selected color contrasts. Seventeen of these charts were made and placed on display in the various division offices of the company, at a cost of $35 each.

Although the advantage accruing from these charts is indirect, the attention given them by prospective stockholders has justified their existence. It is interesting to note that largely as a result of the favorable interest awakened by this display and other forms of publicity, the number of the company's stockholders increased by more than five thousand during the first five months after the appearance of these charts.

## Wiring Old Houses in St. Louis

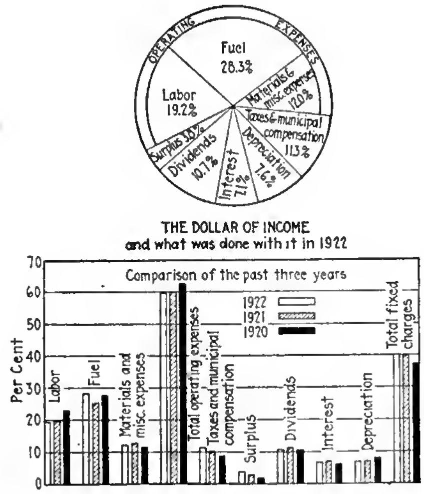
A HOUSE-WIRING campaign is being conducted by the Union Electric Light & Power Company of St. Louis which provides a financing plan whereby licensed electrical contractors may install wiring and fixtures in already-built homes and upon satisfactory completion of work may obtain payment in full from the company, which in turn will collect from the purchaser in monthly installments. The financing plan covers the new installation of wiring and fixtures or the installation of additional wiring and fixtures in already-wired homes, but does not cover Installation of fixtures only.

A contractor upon developing a "prospect" sends to the Union Electric Light & Power Company an inquiry for service and credit. The company makes investigation and notifies the contractor by letter as soon as the credit of the purchaser and availability of service have been established. The contractor receives payment from the company, upon completion of wiring and installation of fixtures, after the work has been inspected and approved by the municipal authorities, by presenting a signed contract for the work together with an initial payment of at least one-twelfth of the total and a statement from the purchaser that the work has been satisfactorily completed. The campaign was started on March 12 and will continue for an indefinite period.

## Commonwealth Edison Year Book Analyzes Growth

FOLLOWING the policy started in 1922 of acquainting stockholders with the details of their property and also furthering customer ownership, the Commonwealth Edison Company has just issued its 1923 Year Book. It contains a carefully prepared and condensed record of the company's growth presented in terms that any reader not generally familiar with financial statements can readily understand. The explanations of the income and expense account and the balance sheet follow in the same order as the customary annual report, but under each notation is a paragraph giving the details of and reason for that particular charge.

Included in the Year Book is President Insull's address to the stockholders at the annual meeting on Feb. 26, which was broadcasted by radio to stockholders and reported in the ELECTRICAL WORLD for March 3. The book shows the growth and



THE EDISON DOLLAR OF INCOME

The "wheel" represents the dollars received from customers during 1922. The "spokes" divide the dollar and show in percentages what was done with it. The blocks at the bottom of the chart compare the expenditures during 1922 with those of 1921 and 1920.

expansion of the company by charts and illustrations. Of particular interest is a diagram giving the proportionate expenditures of each dollar of income for operation, maintenance, interest, taxes, dividends and so forth. This diagram also gives a comparison of these expenditures for the past three years.

## What Other Companies Are Doing

**Albuquerque, N. M.**—The Albuquerque Gas & Electric Company proposes to apply for an extension of its franchise and has submitted a tentative schedule calling for a reduction in rates and increased service. It is probable that the city authorities will consider the installation of a better street-lighting system in connection with this matter.

**Chicago, Ill.**—The Utility Securities Company, which has grown out of the investment department of the Public Service Company of Northern Illinois and the Commonwealth Edison Company, is offering $250 in prizes for a better slogan than the one it is now using—"Investments that Endure." The requirements for the winning slogan are that it must not contain more than ten words and must be strong, direct, easy to grasp and easy to remember. To assist people in preparing slogans the company has issued a pamphlet listing a number of reasons why public utility securities are sound investments.

**Davenport, Iowa.**—A two-million-dollar group life insurance policy has been taken out by the United Light & Railway Company, covering its employees. Approximately two thousand employees of the company are protected by the policy, one thousand in the "Tri-Cities" and one thousand in other cities in Iowa, Illinois, Michigan, Indiana and Tennessee. The policy covers all employees in every department, irrespective of class of employment. The amount of insurance varies with the number of years each employee has been continuously in the company's service, up to ten years, after which the maximum amount, $1,500, is obtained.

**Salt Lake City, Utah.**—The good roads committee of the Salt Lake Chamber of Commerce, state, county and city officials witnessed a demonstration of a new system of highway lighting on the evening of March 23. The experimental system, consisting of fifteen highway units of 250 cp. each spread over a distance of about a mile at intervals of from 350 ft. to 400 ft., was installed at the instance of the good roads committee and the State Highway Commission. That part of the road selected for the demonstration was chosen because it presented the three most difficult problems in highway illumination, a curve, a hill and a railroad crossing. When the roadway was illuminated it was apparent that there was sufficient light at every point to make it safe to drive automobiles along the highway without headlights. The installation was made by engineers of the Utah Power & Light Company and the General Electric Company.

**Boston, Mass.**—Electric appliance sales in nine companies managed by Charles H. Tenney & Company totaled $19,698 for January, 1923, against $13,104 for January, 1922, a gain of about 50 per cent. The leading companies for the first month of this year were: Malden, Mass., $5,458; Fitchburg, Mass., $3,487; Salem, Mass., $3,027, and Montpelier, Vt., $2,995. As good an increase was marked in preliminary reports for February, 1923. For the week ended March 10 last twelve Tenney companies sold about $10,800 in appliances, of which some $8,100 were electric.

## Hydro-Electric Development and Steam Equipment

*Burning Pulverized Coal with Reduced Furnace Volumes.* — N. W. ARROWOOD.—The author argues that by thoroughly mixing coal and air in a proper burner moderate furnace volumes may be employed and excess air reduced; also, by injecting the fuel mixture into the furnace horizontally and at low velocity, temperatures will be highest at the center of the gas volume and lowest at the furnace walls. He describes the burner designed to meet these conditions.—*Power*, March 13, 1923.

*Gennevilliers Power Station.*—M. BLONDIN.—Five banks each consisting of three 60,000/3,000-volt single-phase transformers of 15,000 kva. are installed within this station. Each bank is directly connected to its 40,000-kw. turbo-generator set, with only current transformers between the two. The transformers are water-cooled. One bank of three 4,000-kva. single-phase transformers supplies the auxiliary power requirements. The oil switches used have a safe rupturing capacity of 600,000 kva. The Merz-Price selective protection system is used, protecting all feeders. To localize short-circuit currents within the internal power-supply system a number of air-core reactors are installed. These reactors are oil-cooled and are placed within tanks made of copper with a bottom and a cover of bronze. More than 125 km. of single-conductor, 60,000-volt underground cable has been laid out in concrete ducts, three cables in one duct representing one feeder. A very detailed description of this cable is given. The cable was successfully tested on the drums with 175,000 volts for one hour. Nine-petticoat porcelain bushings, cemented upon a bronze funnel, form the cable potheads, which were tested with 220,000 volts against ground.—*Revue Générale de l'Electricité*, March 3, 1923.

## Generation, Control, Switching and Protection

*Cable Protection System.*—W. PFANNKUCH.—This system, known under the name of the author, requires specially built cables with the main conductors in the center and a concentric layer of auxiliary conductors insulated from one another and from the main conductor. All of the conductors, however, transmit power according to their cross-section. At the start and the end of the cable a differentially connected combination current and potential transformer is connected to the cable, causing a slight potential difference between the main conductor and the outer conductors of the cable. As long as the cable is in perfect condition the magnetic fluxes in this special transformer resulting from the current and voltage windings will balance one another, and no current will be induced in the secondary winding. This protection system gives a warning signal for less than 1 per cent unbalance in the cable. The finding of a fault in the cable is much simplified by the aid of the insulated outer conductors and can be localized by calculation to within a few inches. The special construction of the cable increases its price about 5 per cent. The system is specially adapted to the protection of high-voltage cables and has been in successful operation for the last two years on transmission systems in Germany, Sweden, South America and Turkey, with voltages of 10,000 to 35,000.—*A.E.G. Mitteilungen*, February, 1923.

*Large-Capacity Oil Circuit Breakers.—I.*—G. BRÜHLMANN.—A large amount of valuable information on the construction and performance of oil circuit breakers can be found in this publication, dealing with the latest types of breakers up to the highest voltages. On breakers up to 500-amp. capacity no great attention need be paid to the contact surface as long as the contact pressure is high. Arcing tips are not required. Above 500 amp. well-designed brushes combined with high pressure and arcing tips must be used. Excellent insulation, avoiding dangerous creepage, is essential. In the open position only oil should be used between live and dead parts of the switch. All breakers must withstand repeated closing upon a short circuit without necessitating an inspection of the contacts. Abnormal generation of smoke may cause an arcing against the tank or between phases, against which insulating casings and partitions of heavy material are a reliable remedy. The gases developed in the oil at a violent rupture are inflammable and give, mixed with air, an explosive mixture. To avoid ignition of these gases the oil level should be high enough above the contacts to cool these gases below the flame point before they reach the oil surface. The sudden generation of these gases causes pressures of up to 8 atmospheres within the oil tank, and these pressures are usually of an oscillatory character having about 500 cycles per second. Steel boxes with very carefully made welded joints, with seams slightly beyond the edge of the tank, gave the most reliable switch tanks, rupturing at about four times the expected pressure. A contact arrangement with multiple breaks shortens the duration of the arc and lessens the danger of ignition of the gases. Congealed oil is very dangerous, because it slows down the speed of the opening and prevents the quick quenching of the arc. Using oil under pressure, as suggested repeatedly in the literature of the subject, was found in actual tests to be a decided disadvantage. With oil under 7 atmospheres pressure the arc lasted 70 per cent longer as compared with its performance under barometric pressure. At the same time, the volume of generated gases amounted to about twenty times the volume without the pressure. Excellent protection of the switch itself may be obtained with a resistor connected externally between one of the contacts and the two middle contacts (quadruple break), for which purpose a third insulated lead is usually provided on the cover of a single-phase breaker. — *Brown-Boveri Mitteilungen*. March, 1923.

## Transmission, Substations and Distribution

*Applications of Heaviside Expansion Theorem.*—LOUIS COHEN.—The author has worked out a few examples relating to somewhat different branches of electrical engineering, in order to show the wide range of application of the expansion theorem in the solution of electrical problems.—*Journal of the Franklin Institute*, March, 1923.

*Three-Phase, Four-Wire Distribution Systems.*—H. W. SMITH.—The characteristics of the three-phase, four-wire primary circuits as an ideal system of distribution are fully discussed by the author. He points out that even in very small communities this four-wire system has many advantages. Single-phase branch-feeders can be tapped from a main feeder at any point, and the improvement in regulation obtained by tying together the neutrals of two long single-phase feeders fed from a four-wire main is quite large. Small blocks of polyphase power can be supplied much more cheaply than by any other system. The necessary changes in equipment motors, transformers, etc., upon the adoption of the four-wire system are related.—*Electric Journal*, April, 1923.

## Units, Measurements and Instruments

*Derivation of Hydraulic Equation for Gage Relations and Discharges.*— D. K. C. STRATHEARN.—Methods of deriving gage relation and discharge equations employed during the recent St. Lawrence River power investigation are described.—*Canadian Engineer*, March 20, 1923.

*Current Capacity of Wires and Cables.*—G. E. LUKE.—In the December, 1919, issue of the *Electric Journal* a table giving the current capacity of conductors in still air outdoors for 40 deg. C. rise was published. Extensive tests conducted by the author and made with carefully calibrated instruments under most favorable conditions indicate that the temperatures produced by a given current are considerably higher

than indicated by the formula which was the basis of the above-mentioned table. These tests have been furthermore corroborated by entirely independent tests, which, though not extensive, check closely. The results of the author's tests are given. — *Electric Journal*, April, 1922.

### Illumination

*Ornamental Street-Lamp Installation.* —In spite of the fact that proper street lighting has been found to reduce the number of accidents, the advance in the use of new lighting units has not been so rapid as the advance in other civic improvements. This article gives data on accidents caused by inadequate illumination and on cost of street lighting and information on other important features.—*Journal of Electricity and Western Industry*, March 1, 1923.

*Car-Lighting Maintenance Methods.* —Regularity in greasing and inspection of car-lighting equipment is unquestionably one of the first requisites for its successful operation. Very good results have been accomplished on the Erie Railroad by the inauguration of a system of record keeping by means of which it becomes practically impossible for any car to be neglected without that fact being known at headquarters. Typical forms are included which include greasing and overhauling reports, inspection of axle-light equipment, battery-flushing chart, ball-bearing inspection, etc.—*Railway Electrical Engineer*, March, 1923.

### Motors and Control

*Electrification of a Large Carpet Mill.*—H. KETTON.—A detailed description is given of the complete electrification of a very large and old-established factory in which a complex series of processes contribute to the manufacture of the finished products. About 4,000 hp. of motors, together with the necessary power plant, were installed with practically no stoppage of work. A very detailed description is given of the power plant and the arrangement of the various machines.—*English Electric Journal*, Vol. 2, No. 3.

*Variable-Speed Alternating-Current Motors Without Commutators.* — F. CREEDY.—After a short general discussion, a new method of pole changing, involving the use of a number of phases greater than that in the line, is explained, together with means for simplifying the connections by the use of mutually reversed coils and by a star-mesh connection. The phase transformer needed to produce the increased number of phases is next decribed, and it is shown that the current in the windings intermediate between the three-phase tapping points is reduced to a very low value as in the rotary converter, making the apparatus small and inexpensive. The switchgear employed is discussed, and it is pointed out that the methods described render the squirrel-cage motor adaptable to almost all purposes, since they enable it to give good starting torque with low current. Machines with slip-ring characteristics are also described and test results discussed. A description is given of the cascade motor, and its unique characteristic of giving gradual adjustment between speeds is explained. Two-speed, three-speed and four-speed motors having this characteristic are referred to. Some tests of large rolling-mill and other motors are described, and finally an account is given of the application of the cascade motor as a short-circuit motor machine with slip-ring characteristics and as a unity-power-factor synchronous machine of greater simplicity and less cost than any other type.—*Journal of Institution of (British) Electrical Engineers*, March, 1923.

*Flywheels on Rolling-Mill Drives.*—F. R. BURT.—Various mill power loads and rolling characteristics which determine the advisability of flywheels for such service are discussed. In determining the size of the motor for driving a mill, both the root-mean-square or equivalent heating load and the peak load must be considered. The relative importance of heating and peak load depend roughly on what percentage of the total passes contain metal simultaneously. — *Blast Furnace and Steel Plant*, March, 1923.

### Heat Applications and Material Handling

*Scrapping Steel Cars by Means of the Carbon Arc.*—E. H. DRALLE.—The electric cutting process has proved to be an economical method of reducing scrap to sizes that can be handled and cut by shears. The work done thus far on dismantling cars by the carbon-arc process has shown that this method is decidedly superior to other methods of scrapping, and it is entirely possible that a more widespread use of this process will result in an improved means for wrecking cars which will still further decrease the already low cost of dismantling by the arc process. —*Railway Electrical Engineer*, March, 1923.

### Telegraphy, Telephony, Radio and Signals

*Wireless Antennas.*—From a consideration of the usual radiating structure it is evident that in many cases great improvement is possible, and methods by which improvement may be achieved are described. A method of calculating the various antenna constants is given. —*Wireless World and Radio Review*, Feb. 17 and March 17, 1923.

*Wind-Pressure Assumptions as Affecting the Design of Radio Towers and Masts.*—In all theory, design and specifications some assumptions are necessary, and as experience is gained the value and accuracy of these assumptions are made apparent. The ultimate weight and cost of a structure are influenced in no small degree by the initial considerations, and in the particular field under review the question of maximum wind pressures and the law connecting such pressures with height above ground level are of primary importance. The paper reviews briefly the results of past experiments and endeavors to point out what are safe and economic values of wind pressures for design purposes. The need for the standardization of wind-pressure assumptions is also brought out.—*Journal of the Institution of (British) Electrical Engineers*, March, 1923.

*The Hot-Cathode Rectifier as Applied to Radio Transmitters.*—D. G. LITTLE.—This rectifier has found a new application as a source of high-voltage direct current in connection with radio telephone and telegraph transmitting apparatus. The difficulties of a direct-current generator for voltages of 2,000 v. and above are overcome with the rectifier. Circuit diagrams and characteristic curves of this rectifier are given. The hot-cathode rectifier, using tubes of the high-vacuum electron type, offers a very convenient means of obtaining direct-current power from alternating-current supply when the current required is 5 amp. or less with voltages of 2,000 to 20,000 or even higher.—*Electric Journal*, April, 1923.

*Flat-Type Relays for Telephone Circuits.*—D. D. MILLER.—A relay for opening and closing telephone circuits is described that is flexible, reliable and economical. This relay is made up in three thousand varieties of windings and switching arrangements, but is essentially a punch-press product. — *Electrical Communication* (published quarterly by the International Western Electric Company), February, 1923.

### Miscellaneous

*Future Industrial Use of Electron Tubes.*—M. LEBLANC.—Having solved practically all mechanical difficulties in the design of electron tubes up to about 1,000 kw. output, the author foresees in a somewhat visionary article, the future uses of these tubes for industrial purposes. With the possibility of building what the writer calls an electromagnetic valve, it is theoretically easy to transform alternating current into direct current of high voltage, to transmit this current and to transform it at the end of the line back to alternating current with a satisfactory over-all efficiency. It would further be possible to use a high-frequency alternating current to transmit energy to locomotives or electrically driven automobiles without a metallic connection between the source and the vehicle. An overhead or underground condenser-trolley fed with 20,000-cycle alternating current could be devised within the field of which the vehicle, which would contain a secondary winding, would run. In this winding a high-frequency alternating current would be induced which could be transformed with the aid of electromagnetic valves into three-phase current of low frequency to energize the motor and control equipment of the vehicle.—*Bulletin de la Société Française des Electriciens*, January, 1923.

## New Telegraphic Alphabet

**System Invented by General Squier Doubles Speed of Radio, Wire and Cable Systems**

INVENTION of a new telegraphic transmitting alphabet applicable alike to radio, land lines and submarine cables was announced by Major-Gen. George O. Squier, Chief Signal Officer, U.S.A., at the annual meeting at Washington last Tuesday of the National Academy of Sciences. This alphabet, General Squier said, was more than two and a half times as fast as the international Morse alphabet now employed.

The principle upon which the new method is based is that the dots and dashes occupy equal lengths of time. No consecutive signals are of the same size, and the limit of legibility for each letter of the alphabet is practically uniform. The dots, dashes and spaces are differentiated by different intensities of the sinusoidal wave employed, in exactly the same manner that music and speech are formed. The principles of the new alphabet, General Squier said, serve to bring telegraphy into line with telephony and to base the two arts on the same fundamental principle of modulation.

General Squier claimed in his paper that this method of transmitting messages offers a plausible solution of the problem of interference and of "static" elimination and also of multiplexing a single radio-frequency channel.

## Burgess Heads Standards

**Appointed by President to the Post of Director of Bureau to Succeed Dr. Stratton**

AT THE suggestion of Secretary of Commerce Hoover, the President has appointed George K. Burgess to be director of the Bureau of Standards. Since 1913 he has been chief of the bureau's division of metallurgy. His service with the bureau dates from 1903, when he was appointed as an associate physicist. In 1905 he was promoted to be a physicist.

The appointment of Mr. Burgess follows several months of futile search on the part of Secretary Hoover for an outstanding physicist who had not been connected with the government service and who had sufficient means to allow him to make the sacrifice of income which would be entailed in the acceptance of a bureau directorship. Mr. Hoover's investigations revealed that physicists in the front rank of their profession are being paid salaries ranging from $18,000 to $20,000. He combed the country for a man possessing the requisite qualifications for this important government post, but found no one who was acceptable to him who could be induced to take the place at the salary available.

While it was Mr. Hoover's desire to bring into the bureau a man from the outside who could be expected to have ideas and plans prompted by his outside contacts, he recognized that the next best thing would be to promote some member of the bureau's staff, who would have the advantage of an intimate knowledge of its work and problems. His choice happened to fall on the ranking member of the bureau's staff, and Mr. Burgess' colleagues are unanimous in agreeing that he is best qualified to undertake the directorship.

©Harris & Ewing

George K. Burgess

Mr. Burgess was born at Newton, Mass., in 1874. He received his B. S. from the Massachusetts Institute of Technology in 1896, and he held a fellowship at that institution from 1898 to 1900. His Sc.D. was obtained in Paris in 1901. He served short terms as instructor at the University of Michigan and at the University of California. He is the author of a number of scientific articles and treatises.

Mr. Burgess has been active in the work of the National Research Council. During the war, in addition to his regular duties, he was an adviser to the requirements division of the War Industries Board and to the Ordnance Department of the army. In 1917 and 1918 he was chairman of the light alloys committee of the National Advisory Committee for Aeronautics. During the same period he was a member of the National Aircraft Standards Board.

## Smith Bills Slaughtered

**Assembly Defeats All Utility Measures by 69 to 59—Water-Power Bill Awaits Same Fate**

BY A VOTE of sixty-nine to fifty-nine on almost straight partisan lines, the Republican Assembly at Albany defeated on Wednesday the six public utility bills advocated by Governor Smith of New York. These bills had all passed the Democratic Senate. It is very unlikely that they can be brought up again this session. The New York City transit bill had been killed in the Assembly the day before. The Governor's water-power bill has not yet been brought to a vote in the Assembly, where the same fate in all probability awaits it. The six bills slaughtered Wednesday were:

The bill to create a department of public utilities for New York City, with power to own, lease, operate and control gas plants, electric plants, heating plants and telephone lines.

The bill to abolish the present Public Service Commission of five members and create in its place a commission of three, to be appointed by the Governor.

Senator Walker's so-called 5-cent fare bill, which would restore to up-state cities full power over franchise agreements with traction companies.

The bill to permit all cities to own, operate, lease and control public utilities, designed chiefly for up-state cities, so that they would have the same broad powers as were designed for New York City.

The bill to create public utility commissions in up-State cities to have control over utilities which the city might elect to own or operate, the commissions to have the same powers as the present Public Service Commission exercises.

A bill to change the wording of the Public Service Commissions law to make it conform with the proposed legislation.

## Newfoundland to Vote on Big Hydro-Electric Program

Newfoundland has been called upon, by the dissolution of its Parliament, to determine whether it wishes its vast natural resources developed by the harnessing of the unlimited power of the Humber River and the utilization of its lumber reserves for the manufacture of paper. Sir Richard Squires, leader of the Liberal party in Newfoundland, is appealing to the country for a mandate to put through a huge water-power development program with

resultant pulp and paper mills having a daily capacity of 400 tons, together with various other industrial programs. The water-power development program will be undertaken under the joint guarantee of the British government and the Newfoundland government provided that the people of Newfoundland indorse the proposal at the polls. Sir Michael Cashin, the executive head of the opposing party, is aggressively opposed to the program and has issued a circular to the electorate describing the undertaking as visionary.

The entire north and west sections of Newfoundland are strongly supporting the industrial development policy of Premier Squires, but Sir Michael Cashin is said to have a considerable following in the southeast section. The opposition is attributed to a feeling among the big fishing interests that inland industrial development will take their labor away, consequently compelling them to pay higher wages to fishermen. It is predicted that Premier Squires will be indorsed by a very large majority.

# Triumph of Superpower Seen

## Spring Convention of A. I. E. E. Discusses Technique and Policy of Electric Power Supply, Indorsing Use of Grounded Neutral and Ground Relays

ALMOST a thousand engineers from all parts of the United States and some from foreign lands listened at Pittsburgh this week to the group of splendid technical papers, filled with operating data, field experience and technical analysis of important subjects in the light and power industry, that were presented at the spring convention of the American Institute of Electrical Engineers. The papers and the discussions which followed were noteworthy for the crystallization of opinion as to the best engineering practice to be followed in lines which have been largely controversial heretofore. The use of the grounded neutral and of ground relays was accepted by power engineers and telephone engineers alike, the only difference of opinion being in regard to the use of high or low resistance, the number of multiple grounding points and similar details. It was generally accepted that no agreement on a single method applicable to all systems was likely to be reached, the individual characteristics of systems determining the exact method on each system.

### Petersen Coil Discussed

Experience with the Petersen coil was presented, indicating its usefulness at least on low-voltage, singly-fed, single-circuit lines. More extended use of grounded relays, greater perfection in the relays themselves and the development of two new types were the outstanding points in the discussion on relays. The balanced-differential current relay had its first installation on the Duquesne Light Company's ring. The second new type was a distance time relay involving the application of a voltage coil and a current coil and the balanced-differential principle.

The electric furnace session brought out the admittedly good performance in the steel industry and the trend toward its wider application to the production of alloys. The magnetic-field effect on atomic structures in the operation of the electric furnace and its application to refining processes were suggested for investigation. More refined tests on steam locomotives indicated further advance in locomotive practice, but discussion showed that electrification still offers advantages over steam operation.

### Superpower the Banquet Theme

By their applause of the speakers at the banquet on Wednesday evening the seven hundred men in attendance put themselves on record as in favor of a vigorous policy of superpower development and indorsed the necessity of interstate and international networks which must be allowed to develop unfettered by the restrictions of state lines, of needlessly obstructive laws and of politics. There was an agreement that politicians must be educated by educating the public, rural as well as urban, to the benefit which will inure to it as a result of an intelligent utilization of the country's natural power resources.

Three addresses were made on this subject in addition to the remarks of President F. B. Jewett, who served as toastmaster. President Jewett dwelt on the point that all the many necessary, useful and enjoyable things that the human race has learned to do or make require power somewhere, either in operation or in construction. Therefore, as the use of these things grows and as consequently the use of power grows, there must ultimately come a time when man will have to reduce his wants because of lack of power-producing facilities unless he meanwhile develops a plan for more efficient power production and utilization. In this regard superpower development with a maximum use of water power plays a necessary part.

Paul T. Brady of the Westinghouse Electric & Manufacturing Company recalled the advance made during his lifetime in the development and use of electric power and predicted unlimited future development, but showed that interconnection was an economic necessity for adequate utilization of resources to supply the necessary power. He said in part:

"To take the next step in social progress, not only must we utilize our water-power resources to the fullest extent, but we must also use huge steam plants which will supplement the water power. The ideal location for these steam plants is beside the rivers of the coal regions, where fuel can be delivered to the boilers with a minimum of transportation and where ample supplies of condensing water can be obtained. There is a tendency on the part of certain power engineers connected with plants thus favorably located to take a short-sighted view of the power situation. 'Why should our plants co-operate with water-power plants?' they ask. 'Here we have abundant supplies of cheap fuel for generations to come. We can gain nothing by becoming part of a larger system and are therefore not interested in the project.'

"These people forget that outside the narrow limits of their own systems there are millions of people who are either paying high prices for electricity or are unable to get it at any price. They forget that their properties form an essential element in any plan to supply the country as a whole with power at the lowest cost. They forget that, if their plants become a part of such a system, they will have the widest possible market for their excess power and their surplus coal. They forget that, after all, their systems are not absolutely self-sufficient and that, unless connected with other sources of power, they may fail to give service in event of serious accidents. Finally, they forget that it is precisely this attitude of self-interest that forms one of the strongest arguments for the governmental ownership of the unified power systems. They must see the larger picture. Up north in Canada there is 18,000,000 hp. of the finest water power in the world; down here in Pennsylvania, West Virginia and Ohio there are billions of tons of coal. Employed separately, each will indeed benefit many people, but used together to the best advantage they will bring ever-increasing prosperity to all of the people in Northeastern North America.

### Better Work Must Follow Good

"I must not be understood to be criticising our central stations. Their splendid work has alone made possible life as we know it today and has opened the way to the even fuller life that we can confidently expect the next generation to enjoy. Furthermore, no one can be censured for acting in the best interests of his own people, but good work is no excuse for not doing better work. Nothing better can be given to the people of the United States and Canada than a single international power system that will permit the utilization of our water power and coal to the best advantage and will provide every one with an abundant supply of electricity."

R. F. Schuchardt of Chicago, in discussing engineering phases of superpower, also traced the growth of power and its effect on civilization. "Cheap power has caused a rapid growth in industrial centers, and every com-

munity that has had this cheap power has prospered," he said. Virtually every European country has appointed a commission to study the means of obtaining most economically power to offset the great loss in man power, and they turned for guidance to what they term the superpower systems of America. But America is not resting on her oars, Mr. Schuchardt continued. She is going ahead to develop more power economically to relieve mankind and maintain her industrial supremacy and high standards and at the same time retain for American labor and American investment their fair share of the world's trade. Interconnection and still more interconnection is the answer, and this is at once in the interest of the industry and of the nation.

As to the engineering, it is its work to save fuel and dollars, dollars meaning labor and material. Fuel economies are understood. Dollars are saved by realizing savings due to diversity factor, a natural result of interconnection. Mr. Schuchardt issued a challenge to and yet expressed confidence in the engineer when he spoke as follows:

### WHO SHALL SET THE STANDARDS?

"The electricity supply industry in its onward march is bringing about many extensive interconnections. Is this development following a definite, logical engineering plan? No such plan has as yet been developed except that for the North Atlantic Coast area. What assurance have we that when the grouping of groups which is on the horizon arrives the systems will be found readily adaptable to economical interconnection? Is the frequency common and how about the voltages? Who should set up the standards and see that investments made for present extensions will have their proper value in the coming years? Who will see to it that the industry lives up to its obligation, to its trust? Naturally, the industry itself, for it is keenly alive to its obligation. Already there are committees of the industry's organization, the National Electric Light Association, studying the problem in various parts of the country, and more will undoubtedly be formed. The society of the profession most interested—that is, the American Institute of Electrical Engineers—will be an important factor in solving the problem, of course. Co-operation between all these will assure uniformity at least in the fundamentals of such studies."

M. H. Aylesworth, discussing superpower as a national policy, said in part:

"As professional engineers have good reason to know, the installation of superpower stations and systems is not hindered by questions of engineering but by weightier matters of finance, law, economics, politics and policy. These handicaps still beset us, and when they are once disposed of superpower stations will spring up with remarkable rapidity. The whole trend of economics in tho electrical industry is toward larger stations and systems, and notable examples of these are to be found here in the Pittsburgh district and in numerous other sections of the country. Eventually the United States will be studded with large superpower stations, for the ultimate destiny of the country is to be covered with a network of interconnected transmission lines fed from such stations and reaching every city, town and village.

### BULK SUPPLY NOT NEW

"The idea of bulk supply is not new; it is as old as the electric lighting industry itself. From the very beginning it was recognized that the economics of the situation demand that the supply of electricity for the home, for the store, for the factory and for transportation should come from one central source. Manifestly, if we are to maintain the high standard of living which is characteristic of America, the per capita earnings of the country must also be high. With the competitive markets of the world, it would be impossible to bring this about without the aid of machinery, and therefore in this country use is made of every trade facility, invention and appliance. The United States, through its great use of machinery and electricity, is able to maintain a higher standard of living than any other country because its labor produces more and earns more. During the twenty years prior to the war the annual national per capita earnings in the United States increased 116 per cent, those of Germany 52 per cent, France 27 per cent, and Great Britain 21 per cent.

"These percentages reveal much. They show what an enormous influence cheap power, which means electricity, has on the productive capacity of a nation and people, and it is chiefly because they are such great users of electricity that Americans excel in so many directions. But if we are to continue to enjoy an abundant and cheap supply of power, we must concentrate more and more in its production; we must erect fewer but larger stations; we must develop our water powers, conserve our fuel resources, and through interconnected networks of transmission lines make power available in every market. Full use of power means taking the city to the farm, giving city electrical facilities to the farmer, and this will be the salvation of this country.

### SUPERPOWER AND CIVILIZATION

"Superpower is a measure of advancing civilization. It is machinery raised to the $n$th degree, superseding municipal and state boundaries and becoming national and continental in its character. It can find no abiding place in countries where life is primitive and labor cheap.

"The advance of machinery and of unified operation has had in past generations to combat two fears—the fear of the hand workman that his displacement means his destruction and the fear of the people at large that monopolies for their exploitation and oppression will spring up. The march of events in America has shown that—aside from such temporary individual hardships, regrettable, but inevitable, as every great change must bring—both fears are illusory. Nowhere else is machinery so firmly installed and nowhere else is the workman half so prosperous. Nowhere else are public service companies so large and so tied together and nowhere else are their rates and their service more firmly under the control of governmental agencies for the protection of their customers and the public at large. Superpower is a further extension of the principles of machinery and co-operation. Government regulation and customer ownership will travel with it. Cheaper energy, better service, progress, prosperity, profit and plenty will follow in its train."

Several inspection trips, including one by special train to the Westinghouse works, were scheduled for Thursday afternoon and Friday.

## Massachusetts Superpower

**Bill Signed by Governor Cox Foreshadows Union Plants at Fall River and Other Points**

AN IMPORTANT step toward economic power development occurred last week in Massachusetts when Gov. Channing Cox signed a bill permitting electric light and power companies to unite in financing and building generating stations and the necessary interconnecting transmission lines and equipment. Hitherto plant developments have been by individual companies, but the new law enables the advantages of interconnection and the supply of larger areas from tidewater stations to be realized more effectively through co-operative action by utilities interested in comprehensive developments. The Department of Public Utilities will maintain its usual regulatory interest in what is done.

The bill was brought before the present session for the immediate purpose of financing and building a plant of 200,000 kw. ultimate capacity on Mount Hope Bay, Fall River, in the interest of the Fall River Electric Light Company, the Edison Electric Illuminating Company of Brockton, Mass., and the Blackstone Valley Gas & Electric Company of Pawtucket and Woonsocket, R. I. The general program of this development by the proposed Montaup Electric Company has been reported in a former issue of the ELECTRICAL WORLD (issue of March 17, page 648). Energy will be transmitted from Fall River to the Brockton and the Pawtucket-Woonsocket districts. The initial outlay will total about $5,500,000 and will include the generating station, a 30,000-kw. generating unit, boilers, auxiliaries and a part of the transmission lines. The first unit is to be placed in operation in 1924 and a second unit soon afterward. The design and construction of plant and lines will be handled by Stone & Webster, Inc., Boston, under whose management are the Blackstone Valley and Brockton companies.

# Schuyler S. Wheeler Dies Suddenly

## Noted Electrical Inventor, Manufacturer and Engineer Was in Full Tide of Vigor—Edison Pioneer, Builder of Ampere, N. J., and a Leading Exponent of Professional Ethics

SCHUYLER SKAATS WHEELER, electrical inventor, engineer and manufacturer, who was president of the Crocker-Wheeler Company of New York and Ampere, N. J., died suddenly of angina pectoris on Friday, April 20, at his home in New York City. Funeral services, attended by many men prominent in the electrical industry and in scientific and other circles, were held in St. Bartholomew's Church on Monday. Among the organizations represented were the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the American Society of Civil Engineers, the International Electrotechnical Commission, the New York Electrical Society, the Chambers of Commerce of the United States and New York State, the Electrical Manufacturers' Club and the Electric Power Club. The pallbearers included Dr. Michael I. Pupin, Charles G. Curtis, John W. Lieb, A. L. Doremus and J. J. Carty.

Many messages of sympathy and tributes to Mr. Wheeler's character, ability and accomplishments were received at his home from men of prominence in the engineering world—among them Dr. M. I. Pupin, professor of electromechanics at Columbia University; Charles G. Curtis, with whom and the late F. B. Crocker Mr. Wheeler first entered the manufacturing business; Frank B. Jewett, president of the American Institute of Electrical Engineers; Alfred D. Flinn, secretary of the United Engineering Society; John J. Carty, vice-president American Telephone & Telegraph Co., and James H. McGraw, president McGraw-Hill Company.

Born in New York City not quite sixty-three years ago, the son of James E. and Annie Skaats Wheeler, Schuyler Skaats Wheeler came of age at the very time when electric light was emerging from the laboratories of the inventors to illuminate the streets and buildings of cities and villages. He left Columbia College in 1881 and obtained the post of assistant electrician in the American branch of the Jablochkoff Electric Light Company, subsequently transferring his services to the United States Electric Light Company, at that time coming into the field with the direct-current arc lamp, and then, with an unfailing sense of the lines along which electrical progress would be made, seeking and obtaining a place on the staff of Thomas A. Edison. Young Wheeler was one of the historic group present at the opening of the Pearl Street central station in New York City forty-one years ago. He superintended the installation of a number of the distribution systems that followed this pioneer—notably the underground systems at Fall River, Mass., and Newburgh, N. Y., and was in charge of operation in the latter city.

The field of invention and manufacturing soon, however, came to have a greater appeal to the young electrical engineer than that of installing and operating plants, and in 1886, after acting as electrician for the Herzog Teleseme Company, to which he contributed important inventions, he became connected with the C. & C. Electric Motor Company, just organized by two friends of his, Charles G. Curtis, of Curtis turbine fame, and the late Francis B. Croker, whose name and Wheeler's became permanently associated and who died two years ago. The C. & C. company manufactured small electric motors—a novelty at that time—and, under Dr. Wheeler's guidance as designer, electrician and factory manager, the company grew rapidly. In 1887 and 1888, however, Crocker and Wheeler severed their connection with it and founded the Crocker-Wheeler Company, of which Dr. Wheeler was president from 1889—when Mr. Crocker was appointed to the newly established chair of electrical engineering at Columbia University—to the time of his death. This company at once assumed and has always maintained a foremost position in the manufacture of motors.

Schuyler S. Wheeler

From 1888 until 1895 Dr. Wheeler, in addition to his private business, acted as electrical expert of the Board of Electrical Control for New York, during which time the task fell to him of seeing that all overhead lines were placed under ground. He carried out this duty faithfully and energetically and did not hesitate to remove poles by force when other means failed. In the year last named he resigned his municipal duties to devote his whole time to his manufacturing enterprise.

It was in 1895 that the works of the company, which a few years after its organization had been moved to the new town of Ampere, near East Orange, N. J.—a town that owes its existence and its name to the Crocker-Wheeler Company—were completely destroyed by fire. Almost before the ashes had cooled a larger and ultra-modern plant began to rise on the same site, while the business of manufacture went on in tents and sheds with electrically driven tools. The company was able to fill most of its orders, its business continued to increase by leaps and bounds, and the disaster was changed into an ultimate blessing.

The Latimer Clark library, the largest collection in existence of electrical books, was purchased by Dr. Wheeler in 1900 and presented to the American Institute of Electrical Engineers. This splendid collection contains every publication in the English language on the subject of electricity printed prior to 1886, including the rare sixteenth and seventeenth century works. It forms a literary monument alike to Dr. Wheeler's love of learning and his public spirit. He served as president of the Institute in 1905-06 and was at the time of his death chairman of the committee on code of principles of professional conduct, a subject that appealed to him so strongly that he had made it the theme of his inaugural presidential address, in which he expounded the duty of the engineer to his client, to the public and to his professional society.

Dr. Wheeler is said to have himself designed more than a thousand electric drives, including those for the complete equipment of the Government Printing Office and the Bureau of Engraving and Printing at Washington and other government plants. His activities and sympathies were not, however, limited to his great manufacturing enterprise. Besides the A. I. E. E., he was a member of the American Society of Civil Engineers and the American Society of Mechanical Engineers and was one of

the founders of the United Engineering Society. As recently as last November he served as one of the American representatives at the meeting of the International Electrotechnical Commission held at Geneva, Switzerland, and while in Europe he visited a number of countries, attending meetings of those interested in electrical manufacturing problems and investigating post-war conditions as they affected the electrical industry.

One side of his nature was shown by his institution at Ampere of a workroom devoted to teaching blind men and women to wind armature coils with tape. During the war this enterprise was carried on with special reference to soldiers who had lost their sight, and some of these were trained to be themselves teachers of others.

He contributed articles on technical subjects to various magazines and engineering journals, and his book on the "Practical Management of Dynamos and Motors," written in his earlier years conjointly with Professor Crocker, went through a number of editions and attained a large circulation.

### As Organizer and Executive

Perhaps a better estimate of Dr. Wheeler's abilities and the personal characteristics on which was built his great success as an engineer-manufacturer could not be given than that made many years ago, but as relevant today as ever, by Gano S. Dunn, then chief engineer of the Crocker-Wheeler Company, now president of the J. G. White Engineering Corporation. Mr. Dunn said:

"While Dr. Wheeler possesses the true engineering mind, that broad judgment which seems to rise above calculations and intuitively determine the salient principles of an engineering problem, and while it is to this characteristic, producing valuable inventions and designs, that his early successes were due, it is not in this direction that he has done his latest and best work. It is as an organizer and an executive, as an inventor of new methods of factory operation, to win success out of latter-day competition, that he has been pre-eminently successful and has blazed a way into a comparatively new country of manufacturing economics. Industrial organization in this country is carrying the lamp of progress far ahead into the darkness of old-fashioned and inadequate methods, and to such progress Dr. Wheeler is one of the men who have made great contributions."

Describing in some slight detail how meticulously every item of material and every finished part was followed through the factory by ledger entries, and how the writing of specifications, the issuing of orders and requisitions and the reporting of receipts and deliveries were checked at every step by a system that worked almost automatically, Mr. Dunn said:

"The result of such provisions for dealing with the minute as well as with the greater elements of manufacture has proved to be a greatly increased output, a diminished cost of production, a minimum of capital locked up in inactive stock, shutdowns for inventories no longer a necessity, and a promptness and certainty of delivery that attract business. The mob, organized into files, ranks, corporals, sergeants, captains, becomes an army, mobile and efficient. Many others have contributed to the higher industrial organization here referred to, but Dr. Wheeler has led in carrying it to some of its most successful developments."

He was a member of the Chamber of Commerce of New York and of the American Association for the Advancement of Science, as well as of a number of social and country clubs. He was also a director of the City Trust Company of Newark and of the Helicopter Company, Inc. Of the latter he was secretary.

In 1904 Dr. Wheeler received the John Scott medal of the Franklin Institute for the invention of the electric buzz fan. The degree of doctor of science was conferred on him by Hobart University, Geneva, N. Y., in 1894. Besides his New York residence, he maintained a home at Bernardsville, N. J.

## Cut in Commercial Lighting Rates of Detroit Edison

A reduction in the commercial lighting rates of the Detroit Edison Company has been directed by the Michigan Public Utilities Commission, this cut taking place in the second rate block and bringing a rate of 4 cents a kilowatt-hour in that block instead of 5 cents as formerly. This restores the pre-war rate.

Alex Dow, president of the company, in commenting on the order said: "The proposed reduction of commercial rates is in accordance with the arrangement arrived at a year ago with the Public Utilities Commission. At that time the question arose whether available earnings should be applied to reduce the rate for residential service, or the rate for commercial service, or should be split between the two, and it was the opinion of the commission, and ordered by it, that the reduction should be made in the rate for residential service as the place where it would do most good to the ultimate consumer, with the understanding that as soon as continuing improvement of business warranted further reduction would be given to the commercial consumer. This present reduction carries out that understanding. It is warranted by the present and expected earnings of this fiscal year.

"General business conditions in Detroit are very good," Mr. Dow went on, "and the demand for new connections and industrial power is likely to run over available capacity during the fall of the year. The output from the company's plants for the first three months of this year was 339,000,000 kw.-hr. as compared with 242,000,000 kw.-hr. for the similar period last year."

## Southern Power to Go Slow

### Soaring Construction Prices May Cause Postponement of Contemplated New Development

Reports from North Carolina indicate that increasing building costs are proving a serious bar to the construction program which the Southern Power Company had planned for this and succeeding years, and that because of these increased prices the program may be indefinitely delayed. While no Southern Power Company official is willing to be quoted to this effect at this time, there is thought to be no doubt of the correctness of the statement. The company finds that rates as they now are and construction costs as they now are eliminate any possibility of a dividend from new construction, and without dividends reasonably in sight it cannot secure money for building.

As readers of the Electrical World have been informed, the company now has under construction two great hydro-electric plants, one at Mountain Island, near Mount Holly, N. C., to develop 80,000 hp., and one at Great Falls, S. C., to develop 60,000 hp. The Great Falls plant, where it was only necessary to build a power house, the company already having a dam, will soon be completed, and the Mountain Island plant will be completed during the present year. In addition the company is building two 10,000-hp. auxiliary steam plants, one at Mount Holly and one at Eno. About two hundred miles of transmission lines and the necessary substation equipment are also being built. The power demand is now away ahead of the supply which the company is able to furnish, and while it is true that the company will soon have an additional 100,000 hp., that was all contracted for many months ago.

### Construction Prices Soar

The company's engineers have for months been figuring on possible sites for new development, the effort being to find where the most power could be developed for the least money. The engineers finally settled on a 50,000-hp. site on the Catawba near Rhodhiss. It has developed during the last few days, however, that at present costs of labor, material and hydraulic and electrical equipment it may be impossible to develop even this site because the income from the power that would be produced would not take care of the investment. Engineers and construction men have recently declared that the contracts for the Mountain Island plant and the Dearborn plant at Great Falls, let about Dec. 1, 1922, were at figures about 25 per cent or more under the present level of prices.

The public has been keenly interested in the prospective further development of the Southern Power Company, not only because of the large investment directly entailed but because of its far-reaching effects on the industrial development of the Carolinas.

## Electrical Men Speak

**Britton and Ballard Address Pacific Coast Meeting of A. S. M. E. on Utility Questions**

JOHN A. BRITTON, first vice-president and general manager of the Pacific Gas & Electric Company, acting as toastmaster at the banquet of the first Pacific Coast regional convention of the American Society of Mechanical Engineers in Los Angeles on the evening of April 18, struck the keynote of the sessions when he urged upon his hearers the necessity of their becoming more familiar with questions of public policy affecting present-day utilities. The proper and delicate handling of these matters, he said, made the continued services of the mechanical engineering profession profitable to its members and useful in the upbuilding of the nation.

J. L. Harrington, president of the A. S. M. E., alluded to the fact that a century ago 90 per cent of the population of America followed agricultural pursuits, while today only 30 per cent of our population is so engaged. He urged the engineer to contribute in larger part to the running of government. Ira N. Hollis, past-president of the society, alluded to the necessity of solidarity in engineering effort. H. M. Robinson, president of the First National Bank of Los Angeles, declared that within the next three years San Francisco and Los Angeles will see in full production the local manufacture of pig iron and steel.

### How One-Tenth Cent May Mean Much

R. H. Ballard, vice-president and general manager of the Southern California Edison Company, impressed upon his audience the fact that in those sections of America where strong, prosperous public utilities prevail the most prosperous communities are to be found. He showed how delicately the whole fabric of utility prosperity is interwoven with slight changes of rates when he brought out that in California a difference of one-tenth of a cent per kilowatt-hour would make a difference of 5 per cent in the surplus of earnings and thus assure the continued prosperity of a utility.

William Mulholland, chief engineer of the Los Angeles Bureau of Light and Power, paid a tribute to the genius of the engineer. Robert Sibley, Pacific Coast consultant for the McGraw-Hill Company and vice-president of the A. S. M. E., in speaking of the industrial and electrical West, pointed to the necessity of breaking the deadlock in the proposed development of the Colorado caused by the failure of the Arizona Legislature to approve the interstate compact and urged that pressure be brought to bear to get action, to the end that the present generation might receive some of the benefits that must accrue from this great storehouse of hydro-electric energy.

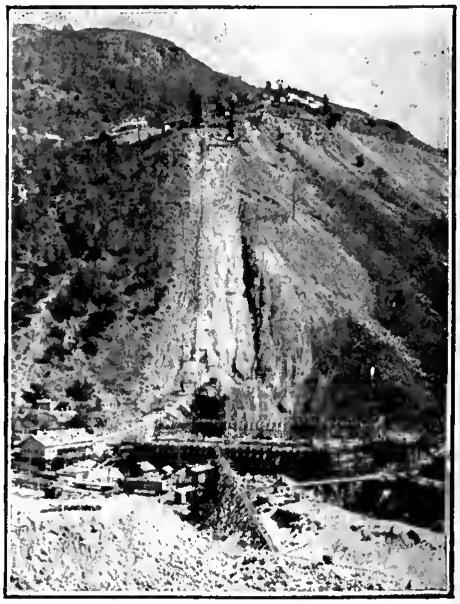
There were about two hundred engineers in attendance at the three-day sessions, many of them being from Eastern manufacturing centers and making their first visit to the West.

# Fourth Plant on Big Creek Started

**Southern California Edison Company Begins Work on the Superstructure of Power House—Eventual Rating to Be 210,000 Hp.—Operation in the Fall Expected**

WORK on the superstructure of the fourth power house on the Southern California Edison Company's Big Creek project, known as Big Creek plant No. 3, which will have a larger generating capacity than any other hydro-electric plant in the West, was started by the company on April 12. The completion of this plant will be the consummation of the fourth step in the Edison company's Big Creek project, which contemplates the development of 1,400,000 hp. from the watercourses of the high Sierra Mountains in central California, at a cost of $375,000,000. The company's budget for 1923 is $26,000,000, which includes, besides the work on the Big Creek project, large expenditures for transmission lines, distribution lines, substations and other construction. More than four thousand men are now engaged on the various phases of the Big Creek project.

The initial installation in this new plant will consist of three 35,000-hp. units, which is one-half of its ultimate development. These will be vertical turbines, built by the Wellman-Seaver-Morgan Company, operating at a speed of 423 r.p.m. and under a head of 760 ft. The generators, which are being built by the Westinghouse Electric & Manufacturing Company, will be rated at 25,000 kva., 11,000 volts, 50 cycles, and will have direct-connected exciters. The building will be 200 ft. long, 139 ft. wide and 110 ft. high from the tailrace floor to the roof and will be of reinforced concrete and structural steel. A feature of the design of the building is the elimination of the basement in the generator room. As the plant is laid out, the operating floor will be on two levels, one at the base of the generators and the other at the elevation of the turbines, so that virtually all of the equipment will be in view of the operator at all times. The switching station will be 195 ft. wide and 430 ft. long and will consist of a series of concrete benches placed on the slope of the mountain, there being a difference in elevation of 46 ft. between the upper and lower benches. These benches will support the 220,000-volt transformers, oil switches and bus.



CONSTRUCTION WORK ON CALIFORNIA EDISON COMPANY'S BIG CREEK NO. 3 PLANT WILL REQUIRE ONLY 141 DAYS

Water will be diverted from the San Joaquin River at a point 6 miles above the power house and just below the tailrace of Big Creek plant No. 8, and conveyed through a 6-mile tunnel having a bore of 21 ft. The tunnel, excavated from solid granite, will be unlined throughout except for one or two places where bad ground was encountered. It will have a capacity of 3,000 second-feet. The excavation is being done by air-operated steam shovels adapted to work in a 21-ft. bore. The muck is being removed by combination trolley and storage-battery type locomotives. Work on this tunnel is now nearly completed.

The penstocks will be made entirely o lap-welded pipe, varying in diameter from 7½ ft. to 6 ft. The valves at the bottom will be of the needle type, and those at the upper ends of the penstocks will be butterfly valves controlled from the power house. At the upper end of the penstocks a surge tank excavated from solid rock will be installed. It will have a shape similar to an hourglass, the largest portion being about 75 ft. in diameter.

The first generating unit in the new plant will be placed in operation about Aug. 1 and will be followed by the second unit about Sept. 1, and it is expected that the entire plant will be completed and the power placed on the lines about Oct. 1 of this year. The power will be transmitted a distance of 240 miles over the first commercially operated 220,000-volt transmission line in the world.

Construction work is now under way on the 13-mile tunnel connecting Lake Florence and Lake Huntington, and with the completion of this tunnel the great watersheds of the High Sierras, having an area about the size of the Hawaiian Islands, will be tapped and the water utilized for an ultimate development of 1,400,000 hp., with a total head of more than two miles.

## Innocent New York Officials Ask About Superpower

The Water Power Commission of the State of New York apparently is not familiar with the superpower survey of the Boston-Washington area made by the United States Geological Survey. Recently the Governor of New York was asked by the Federated American Engineering Societies if his power-development policies would conflict with the superpower plan. Governor Smith referred the letter to the Water Power Commission, which, in replying, said: "Inasmuch as you have not stated how your so-called 'superpower system' is to be carried out and its sources of power, it is impossible to say whether same would be in conflict with the Governor's policies. Would be pleased to have you advise us more fully of the real plan of the superpower system."

With regard to Governor Smith's ideas as to the handling of power development, the letter reads:

"The policy of the Governor relative to power development in behalf of the State of New York is well known in this state. His message to the Legislature declares in effect that the undeveloped water power on the Niagara and St. Lawrence should be developed by the state, that the base power available therefrom should be transmitted to the various municipalities over lines state-owned and controlled, that the electricity so generated be sold to the municipalities at approximately the cost of production and delivery, that the final distribution to the ultimate consumer be made through the agency of the municipality, through existing companies, or by the municipalities, subject to the approval of a state hydro-electric commission as to rates and service."

## Electrical Men Competing in Electrified Homes

Members of the New York Electrical League held a voting contest at a regular meeting on Tuesday of this week to determine which one of them lives in the most completely electrified home. The purpose of the contest was to develop a wider interest locally in the idea that electrical men themselves should lead the community in the completeness with which their homes are wired and the number of appliances which they use.

A special schedule crediting an appropriate number of points to various classes of wiring outlets and to all types of household appliances has been developed as a basis for such contests in the interests of the so-called "Electrify Club," which has been promoted by R. S. Hale, chairman of the N. E. L. A. wiring committee. Copies of this schedule were mailed to all members of the New York Electrical League in advance, and all members and guests at the meeting were invited to make reports on their home equipment and compete for the several prizes offered.

An electric coffee urn, with cream jug, sugar bowl and tray, was contributed by the Edison Electric Appliance Company; *Electrical Merchandising* offered an electric waffle iron, the Illuminating Glassware Guild a portable lamp, the General Electric Company an electric fan, the Simplex Electric Heating Company and the Western Electric Company electric flatirons, and the Westinghouse Electric & Manufacturing Company a tumbler immersion heater.

The highest score turned in was that of Clarence Law of the New York Edison Company, with 227 points. F. S. Montgomery of Wynkoop, Hallenbeck & Company followed with 216 points. A. Lincoln Bush, president of the New York Electrical Contractors' Association, was third with 195 points. Walter Neumuller, New York Edison Company, had 193 points; H. M. Walter, electrical contractor-dealer, 172 points; Roger Williams, Simplex Electric Heating Company, 157 points; F. S. Hartman, General Electric Company 146 points, and Albert Goldman, New York Edison Company, 145 points.

## "Tri-State" Changes Name

**Four Other Commonwealths Join It and Make Up the Southeastern Water and Light Association**

AT THE annual convention of the Tri-State Water and Light Association, held in Birmingham, April 17, 18 and 19, the name of the association was changed to the Southeastern Water and Light Association, and Alabama, Tennessee, Mississippi and Florida were added to the constituent states, which formerly included only Georgia and North and South Carolina.

The convention was given over largely to waterworks and piping, but on Tuesday E. T. Austin, General Electric Company, Atlanta, discussed the development of street lighting, and on Wednesday L. V. Gaffney of the Gaffney (S. C.) electric plant spoke on "Increasing the Day Load." On Thursday the delegates made a visit to the plant of the Alabama Power Company at Lock 12 and to Mitchell Dam, under construction on the Coosa River. Other visits were made to manufacturing plants in Birmingham. Following a banquet Thursday night at the Tutwiler Hotel, "The Power Factor: What It Means to the Central Station," was one among other subjects discussed by the delegates.

### Officers Elected

J. E. Gibson of Charleston, S. C., was re-elected for the third term as president. The following were elected as vice-presidents: D. L. Caston, Gainesville, Ga.; E. M. Foster, Greenville, Miss.; R. O. Polglaze, Gadsden, Ala.; I. S. Robinson, Columbia, Tenn.; Frank Schnabel, Clearwater, Fla., and C. L. Korner, Charlotte, N. C. W. F. Stieglitz of Columbia, S. C., was elected secretary and treasurer for the ninth consecutive time.

The selection of the place for holding the next convention was left to the executive committee. More than one hundred engineers, publicity utility managers and makers of machinery attended.

## Date for Iron and Steel Exposition Set

Sept. 24 to Sept. 28 has been selected as the time for the Iron and Steel Exposition to be held under the auspices of the Association of Iron and Steel Electrical Engineers in the Broadway Auditorium, Buffalo. This building will seat twelve thousand people. The main exhibition floor has 50,000 sq.ft., which will be devoted exclusively to display of apparatus used in the iron and steel industry, and this space is rapidly being reserved by the manufacturers who supply the millions of dollars' worth of steel-mill equipment purchased each year. More than three thousand industrial establishments alone in the vicinity of Buffalo will co-operate in making the exposition a highly specialized form of education.

## Promptness the Keynote

### N. E. L. A. Plans to "Pull Off" Its June Convention at New York City Right on Schedule

PROMPTNESS is to be an outstanding characteristic of the forty-sixth convention of the National Electric Light Association, to be held in New York City at the Hotel Commodore during the five-day period from Monday, June 4, to Friday, June 8, inclusive, and the hours given in the following paragraphs mean "sharp" time, according to the "General Convention Circular" just issued from headquarters.

The general and executive sessions will be held on the mornings of Tuesday, Wednesday, Thursday and Friday, 9.30 a.m., adjourning about 1 p.m. These four sessions will be held in the main ballroom of the hotel. There will be no meetings held in parallel with them.

The public policy committee session will be held on Thursday at 9 p.m. in Carnegie Hall, Seventh Avenue and Fifty-seventh Street. It is planned to broadcast this session by radio.

The customer-ownership committee session will be held on Thursday at 2:15 p.m., at the Hotel Commodore.

The Accounting National Section sessions will be held on Monday, Tuesday, Wednesday and Thursday at 2.15 p.m., adjourning about 5.30 p.m. All four sessions will be held in the music room, Hotel Biltmore, immediately adjacent to the Hotel Commodore.

The Commercial National Section sessions will be held on Monday, Tuesday, Wednesday and Thursday at 2.15 p.m., adjourning about 5.30 p.m. All four sessions will be held at the Hotel Commodore.

The Public Relations National Section sessions will be held on Monday, Tuesday and Wednesday at 2.15 p.m., adjourning about 5.30 p.m. All three sessions of this section will be held at the Hotel Commodore.

The Technical National Section sessions will be held on Monday, Tuesday, Wednesday and Thursday at 2.15 p.m., adjourning about 5.30 p.m. All four sessions will be held at the Hotel Commodore.

The president's reception will take place on Monday evening at the Hotel Commodore. There will be entertainment on Tuesday and Wednesday evenings. Automobile and sight-seeing trips and other forms of diversion will be provided for the ladies attending the convention.

All delegates who have not engaged transportation and made their hotel reservations should do so at once.

## Commonwealth Edison Orders 60,000-Kw. Generator

For its new Crawford Avenue power house the Commonwealth Edison Company of Chicago has just placed with the General Electric Company an order for a 60,000-kw. cross-compound steam-turbine generating unit, the largest generator ever purchased by the Chicago company and equal in rating to any yet manufactured. This is the third generating unit ordered by the Commonwealth Edison Company for its Crawford Avenue station. As previously reported by the ELECTRICAL WORLD, it has an order from C. A. Parsons & Company of England a 40,000-kw. unit and from the Westinghouse Electric & Manufacturing Company one of 50,000 kw. rating. The Crawford Avenue station is to have an ultimate capacity of from 400,000 kw. to 600,000 kw.

# No Action Taken on Colorado Projects

### Following Decision of Cabinet, Federal Power Commission Refuses to Issue License for Diamond Creek Now—Arizona Resents Coercion from Washington

DISCUSSION of the Girand project at Diamond Creek on the Colorado River at the Cabinet meeting on April 20 resulted in a decision that no action should be taken at this time on the application for a license. This led the Federal Power Commission, at a meeting on April 23, to deny the plea of Mr. Girand for immediate action. It had been pointed out to the Cabinet officers composing the Federal Power Commission by the members of the commission's staff that all provisions in the Colorado River compact could be made conditions in any license issued for the Diamond Creek development. The action was taken with full knowledge that the Arizona Legislature while in session had telegraphed the commission protesting vigorously against withholding action on the Girand application and stating that any such action on the part of the Federal Power Commission would be regarded as an intolerable effort to coerce a sovereign state.

#### Girand Project Goes Over

The Federal Power Commission first took up the discussion of its Colorado River policy at a meeting on April 19. At that meeting L. Ward Bannister, an attorney representng the Governor of Colorado, told the commission that Colorado is radically opposed to the granting of the Girand license until the Colorado River compact shall have been ratified. He expressed Colorado's opposition to any more interstate litigation and declared that the doctrine of an equitable division of water on which the compact was based is much sounder than the doctrine of prior appropriation of water. Senator Kendrick of Wyoming told the Commission that more money had been spent in lawyers' fees than in project works and urged that no chance be taken in granting the Girand license. Senator Cameron of Arizona, strangely enough, also opposed the Girand project on the ground that Arizona would be more greatly benefited by the Stetson project, providing for a 1,200-ft. dam at Boulder Canyon, which would flood out completely the proposed Diamond Creek dam.

Members of the Federal Power Commission's staff made it very clear that in their opinion the only valid argument against granting the Girand license is that the delay holds a club over Arizona. They do not share the optimistic opinion expressed in some quarters that a special session of the Arizona Legislature will be called and the compact ratified promptly. Fear is expressed, on the contrary, that the probability of another long delay will be very discouraging to the financial interests which were prepared to pour nearly $100,000,000 into the Diamond Creek development.

## Abilene (Tex.) Has Model Ice and Electric Plant

A new ice and electric plant at Abilene, Tex., built along model lines to replace one destroyed by fire in the spring of 1919, has recently been put into operation by the Abilene Gas & Electric Company. The electric station serves Abilene and twenty-seven other communities by a system of high-tension transmission lines extending in four directions over a territory of 286 square miles. The company has 8,600 customers, and the connected load is 10,000 kw., about equally divided between lighting and power. The territory served is building up rapidly, and work on an extension to three more towns has been begun.

The building is of reinforced-concrete and hollow-tile construction. The generating equipment consists of two units, the first being a Westinghouse 2,500-kva. turbine-generator with a direct-connected exciter and the second a General Electric 1,250-kva. turbine alternator with the exciter independent and motor-driven. As a reserve unit a steam-driven General Electric exciter is provided. Energy is generated at 4,150 volts and is distributed through eight feeder circuits. From a 33,000-volt switching structure, provided with remote-control oil circuit breakers and metering equipment, transmission lines extend north, east, south and west. The switchboard was built by the Westinghouse company.

The boiler plant consists of three 414-hp. Stirling boilers, two of which are arranged in one battery with the third forming a half battery but so arranged that the installation of another boiler will complete it. These boilers are equipped with Babcock & Wilcox superheaters for 150 deg. of superheat, and the plant carries a steam pressure of 200 lb. The boilers are equipped with Duquesne burners of the combination oil and gas type. Water is obtained either from the city's supply or by gravity from a lake which is located near by.

In the engine room there are two York ammonia compressors of 75-ton and 40-ton capacity. To each of the machines is connected a York uniflow steam engine which operates condensing. The condensing equipment is a 1,000-sq.ft. condenser, with motor-driven air and condensate pump and motor-driven circulating water and booster pumps. A natural-draft cooling tower with spray nozzles in the upper section is provided. Water for ice making is taken from the condensate of the ice-machine engines and the turbines of the electric plant and is boiled in a vacuum-type reboiler.

## Brief News Notes

**Progress in Guatemala City.**—A contract recently signed on behalf of the government of Guatemala gives authority to concessionaires to acquire hydro-electric rights and distribute light, heat and power in the capital city for a period of thirty-five years, U. S. Consul A. C. Frost reports. An electric belt-line street-car system will replace the present mule-drawn cars.

**Oskaloosa Will Not Build Municipal Plant.**—Rates for electrical energy for both light and power will drop 40 per cent in Oskaloosa, Iowa, as the result of the action of the City Council in accepting an offer made by the McKinley interests, owners of the Oskaloosa Traction & Light Company. Because of this reduction of rates the city will not build the municipal plant for which a bond issue of $370,000 was recently voted.

**Albuquerque Utility Gets Long-Term Franchise.**—By a close vote the City Commissioners of Albuquerque, N. M., have granted to the Albuquerque Gas & Electric Company a twenty-five-year extension of its present franchise, the company having agreed to make a reduction to all users amounting to 1 cent a kilowatt-hour on the residential rate and ½ cent on the power rate. The company has 4,985 consumers of energy on its books.

**Electric Truck Show in N. E. L. A. Convention Week.**—The annual New York electric truck show, to be held during the week of June 4 in the Irving Place showroom of the New York Edison Company, will include exhibits by all the manufacturers represented in the metropolitan territory. This is the week of the annual convention of the National Electric Light Association, which will devote a session to discussing the electric truck.

**Carnegie Summer Courses.**—Courses to interest nearly any one in need of technical training will be given this summer at Carnegie Institute of Technology, at Pittsburgh, according to a preliminary announcement. Of special interest to electrical students are the courses offered in the College of Industries, which will include elementary electric wiring, advanced electric wiring, elementary principles of electricity and direct-current machinery.

**Electricity from Nature's Steam.**—The development of electric power from steam generated in the earth by nature will be a reality in the near future if the Geysers Development Company is successful in its efforts to harness the steam. One well has been bored and capped and, according to estimates of engineers, there is sufficient steam to generate 2,000 hp. of electricity. About $35,000 has been subscribed by residents of Healdsburg, Cal., a town near the geysers. In Italy steam from the earth has been successfully used for generating electricity for some years.

**Quebec Fights Speculation in Water-Power Sites.**—Quebec is determined, reports from that province indicate, to put an end to the withholding from development for speculative reasons of the province's water-power resources. Honoré Mercier, the Minister of Lands and Forests, is urging that leases shall contain specific requirements as to the program of development. In this he has the backing, it is declared, of a strong public opinion which is opposed to the retention of natural resources by those who are not disposed to develop them. It is estimated officially that Quebec has 6,915,244 hp. of primary hydraulic power and 11,640,052 hp. of power which could be utilized for at least six months of the year.

**Radio Medical Service for Seamen.**—A year ago the United States Public Health Service announced that it had completed arrangements to expand the medical aid service to American seamen with which it had first been charged by Congress a century and a quarter ago by prescribing by radio for any sailor who might be taken ill at sea and who might apply. Messages for aid were to be forwarded to the service by the ship's radio. It is now reported that the range of diseases and mishaps for which aid has been invoked during the first year has been amazing, extending from appendicitis to hiccoughs and the swallowing of broken glass. The Public Health Service physicians at hospitals ashore prescribe treatment by radio with the knowledge that the drugs they specify are probably in stock on the vessel.

**New York Edison Lectures on Trucks Score Big Success.**—The course of lectures for electric truck owners, operators and garage attendants held under the auspices of the New York Edison Company, which came to an end on April 12, proved so successful that plans are already under way for its repetition next year. It was said to be the first attempt that had ever been made to give a systematic course of instruction in the principles of the electric truck, and those enrolled, representing many New York business houses, included both employer and employee. When the course was planned and a fee of a dollar was announced, it was hoped that at least twenty-five and possibly forty could be enrolled. But the enrollment exceeded three hundred in spite of every effort to hold it down. Some of the classes were so large that the lectures had to be repeated.

**Monticello, Ind., Has Largest Hydro-Electric Plant in State.**—Negotiations for the sale of the electric plants at Monon, Francesville and Medaryville, Ind., owned by the Continental Utilities Company of Michigan, to the Interstate Public Service Company for $90,000 have been completed. The Interstate company has been supplying these distribution plants with power from the hydro-electric power plant constructed at Monticello by the Indiana Hydro-Electric Company, which the Interstate Company operates. The new Monticello plant is the largest hydro-electric development in Indiana. It will provide 10,000 hp. daily for light and power, serving at least twenty-five cities and towns in the northern part of the state. The Interstate company is completing a transmission line from Monticello to Logansport, connecting with the Indiana Service Corporation, and it already has a line connecting near Kentland with the Central Illinois Utilities Company, carrying power into Illinois.

**Federal Government Asked to Start Safety Program.**—The United States government sanctions working conditions that would not be tolerated by private employers, it is declared by the Federated American Engineering Societies, which appeal for a federal safety program. Congress is asked to enact safety legislation providing for the safe construction and equipment of buildings, regular inspection of conditions and the training of employees to observe proper precautions against accident. "The government should in its industrial plants set an example to private employers by providing for its own employees working conditions which are safe, hygienic and sanitary," says the statement issued by the federation and prepared by Morton G. Lloyd. The federation also recommends the adoption by the several states of uniform legislation aiming at the creation of administrative officials who shall have power to make and to enforce regulations for the prevention of accidents and industrial diseases.

**Electric Drive in the Golden Gate.**—Three electrically driven vessels recently received trial trips at San Francisco. Two of these were ferryboats and the other was an oil tanker. The latter is the first electrically driven tanker ever constructed. Its equipment includes two 750-hp. Pacific Diesel engines, two General Electric marine-type generators and two General Electric marine-type motors connected to the same propeller shaft. The ferryboat Hayward was built for the San Francisco-Oakland Terminal Railways and will be used in the passenger service on San Francisco Bay. The propelling equipment consists of a Curtis turbo-generator set, rated at 1,100 kw., with direct-connected exciter. Each of the two propellers is driven by a 1,200-hp. General Electric marine-type motor. The ferryboat Golden West is a sister ship to the Golden Gate, which has

been in operation on San Francisco Bay for some time. It is driven by two Pacific Diesel engines with General Electric generators and two marine-type General Electric motors, one on each propeller.

**Survey of Colorado River to Go On.**—The deep and narrow gorges of the Marble and Grand Canyons, said to be the most treacherous in the world, will be surveyed by a party of engineers and geologists of the Department of the Interior this summer, when a complete group of maps will be made of the Colorado River for a distance of 300 miles from Lee's Ferry to Grand Wash, Ariz. A program of special stream surveys, showing the plan and profile of streams with sufficient topography to cover all possible locations for structures needed in a comprehensive scheme of water development, was initiated in the Colorado River basin in 1909. An aggregate of about 1,200 miles on Colorado and Green Rivers and several hundred miles on principal tributaries had been mapped by the end of 1922. There are now available, with the exception of the stretch of about 300 miles to be surveyed this year, maps of a continuous river survey from the town of Green River, Wyo., on the Green River, and from Grand Junction, Col., on the Colorado River, to the Mexican boundary. This year's exploration party will consist of ten men, including two topographic engineers, one hydraulic engineer and one geologist. Detailed examinations of possible dam sites, both from an engineering and a geological point of view, will be made.

**Salt Lake Holds Electrical Convention.**—At the second annual convention of the electrical interests of Salt Lake City and the adjacent territory, held on April 6 at the Hotel Utah, Salt Lake City, under the auspices of the Rocky Mountain Electrical Co-operative League, approximately a hundred members, representing various branches of the industry, were in attendance. Sidney W. Bishop, the executive manager of the league, outlined its many activities, and the "get together" spirit prevailed.

# Associations and Societies

**New England Division, N. E. L. A.**—The New England Geographic Division of the National Electric Light Association will hold its next convention at Swampscott, Mass., on Sept. 6-8.

**Iowa Section, N. E. L. A.**—The annual convention of the Iowa Section, N. E. L. A., and the Iowa Electric Railway Association will be held at the Hotel Hanford, Mason City, Iowa, on June 20, 21 and 22.

**Pacific Coast Electrical Association.**—Plans for the seventh annual convention of the Pacific Coast Electrical Association, to be held in San Francisco June 19-23, have been put into shape. The opening day will be devoted to registration, and in the evening motion pictures will be presented. On June 20 James B. Black will give the president's address. Technical and Commercial Section meetings will be held in the afternoon and continued on the morning of June 21. The second business session will be held on the next morning, and the Western conference is scheduled for the afternoon with the banquet in the evening. On Saturday the delegates will take a trip up Mount Tamalpais and into Muir Woods.

**American Electrochemical Society.**—When this society assembles at the Commodore Hotel, New York, on Thursday, May 3, there will be a session devoted to reading and discussing seven papers on electrode potentials. Papers on electrodeposition will follow in the afternoon. On Friday, among other papers, will be "Heat-Insulating Material for Electrically Heated Apparatus," by J. C. Woodson; "Methods of Handling Materials in the Electric Furnace and the Best Type of Furnace to Use," by Frank W. Brooke; "Relation Between Current, Voltage and the Length of the Carbon Arcs," by A. E. R. Westman, and "Electric Furnace Detinning and Production of Synthetic Gray Iron from Tinplate Scrap," by C. E. Williams, C. E. Sims and C. A. Newhall. "Production and Application of the Rarer Metals" will be general subject of eight papers on Saturday.

### Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

American Electrochemical Society — New York, May 3-5. Colin G. Fink, Columbia University, New York.

Nebraska Section, N. E. L. A.—Omaha, May 10-11. Horace M. Davis, Lincoln.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

Empire State Gas and Electric Association, Electric Section—Utica, N. Y., May 17-18. C. H. B. Chapin, Grand Central Terminal, New York.

Electrical Supply Jobbers' Association—Executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

Missouri Association of Public Utilities—River boat from St. Louis to Peoria, May 24-26.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

California State Association of Electrical Contractors and Dealers—Dorner Lake, Cal., June 9-16.

Electric Power Club — Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

North Central Division, N. E. L. A.—Minneapolis, June 13-15. H. E. Young, Minneapolis General Electric Company.

Pacific Coast Electrical Association—San Francisco, June 19-23. S. H. Taylor, 527 Rialto Bldg., San Francisco.

Society for the Promotion of Engineering Education—Ithaca, N. Y., June 20-22. F. L. Bishop, University of Pittsburgh.

Canadian Electrical Association — Montreal, June 20-23. Louis Kon, 65 McGill College Ave., Montreal.

American Institute of Electrical Engineers—Annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

American Society for Testing Materials—Atlantic City, June 25-29.

Associated Manufacturers of Electrical Supplies—New London, Conn., June 26-29. Frederic Nicholas, 30 East 42d St., New York.

National Council Lighting Fixture Manufacturers—Buffalo, June 26-28. C. H. Hofrichter, 233 Gordon Square Bldg., Cleveland.

Northwest Electric Light and Power Association—Seattle, June 27-30. G. E. Quinan, 204 Electric Bldg., Seattle.

Ohio Electric Light Association — Cedar Point, July 10-13. D. L. Gaskill, Greenville.

ROCKY MOUNTAIN ELECTRICAL MEN GATHER AT SALT LAKE CITY

## Recent Court Decisions

**Assumption of Risk in Pole Climbing.**—The District Court of Appeal of California found, in Richardson vs. Southern Pacific Company, that where the plaintiff, an experienced telegraph lineman, ordered to ascend a pole, called his foreman's attention to surface rot at the foot of the pole, but the foreman assured him that the pole was all right, and plaintiff was injured by the breaking of the pole, plaintiff had not assumed the risk as a matter of law and the question of contributory negligence was one for the jury. (212 Pac. 959.)*

**Hearings Under Florida Commission Law.**—The United States District Court at Jacksonville, Fla., found, in Jacksonville Gas Company vs. City of Jacksonville, that the act providing for the fixing of rates by the City Commission of Jacksonville, and for appeal to the Railroad Commission, did not deny the company due process of law in violation of the Fourteenth Amendment, in according no hearing to the company, inasmuch as the company had the prescribed notice and had opportunity to appeal to the Railroad Commission, where it could have had a hearing. (286 Fed. 404.)

**Public Interest in Preventing Bankruptcy of Utility.**—Dismissing injunctions found in the lower court, the Court of Appeals of Kentucky found, in Stafford vs. Johnson County Gas Company, that where it appeared that a utility company was losing money and could probably not continue to operate, or would be forced into bankruptcy, if the rates were not increased, the interest of the public in continuance of the service was a good and valid consideration for the enactment by the board of trustees of the town of Paintsville of ordinances amending the franchise so as to permit the company to charge increased rates. (248 S. W. 515.)

**Evidence of Negligence Justifying Submittal of Damage Suit to Jury.**—Sustaining a verdict of $10,000 damages in Graham vs. City of Ames for the death of a young man who came in contact with a broken transmission wire of the municipal plant and was killed in an alleyway while delivering papers in the early morning, the Supreme Court of Iowa held that the lower court did right in refusing a directed verdict. Three grounds for the charge of negligence against the city were submitted to the jury, rightly as the Supreme Court held: (1) That the defendant had constructed its line out of inefficient material and that it was inadequate for the service required; (2) that the defendant had failed to use diligence either to repair the broken wire or to shut off the current therefrom; (3) that the defendant had failed to equip its plant with suitable devices to enable it to discover promptly a break in its primary wires. The contention that pedestrians had no right to use alleys as a path was overruled. The presumption, in the absence of any eye witness to the accident, was that the victim used due care. (192 N. W. 299.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

**Powers of West Virginia Commission.**—In Berkeley Springs Waterworks vs. Public Service Commission of West Virginia, an experimental order of the commission valuing the plant of, and fixing the rates to be charged by, a public utility, and retaining the case on the docket for future report and action after the results of such experiment are ascertained, was not final, according to the ruling of the Supreme Court of Appeals of West Virginia, and an appeal therefrom to the court was dismissed, without prejudice to further action thereon by the commission. (116 S. E. 140.)

## Commission Rulings

**Special Rate for Surplus Power Supplied to One Customer Only Cannot Be Granted.**—The Wisconsin Railroad Commission has refused to allow a special surplus power rate to be made to the Dells Paper & Pulp Company of Eau Claire, on the ground that such a rate cannot be granted where only a single customer would benefit.

**Historical-Cost Valuation Method Defended.**—The New Hampshire Public Service Commission in investigating the rates of the Exeter Water Works declared its belief that the historical cost of a plant is always more satisfactory as a measure of value than the reproduction cost, since the first is based upon facts while the latter is based upon estimates which at most are only intelligent guesses; but, the commission added, the enhanced value due to present prices must receive due consideration.

**Free Service for Right-of-Way Illegal.**—Free service as part of the consideration for a right-of-way is unlawful, according to a decision of the Pennsylvania Public Service Commission in complaints made against the Manufacturers' Light & Heat Company. It held that the facts that the grantor in the contract was an individual instead of a municipal corporation and that the thing granted in consideration of the free service consisted of a right-of-way over private property instead of a municipal franchise on or along public streets did not take the case out of the scope of the legal principle involved in cases where free service to municipalities had been discontinued. The question was also presented whether the public utility while refusing to deliver free service could continue to occupy the right-of-way. The commission stated its opinion that the question raised on this ground was judicial and beyond the scope of the commission's jurisdiction.

**Basis for Overhead Allowance.**—According to a decision of the Vermont Public Service Commission concerning the Rutland Railway, Light & Power Company, a percentage allowance for overhead expense in an estimate of original cost should not be based on the depreciated value of the property. "The services of engineers and superintendents," the commission said, "were rendered upon the original construction; therefore, if the amount to be allowed is computed on a percentage theory, the proper base is original cost and not the value of the property as it might be after years of use."

**City May Intervene in Action to Raise Franchise Rates.**—The New York Public Service Commission held in considering a petition from the Peekskill Lighting & Railway Company to increase fares that the municipality had a right to intervene in an endeavor to maintain the franchise rates. "The reference in the statute to the rate theretofore prescribed by local municipal consent and the requirement that the commission shall regard the estimated earning capacity of the property under that rate show to my mind," said the commissioner who handed down the decision, "that the contract or franchise rate is one that the municipality has a clear right to come in and defend. The rate so fixed by the franchise or contract is, in my opinion, a binding rate until on facts shown to the commission it shall determine that in the public interest a different fare is necessary for the safe and adequate service of the public. On this question and on this proof the municipality has a right to be heard."

**Dividing Line Between Responsibility of Commission and of Company Management.**—In adjusting a complaint made against the Philadelphia Rapid Transit Company, the Pennsylvania Public Service Commission adverted to the danger of a commission infringing on what is properly managerial territory, saying that the commission's duties "are not to be performed by its assuming managerial control over public utilities, nor by substituting its judgment for theirs in the performance of those things for which, for the public benefit, the law holds these utilities responsible. The line of demarcation between the duty of a company to exercise its managerial judgment and the responsibility resting upon this commission to regulate is established where the utility is exercising its initiative responsibility in a way which adversely affects the public. The commission must exercise care that it does not relieve utilities by its orders of a managerial duty which they ought to perform and of a responsibility which, if they are to function properly in public service, must continue to be theirs."

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## D. Farrand and J. L. O'Toole Made Vice-Presidents

Dudley Farrand and John L. O'Toole, assistants to the president of the Public Service Corporation of New Jersey, were elected vice-presidents of the Public Service Corporation of New Jersey at the annual meeting on April 18 of the directors of the company and twelve subsidiaries. Mr. O'Toole became connected with the Public Service Corporation in 1909, after having been in newspaper work in Newark for seventeen years. For nine years prior to becoming publicity agent for the corporation he was city editor of the Newark *News*. In 1917 his title was changed from publicity agent to assistant to the president. Mr. Farrand has been with the predecessors of the Public Service Electric Company and with the corporation continuously since 1887. He was first elected a director and assistant treasurer of the Newark Electric Light & Power Company. In 1895 he became assistant general manager of the People's Light & Power Company and three years later its general manager.

The following year Mr. Farrand became general manager of the United Electric Company of New Jersey and in 1903, the year of reorganization, he was made general manager of the electric department of the Public Service Corporation. In 1910 Mr. Farrand was made general manager of the Public Service Electric Company and five years later was made its vice-president and general manager. In 1917 he also was made assistant to the president. Mr. Farrand was president of the National Electric Light Association in 1907 and the following year was appointed by President Roosevelt as technical adviser representing the electrical interests to the National Conservation Commission.

The election of Messrs. O'Toole and Farrand was announced with other important changes in the staff of officers of the Public Service Corporation. Thomas N. McCarter was re-elected president of the corporation and subsidiaries for the twenty-first consecutive term. Vice-presidents Randell Morgan of Philadelphia and Colonel Anthony R. Kuser of Bernardsville, both of whom have been officials of the company for about fifteen years, resigned. They will continue as members of the board of directors of the corporation and as members of the executive committee.

Under the reorganization plan Percy S. Young is vice-president in charge of finance, Edmund W. Wakelee is vice-president in charge of law, Dudley Farrand vice-president in charge of

DUDLEY FARRAND

industrial relations, and John L. O'Toole vice-president in charge of public relations. Mr. Wakelee, who has been general solicitor as well as a vice-president, has relinquished the first title to George H. Blake, who has been assistant general solicitor. He also will relinquish some of his work as vice-president in charge of public relations to Mr. O'Toole, devoting his entire time to the law.

Mr. Young, as heretofore, will be chief financial officer. The scope of the work of Mr. Farrand as vice-president in charge of industrial relations is wide. He will keep in close touch with the employees of the various subsidiaries and will deal with operating problems. Mr. O'Toole's work will be along the same lines as it has been, together with additional duties to be taken over from Mr. Wakelee.

J. L. O'TOOLE

## R. E. Danforth Heads New Power Company

Richard E. Danforth, vice-president and general manager of the Public Service Railway, Newark, N. J., has been elected president of the Public Service Electric Power Company, a subsidiary of the Public Service Corporation of New Jersey. Mr. Danforth retains his executive position with the railway company. The following officers were also elected: Henry D. Whitcomb, vice-president; William H. Feller, secretary, and Frederick A. Neis, treasurer.

**C. I. Rhodes**, formerly chief of the hydraulic division of the California Railroad Commission, has resigned to become associated with Chester H. Loveland, consulting engineer of San Francisco.

**Joseph Pope** has been transferred from the power-station betterment division of Stone & Webster, Inc., Boston, to steam-power plant research. His former position as head of the betterment division will be filled by Walter H. Balcke.

**R. A. Bruce** has succeeded F. J. L. Doyle as assistant secretary and assistant treasurer of the West Virginia Utilities Company and as auditor and assistant treasurer of the Wheeling Public Service Company, both in Wheeling, W. Va.

**George W. Wood**, formerly manager of the Mansfield (Mass.) Municipal Lighting Department, is now associated with the C. D. Parker Company, bankers, of Boston, who operate the Fibreboard Company, manufacturer of a patented leather-fiber board. Mr. Wood is stationed at the Fibreboard Company's Amesbury plant.

**Henry Trumbower**, member of the Wisconsin Railroad Commission since 1916, has resigned, effective May 1, to accept an appointment with the United States Department of Agriculture in charge of an investigation of the economics of transportation as it relates to marketing and distribution of farm products.

**K. E. Van Kuran**, district manager of the Westinghouse Electric & Manufacturing Company, and **R. E. Fisher**, vice-president of the Pacific Gas & Electric Company, both of San Francisco, have been appointed a committee of two to arrange for transportation to the annual convention of the National Electric Light Association to be held in New York City June 4-8.

**Howard S. Snell** has been appointed chief engineer for the Montana Public Service Commission to fill the vacancy caused by the resignation of James H. Bonner. Mr. Snell goes to the Montana commission with twelve years' experience in public utility work. He was engineer for the Public Service Commission of Kansas for three and one-half years and was consulting engineer for the Kansas City, Mexican & Orient Railway Company. He has had five years' experience in valuation of utility properties.

### W. H. Taylor Made General Manager

W. H. Taylor, vice-president of the Georgia Railway & Power Company, Atlanta, has been appointed general manager of the business of the company. He will be designated as vice-president and general manager and will have general supervision over various departments, assisting H. M. Atkinson, chairman of the board, and P. S. Arkwright, president.

**I. A. Rosok** has succeeded H. B. Johnson as manager of the Bisbee (Ariz.) Improvement Company.

**Kurt C. Barth**, formerly associated with the Barrett Company, which was recently taken over by the Allied Chemical & Dye Stuff Company, has been appointed Eastern manager at Chicago for the E. T. Chapin Company, Spokane, Wash.

**Calvert Townley**, assistant to the president of the Westinghouse Electric & Manufacturing Company, has been re-elected a vice-president of the American Engineering Council and has been appointed a member of its finance and public affairs committees.

**G. H. Froebel**, manager of the Houston (Tex.) branch office of the Westinghouse Electric & Manufacturing Company, has been appointed manager of the marine sales department. Mr. Froebel's headquarters will be at East Pittsburgh.

**R. T. Gordon**, who for the past eight years has been connected with the Alberger Pump & Condenser Company, has resigned to join the sales department of the Dean Brothers Company of Indianapolis, manufacturer of pumping machinery, and will be with its New York office.

**Carl O. Martin**, formerly in charge of the Northwest territory of the Benjamin Electric Manufacturing Company, has been transferred to a larger field with headquarters in San Francisco. There he will be assistant to Miles F. Steel, Pacific Coast manager for the company.

**A. S. Childs** has resigned as sales manager of the Cooper Hewitt Electric Company after twenty years' association with that company. Charles F. Strebig, formerly manager of the Philadelphia office, succeeds Mr. Childs as sales manager. Mr. Strebig has been with the company fifteen years.

**William H. Welch**, formerly manager of the Hartford (Conn.) branch of the Electric Supply & Equipment Company, has been appointed sales manager of the Hartford Electrical Supply Company. M. G. Francoeur has been appointed sales promotion manager of the latter company. E. F. Irlbacker, formerly manager of the fixture department, has resigned from the company.

**Henry D. Jackson**, formerly electrical and mechanical engineer with Monks & Johnson, engineers of New York and Boston, and William P. Mower, his assistant on the mechanical work, are leaving the organization to associate themselves with W. R. Templeton in the manufacture and sale of the "Templeton" return and boiler-feed trap.

**J. H. Klinck** has been appointed assistant supervisor of production of the Westinghouse Electric & Manufacturing Company. Mr. Klinck, who has had wide experience in electrical and general engineering and sales work, has been associated with the Westinghouse company since 1904, when he joined the industrial and power sales department.

### R. Collier Leaves Poughkeepsie

Rawson Collier, general sales manager of the Central Hudson Gas & Electric Company and affiliated companies, with offices at Poughkeepsie, N. Y., has resigned to join the organization of Dwight P. Robinson & Company, Inc., engineers and constructors, New York, on May 1. Prior to his connection with

Rawson Collier

the Central Hudson Gas & Electric Company, Mr. Collier was for five years a member of the firm of Collier & Brown, consulting engineers, Atlanta, leaving this firm to become connected with the Georgia Railway & Electric Company. Here his work covered sixteen years, during which time he was connected with practically every department in the company. At the time of leaving he was general sales manager of the company. Mr. Collier is a graduate of the Massachusetts Institute of Technology, and for a number of years he has been prominently indentified with the work of the National Electric Light Association, the American Institute of Electrical Engineers, the American Gas Association and the Illuminating Engineering Society.

**August Lutz**, Oakland manager of the Pacific States Electric Company, was recently elected president of the Electric Club of Oakland.

**C. H. Kurz**, has been appointed to succeed Dyer Thomas as the manager of the Federal Electric Company in Denver, the latter having been transferred to Detroit as sales manager of the company.

## Obituary

**William F. McNally**, president of the Crookston (Minn.) Water Works, Light & Power Company and of the Manistique (Wis.) Light & Power Company, died recently at his home in New Richmond, Wis., at the age of sixty-three. Mr. McNally's life was largely devoted to the practice of law.

**John Gilbert Ward**, for thirty years treasurer of the Babcock & Wilcox Company, died on Sunday at his home in Glen Ridge, N. J. Mr. Ward entered the treasurer's office of the Babcock & Wilcox Company as a clerk in 1888, later becoming assistant to the treasurer, and in 1893 he was elected treasurer and a director of the company. He was sixty-eight years of age.

**Samuel C. D. Johns**, identified for thirty-five years with the Cleveland Electric Illuminating Company and its predecessor, died on April 20 after a brief illness. Mr. Johns was secretary of the company when he retired in 1918. He was born in England but educated in Cleveland. Previous to his association with the power company he had been a railroader and telegraph operator. Mr. Johns was eighty years of age.

**C. F. Beames**, consulting engineer with the Columbia Gas & Electric Company, New York City, died suddenly on Sunday, April 22. Mr. Beames was at one time connected with the General Electric Company at its Schenectady and Chicago offices and later was sent to Mexico. Subsequently he allied himself with the Mexican Gas & Electric Light Company in Mexico City. Later Mr. Beames became associated with the J. G. White Corporation in Porto Rico and also was connected at one time with the Electric Bond & Share Company. During the war he was lieutenant-colonel in the Ordnance Department, U.S.A.

**Thomas C. Gordon** of Little Falls, Minn., died at his home in that city on April 16 after a year's illness. Mr. Gordon became associated with the Little Falls Water Power Company in 1887. In 1889 he was made secretary-treasurer, and in 1903 the duties of general manager were conferred on him. In 1918 Mr. Gordon disposed of his interests in the water-power company and shortly thereafter engaged in the automobile and garage business. In addition to his duties with the Little Falls Water Power Company and the Gordon Motor Company, he found time to take an interest in many other business ventures. He was instrumental in forming the Morrison County Electric Light, Heat & Power Company, now out of existence, and was its secretary-treasurer. He filled the same office for the Pike Rapids Hydro-Electric Company, which owned and controlled a power site a few miles below the city.

## Pruning the Wiring-Device Line

**How Excess Varieties Are Crippling the Electrical Trade—What One Manufacturer Has Done—Great Promise if Courage Lasts**

By Earl E. Whitehorne
*Commercial Editor* Electrical World

THE other day in the office of a prominent jobber of electrical supplies I saw three piles of inventory cards stacked up in the corner. Each card represented a different item in that jobber's stock. On the card were entered the number of units and the quantity of that commodity in stock at the time of the January inventory. Two of these piles reached a little over three feet up the wall; the other was two feet high. The two big piles represented the articles that were to be continued in stock. The short pile represented obsolete material that was to be thrown out of stock. In short, the obsolete material in that jobber's stock on the first of January had amounted to about one-fifth of his entire line, in number of varieties—say 1,500 items out of a total of 7,500. Because this man is progressive and a firm believer in the present movement for simplification in the jobbing line, he is going to quit selling these obsolete types, although some demand still continues. But Heaven knows how many excess and duplicating varieties he will go on carrying on his shelves. The noose is still around his neck and the manufacturer holds the business end of the rope.

### The Epidemic

The disease with which the electrical jobber has been suffering for a number of years can undoubtedly be diagnosed as congestion of stock—with complications. He caught it from the electrical manufacturer. The electrical manufacturer contracted the disease as the result of a bad habit. He had begun in the early days to manufacture a socket, a receptacle, a conduit fitting, or, say, a fuse, and developed a necessary line. Then people began asking for special stuff. He made it because it seemed to be needed and because it was profitable to make it—which was quite proper. But instead of calling it "special," he made the fatal error of listing and picturing all this special stuff in his catalog as standard. "Watch my line grow!" he said. "I'm getting ahead!" Naturally people saw these new varieties and asked the jobber for them. The jobber began to stock them, but because they were special fittings for unusual needs there were few orders. But this slow-moving stock has grown as every manufacturer in almost every line has madly proceeded with this competition for bigger lines until finally excess varieties began to choke the industry to death.

Jobbing stocks had swollen until one jobbing house at least today is listing over 50,000 items, and catalogs of 12,000 and 20,000 are common. And because they have been smothered under this load of varieties, jobbers, sales managers and salesmen have been demoralized into a class of overburdened order takers. For what man can do creative selling and develop a market for 50,000 articles—or 7,500?

Too many manufacturers have been making too many articles in too small volume. Too many jobbers have been selling too many varieties in too small volume. And to try to get more volume manufacturers have gone on giving opportunity to too many semi-jobbers to compete with established houses. And the jobbers in turn have been selling to anybody to get an order and building up "curbstone" competition for their best contractor customers. And there you are!

### Jobbers Have Decided to Act

But the worm will turn. The burden has grown too heavy for either manufacturer or jobber. So for some time each has been calling on the other to do something toward simplification. "Stop ordering these excess varieties and selling them!" the manufacturer has said. But he has continued to list these varieties and send his catalogs into the jobber's territory.

Therefore the trade has continued to order them and the jobber has gone on selling them. It was inevitable, however, that both parties to the situation should ultimately be compelled to do something to help themselves.

Last February the executive committee of the jobbers' association called upon all its commodity committees to study the opportunities for the elimination of excess, obsolete and duplicating varieties in each line and bring in definite recommendations at the coming meeting of that association in Hot Springs, Va., next month, specifying what the jobber himself should do and what the manufacturer should do. Meanwhile a few manufacturers also have decided to quit discussing it and act. Here is a good example in the wiring-devices line.

### One Manufacturer's Discovery

It was decreed by the executive of one of the largest manufacturers that their line should be reduced. They had listed in their catalog the following articles:

| | |
|---|---|
| 344 | sockets |
| 236 | receptacles |
| 269 | switches |
| 82 | plugs and receptacles |
| 29 | rosettes |
| 421 | cut-outs and fuses |
| 1,381 | devices in all |

When the pencil was sharpened and they went to work, they found that they could eliminate as either obsolete or duplicating or unnecessary excess varieties:

| | |
|---|---|
| 175 | sockets |
| 192 | receptacles |
| 77 | switches |
| 51 | plugs and receptacles |
| 20 | rosettes |
| 107 | cut-outs and fuses |
| 622 | devices in all |

This left in the line as essential:

169 sockets
44 receptacles
192 switches
31 plugs and receptacles
9 rosettes
314 cut-outs and fuses

759 devices in all

Even this was not all. They went back at it again, and when they had analyzed the line once more over 800 numbers had been eliminated. Some were sockets or receptacles or switches that were obsolete. Some were practically duplicates of other numbers. Some were varieties popular in one section but differing only superficially from another number that is in general demand elsewhere. They were all excess varieties. For instance the entire line of standard-depth switches was eliminated, and the standard numbers were given to the shallow switch line. The trade was notified that only shallow switches would be shipped thereafter because shallow switches will do all that the deep ones will do.

### The Economic Loss

A group of jobbers got together and studied the lines of schedule material cataloged by four different manufacturers. They decided that these eliminations could be made:

Manufacturer A-553 varieties
Manufacturer B-350 varieties
Manufacturer C-239 varieties
Manufacturer D-247 varieties

One of these jobbers, who by the way had argued for 100 more eliminations, said: "This means that those manufacturers are listing, advertising, cataloging and keeping forms, castings, patterns, etc., to manufacture these obsolete items whenever demanded. The same thing is true with the jobbers. They carry the articles in stock, where they take up room on shelves that is valuable and costs money; they put them in their catalogs. If they have ten of an item in stock and get an order for ten or fifteen, they order a standard package of possibly as many as 500 to rot on their shelves and increase their overhead. The ultimate consumer could be better served at lower costs if these duplications were eliminated.

"We haven't got very far with the manufacturers themselves," he continued. "They all appear to be afraid of each other, yet you talk to them all individually and personally and they seem to be for it. When you get through talking to them, go home and write them a letter; however, each one comes out and tells you that an ideal result could be accomplished if all would work together, but that he can't do it because he is afraid of the other fellow.

"As I see the proposition, the only thing to do is to arouse a public opinion against these expensive duplications and do away with them, or go down to Washington and demand that the government practice a little paternalism. But I don't believe the government would dabble in a matter of this kind unless the manufacturers compel it by their indifference."

A JOBBER'S INVENTORY—7,500 CARDS

The short pile, 20 per cent of the entire line, represents obsolete varieties which can be eliminated.

### Whose Move Is It?

One manufacturer, in discussing the problem recently, said to me: "The matter can be better handled by the consumer or the distributor than by the manufacturer. The manufacturer must continue to supply any demand. A campaign of general educational work carried on by every one interested can do a great deal by removing the demand. We are always ready to meet our customers or distributors half way." In that attitude, I believe, lies the source of much of the difficulty, but as a matter of actual fact the manufacturer does not meet any demand any more than a street car runs up any street because somebody wants it to. There is always an end to any line and it is the manufacturer who sets the point where the line stops.

The trouble is that he hesitates to take the drastic step, even though he knows that it will save him money on production. To quote a jobber who has thought much on the subject: "Three or four manufacturers can take a decisive step and put it over, whereas 200 distributors pulling this way and that will accomplish nothing. One distributor says that some device is a good seller; another says that it is not. It doesn't matter who is right. The manufacturer for economic reasons can refuse to make it, catalog it or sell it and the deed is done. Both distributors will from then on sell the remaining variety with no less success."

### Only Courage Needed

One manufacturer wrote to me: "There is much to be said for it. However, on the other hand, much against it—etc., etc.," which is a pretty good example of what the general attitude has been in recent years. In the meantime the burden of excess varieties has been getting steadily worse. More refinements and improvements and extensions have been added to the line—every line—and few taken off the market, and, of course, this has been no less the fault of the jobber than the manufacturer. One jobber recently put it in these words: "The manufacturer naturally has objected to eliminating some numbers that have been good sellers with us, for instance. However, we know that many of these items continue to be good sellers here because we do not direct customers to the selection of proper products and they are left to buy at random anything we may show in our catalog."

All this refers not alone to sockets, receptacles and switches. It applies to fuses, to conduit fittings, to insulators, to lamps, to reflectors, to as many other lines as you can count on your two hands. Why should there be both galvanized and black outlet boxes, why both galvanized and black pipe—when galvanized is better and would be cheaper if the product were made in that style only? Why should there be five kinds of heater cord?

The economic principle involved in all of this is unassailable. Any one who does not believe it need but look through any jobber's stock or catalog. The only question is with the individual. Has he the moral courage to act on principle and tell his salesmen and his customers and his suppliers or his distributors that they must stop doing something that is not good for all of them? It is encouraging to see that some manufacturers at last have had the nerve to face the situation and proceed to clean up their own lines and free themselves from the dragging chains with which these excess varieties so long have hobbled them.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

CONTINUED expansion of business characterizes virtually all branches of the electrical trade. Conservative financing and careful buying by manufacturers and jobbers are keeping most sections of the country reasonably free from inflation, and although increasing scarcity of labor is being felt, production is at a high rate and transportation conditions are much improved on railways. Important central-station construction is under way in southern New England, and work is being rapidly pushed on some trunk-line high-voltage interconnections. Wire factories and electrical machinery makers are working close to capacity, and appliance and specialty makers are crowded with orders. Central-station outputs are growing by leaps and bounds. House-wiring developments are in immense volume, and there is little sign of recession in the equipment of old houses or the building of new ones. Here and there industrial-plant expansion is beginning to take on the appearance of war-time plant development. Manufacturing in general is on a full-time basis. The textile industries are working very near capacity and the metal-working establishments are busy caring for past orders, new business being obliged to face a lengthening delivery situation. Retail trade is improving with better weather and easier highway travel. Non-employment is scarcely heard of, and recent wage increases in the textile field appear to have been promptly translated into increased buying of commodities. Electrical appliances are in greater demand, and popular interest in the "electrical home" movement and in better home displays is finding an outlet in growing purchases of electrical labor-saving devices and comforts.

## Irons for Reserve Purposes a Feature of Present Market

SALES of electric flatirons continue to be well maintained and deliveries are reported as very satisfactory. These devices are probably first in popularity after the electric lamp, and the point of local saturation seems as far off as ever in many electrical utility areas. A feature of this spring's business is a tendency toward ordering a duplicate iron or a unit of a second make for reserve purposes in the home. Retailers apparently have not attempted to push irons on this basis to a great extent, and the realization of the convenience of a second outfit in the ordinary home has come largely from satisfied users. New designs in irons are coming into the market this spring and arousing much popular interest. Price conditions appear to have little bearing upon sales developments, and there seems to be a market for American irons of diversified quality and reputation. Some central-station tests of cheaply made and inferior makes of irons, especially of German "extraction," have been a powerful deterrent to the flooding of the American market with unsuitable products.

## Tool Makers Advising Customers to Anticipate Requirements

MANUFACTURERS of electric tools are finding some difficulty in obtaining prompt delivery of certain sizes of steel, which makes it necessary for them to increase their stocks of raw material to provide against delays. Prices on their lines are stiffening, skilled labor is increasingly difficult to obtain, and wages are on the upward trend. These manufacturers are advising their customers to anticipate their requirements as far ahead as possible to avoid disappointments or non-delivery. Makers of belts and safety straps are experiencing considerable difficulty in getting enough leather to keep up with the present unusual demand.

## Electric Refrigerating Outfits Moving Well

CONSIDERABLE activity in manufacturing circles devoted to the production of electrically driven refrigerators is apparent as the warmer season approaches. Interest among central-station power sales departments has begun to quicken as a result of renewed efforts of manufacturers to develop a wider line of equipments suited to more moderate-sized homes than were the large outfits put earlier on the market. New apparatus has lately been brought out with remarkably simple mechanical details in comparison with former designs, and while it would be exaggeration to state that the smaller residence can at present be supplied with refrigeration at low cost from the investment standpoint, the trend of development is in that direction. For many years the development of such equipment centered around hotels, markets, fruit establishments and provision houses; gradually equipments began to appear suited to large residences, and today the outlook is bright for a great advance in electric cooling applications into the field of the medium-sized home. Some of the apparatus available may fairly be said to have settled down to a standard production basis, and as the market widens the costs of development will be absorbed by sales and the development of much smaller machines hastened.

## Heater Sales Reported Dull in New England

SPRING sales of electric heaters for socket attachment have been rather slow during the past few weeks, although the coal situation has cleared only gradually. Distributors and retailers were prepared to handle a considerably larger business than materialized. Weather conditions appear responsible in part for this falling off in demand, there having been few sudden and sharp drops in temperature and more even conditions than usual for this season. In trade circles the opinion is generally held that the fall is the best time to push heaters at retail, but with fuel costs at present high levels, and with a growing popular appreciation of the sphere of usefulness of heating apparatus in the home and in special locations in industry, there appears to be a potential market which can be uncovered by more energetic sales effort. Stocks are likely to be drawn down somewhat by sales of heaters for summer camps in this section, but the outlook for early purchases for warehousing purposes is not very bright. A good business is expected after the vacation season, but the present market is without feature.

## Variety of Demands for Magnet Wire Increasing Weekly

PRODUCERS of enameled wire report vigorous activity. The automotive industry is a large buyer and the radio manufacturer is also keenly interested in high-grade material of marked space economies. The variety of demands for magnet wire, both enameled and non-enameled, increases almost weekly, and in representative plants production has to be upon a practically continuous basis to satisfy current requirements. Raw-material costs are stiffening at this time, and prices are relatively unstable. The higher quality material tends to sell upon its merits, however, and builders of motor cars and other products who exercise discrimination in the selection of their material are contributing to the stabilization of the market when they purchase wire in mass or in coil form on the primary basis of quality. This has no direct appeal to some purchasing agents, apparently, but the preparation now given high-grade wire for use in automobile service and other important applications warrants thorough study of the material and more appreciation of processing requirements on the part of users.

## Farm Lighting Sets Are Expected to Move Faster

REPORTS of farm-lighting-set sales for the first quarter of 1923 indicate a much healthier trade than a year ago, and now that highway conditions in the rural districts of the north are improving, sales activity seems certain to increase still more within the next few weeks. It is not easy for the manufacturer or distribu-

tor in a city or large town to visualize some of the difficulties which accompany sales work in the field during the winter and early spring, under conditions where road travel is bad. In one Northern state last week a salesman started from a small town by motor to a sales district only 20 miles away, leaving at 8 a. m. He arrived at 8 p. m., after a day's battle with muddy roads and an outlay of some $20 for haulage. In the locality where this took place conditions will improve rapidly during the next fortnight, but the absence of convenient railroad service and sometimes the total lack of train facilities in such regions, coupled with highway difficulties, makes it costly and trying to sell this kind of equipment in areas far from central-station lines. It is done, none the less.

## Farm Sets Help Introduce Electric Service

REPORTS are coming in to the effect that in not a few communities the entrance of farm-lighting outfits is regarded with satisfaction by near-by central-station systems at present unable to reach these consumers except at excessive outlay. There appears to be a more cordial relationship between central-station sales departments and the farm-lighting-set representatives than was evident a while back. Some problems of difficult character remain in this relationship and in relation to the future customer and his equipment; but, on the whole, a leading distributor states, the outlook is gratifying and constructive in its possibilities. Local stocks of sets are, on the whole, well prepared for the spring and summer business. Prices are firm and may advance later, according to widespread ideas of the trend of costs. Year by year this class of equipment finds a growing market, and replacement business is a factor of increasing importance in the older sets, especially along the line of new battery plates. Optimism as to 1923 business was very generally manifested by those who attended one of the larger factory sales conferences in this line of equipment production a week or two ago.

## New England Collections Show General Improvement

IMPROVED credit conditions are still evident in New England, and increased discounting of bills is reported by jobbers. Railroad, public utility and large industrial-plant buying is on a more satisfactory basis than for a long time. Some contractor-dealer accounts are reported as slow, but underlying conditions are unusually good. Credit managers are working hard to keep conditions favorable as long as possible, and nothing like a "wide-open" policy can be discerned when expansion is proposed. Throughout this territory a tendency toward careful buying has unquestionably helped the credit situation. A few weeks ago collections were handicapped by severe weather and excessive delays in freight shipments, but these conditions are rapidly yielding to better transportation achievements and a rising tide of new business. While some contractor accounts run as high as ninety days, a fair average is about sixty. Much good work is being done by jobbers along the line of helping to stabilize retail business methods.

## Magnetic Clutch Sales Active with Advance Into Paper Field

VIGOROUS activity in the sale of magnetic clutches is reported in leading manufacturing circles, and the advance of this class of equipment into the paper-making field is a recent development that has been more or less overlooked. While a large part of the business in this line of products involves specialized engineering design and intelligent application analyses for lasting sales, the broader development of clutch production to include a wider contact with the requirements of the machine-tool industry is on the way, and a degree of standardization appears to be at hand. As in most other apparatus lines, prices are firm, labor none too plentiful in the factories, and deliveries not yet on a stable basis, although anticipation of raw material requirements and improving transportation conditions are working in favor of the buyer.

## Diversified Demand for Control Apparatus

WIDENING applications of control equipment are contributing to put manufacturers in this class of electrical products upon a plane of production taxing all their present facilities. The growth of motor sales and tendency toward the individual drive of machinery, coupled with severe requirements in speed variation, has thrown increased business upon controller builders. So far as motor control goes, the situation seems well in hand, however. The development of motor business from the dull period of a year or more ago to the present excellent volume has been very gradual, and it is highly creditable to control manufacturers that they are still able to make reasonably good deliveries on standard outfits, keeping well within the delivery promises of the motor builders. The marketing of modern control equipment is greatly influenced by the engineering requirements of great industries into which the variable-speed motor drive is making new records of efficiency. In the printing-press and paper-making fields, especially, the refinements of control demanded have opened new problems to the manufacturing engineer, and the solution of these on a shop rather than on a laboratory basis has resulted in a quickening of the market throughout these industries. Other developing industries are interactive with controller production. The steady advance of electric vehicle and industrial electric truck applications, the requirements of control in electric heating apparatus designed for chemical and physical laboratory service and the demands of a vacuum-tube set regulation by rheostatic control in radio work all spell increased orders for makers of control apparatus. One house alone has sold more than 500,000 small rheostats for radio service since last summer.

## Sales Service a Real Factor in Industrial Truck Situation

FIRM prices and a tendency toward longer deliveries mark the industrial truck situation, but as yet it is not difficult to meet reasonable requirements with satisfactory promptness. In this class of work 100 per cent service between the factory and the field representative has an immediate bearing upon the success of sales efforts. Delays in furnishing quotations and information to prospective buyers are injurious because of the detailed investigations which must precede contract awards in the great majority of cases. Poor mail service has hampered this business not a little in the past winter, but despite various handicaps sales have been made in increasing numbers and the outlook for a good year is excellent.

## Lamp Sales Reflect Growth of Industry

SUPERSEASONAL lamp sales are reported from manufacturers and distributors, and if production facilities had not been developed many months ago in far-sighted anticipation of the growing demand, a shortage could scarcely have been escaped during the past winter. The extension of electrical service grows like a rolling snowball in practically all parts of the country; replacement orders continue to mount higher each year, and the increased attention now paid to decorative lamp

## Comparative Prices of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | $0.0326 | $0.0322 | $0.0229 |
| Cold finished shafting, per lb. | 0.0406 | 0.0406 | 0.035 |
| Brass rods, per lb. | 0.1913 | 0.1870 | 0.1533 |
| Solder (half and half), per lb. | 0.30 | 0.2833 | 0.20 |
| Cotton waste, per lb. | 0.1231 | 0.1181 | 0.104 |
| Washers, cast iron (½-in.), per 100 lb. | 4.66 | 4.33 | 3.83 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 2.96 | 3.11 |
| Machine oil, per gal. | 0.349 | 0.349 | 0.40 |
| Belting, leather, medium, on list | 42% | 49% | 48½% |
| Machine bolts, up to 1-in. x 30-in., off list | 44¼% | 51¼% | 64¼% |

design and the enormous expansion of utility lamp applications in commerce, industry and the home, in the automobile field and in science tends to swell the totals of recurrent sales. Lamp prices are firm, with few if any recent changes; raw materials are well in hand at the factories, and labor-saving machinery is constantly being more effectively adapted to production conditions. While it is true that the winter season brings the peak of consumption to its annual maximum in this branch of the electrical industry, the highly organized sales efforts of the lamp maker are so carefully planned and carried out through the year, with remarkably able advance gaging of demand, that requirements are met with little outward evidence of wear and tear upon producers and distributors.

### Atlanta Shows Tendency to Increase Cash Discounts

COLLECTIONS for the past thirty days show improvement over the prior month, with a tendency toward an increase in the number of cash discounts taken. Credit men, as a rule, are extending a more liberal line of credit than has been the case for some time past, but are more cautious than during the last period of good business. A number of the jobbers report an increasing amount of cash sales, with money easy in middle and south Georgia and Florida. There has been voiced in isolated instances the fear that easy money will cause firms to overreach, with a resultant reaction in the late fall. Volume of business is on the increase, as is illustrated by the debits to personal accounts for twenty-five southeastern cities for March, the increase amounting to $30,000,000 over February.

## The Metal Market

A dull week with lower prices is reported. Rarely does it happen that demand for all metals should be so poor at one time. As consumption continues excellent in almost all lines, it is to be inferred that metal buyers have heeded the warnings of a possible inflation and the lessons learned in 1920 and are reducing their stocks and orders for future supplies of raw materials to the lowest possible amount consistent with safety.

NEW YORK METAL MARKET PRICES

| | April 18, 1923 Cents per Pound | April 25, 1923 Cents per Pound |
|---|---|---|
| Copper, Electrolytic | 17.00–17.25 | 17.00 |
| Lead, Am. S. & R. price | 8.25 | 8.25 |
| Antimony | 8.75 | 8.37½ |
| Nickel, ingot | 28.00–30.00 | 28.00 to 30.00 |
| Zinc, spot | 7.37½ | 7.37½ |
| Tin, Straits | 47.50 | 46.62½ |
| Aluminum, 98 to 99 per cent | 26.00–27.00 | 26.00 |

**Electrical Slate Sales in 1922.**—Sales of electrical slate in the United States during 1922 amounted to $976,022, according to the Geological Survey in a report just made to the Department of the Interior. Quantity sold amounted to 1,329,500 sq.ft.

# Activities of the Trade

Devoted to News of the Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

### Copeland Products, Inc., Will Make Refrigerating Units

Copeland Products, Inc., has been organized as a Delaware corporation for manufacturing electric household refrigerating units, with factories in Flint, Mich. Capitalization consists of 200,000 shares of no-par-value stock, 100,000 shares of which have been subscribed by Flint and Detroit people. Development work in connection with production has been in progress for a year, the work having been done by the Electricold Corporation, which the new company succeeds. Work will commence during the summer on a new building, but for the time being temporary facilities are being used. E. J. Copeland is president of the company.

### Westinghouse Electric Entertains McGraw-Hill Editors

Realizing the better service to their industries that technical editors can render by closer knowledge of manufacturers' problems and accomplishments, the Westinghouse Electric & Manufacturing Company entertained a group of McGraw-Hill editors at its East Pittsburgh works this week. The trip was specially arranged to see the company's engineers who were handling the work in which the editors were most interested. Special shop visits were also arranged so that they could see special equipment in course of construction. A luncheon and a dinner afforded still further opportunity for the editors and the company engineers to get acquainted and discuss problems of mutual interest.

### Cook Electric Will Manufacture in Chicago

The Cook Electric Company, 900 West Van Buren Street, Chicago, has sold its Zion plant to Wilbur Glenn Voliva and will move about May 1 to its recently purchased new plant at 2700 Southport Avenue, Chicago. This new building cost $150,000 and will contain the general offices and factory of the company. The floor area is 40,000 sq.ft., being equivalent to its floor capacity at Zion City. There is also about 32,000 additional square feet of vacant land.

President G. R. Folds stated that this change was made in order to obtain better unity of action since there has been considerable lost motion in manufacturing at Zion City and assembling in Chicago. The new arrangement, however, will afford better manufacturing facilities in the production of telephones and telephone equipment. About 1,000 sq.ft. of floor area will be added at the present time in the form of a tool vault. No change in the management occurred and the officers still remain: G. R. Folds, president; A. D. Edwards, vice-president; E. R. King, secretary-treasurer.

### Consolidated Supply Firms Move to New Quarters

The Fobes Supply Company, 523 Mission Street, San Francisco, wholesale electrical supplies, on May 1, will be consolidated with the Electric Railway & Manufacturers' Supply Company under the firm name of the Fobes Supply Company. On the same date the new company will move to its new building at 260 Fifth Street. Officials of the firm will be: F. N. Averill, president; R. J. Holtermann, general manager; B. S. Manuel, sales manager; R. F. McDonald, assistant sales manager, and E. J. Duggan, purchasing agent.

### Electric Machinery Firm Moves

The Electric Machinery Manufacturing Company, Minneapolis, has changed its Chicago office from the Fisher Building to 1141 Monadnock Building, 53 West Jackson Boulevard. This office will now be in charge of Will H. Peterson, district manager, with Howard B. Johnson as assistant district manager.

### Allis Chalmers 1922 Profits Amounted to $2,208,549

The net profits of the Allis Chalmers Manufacturing Company, Milwaukee, for 1922 were slightly lower than that of the year before, while the unfilled orders on hand at the close of 1922 were in excess of those of 1921, as shown in the annual report of the company just made public.

The net profit of the company for 1922 was $2,208,550, while in 1921 the net profit was reported as $2,215,468. Unfilled orders on hand at the close of the year amounted to $8,215,545 as compared with $7,300,574 in 1921.

In his report to the stockholders, President Otto H. Falk said that while the amount of unfilled orders on hand on Dec. 31, 1922, was not largely in excess of the year before, the prospect for 1923 is favorable and the orders for the present year will show a "substantial increase over the preceding year."

Inventories were priced at cost or market, whichever was lower. This resulted in a write-off of $333,903. The total value of all inventories on Dec. 31, 1922, was $10,009,030 as against

$12,504,188 the year before. During the year the holders of preferred stock increased from 3,295 to 3,591 and holders of common stock decreased from 3,833 to 3,715.

## Hubbard & Company Sales Appointment

Warren M. Heim, who has been district manager of Hubbard & Company, Pittsburgh, with headquarters at 30 Church Street, New York City, for the past two years, has recently been made assistant manager of the electrical materials department of this company in charge of sales, service and production.

Mr. Heim has been associated with the industry since 1910, when, after his graduation from the Pennsylvania State University, he joined the Long Island Lighting Company as construction engineer.

## Cutler-Hammer Arranges Texas and Oklahoma Agency

The Cutler-Hammer Manufacturing Company, Milwaukee, has made an agency arrangement with O. T. Jenkins, 1002 Pacific Avenue, Dallas, Tex., effective March 1, 1923, covering the sale of wiring devices, radio apparatus and standard industrial heating apparatus, such as soldering irons, space heaters, confectioners' appliances, water heaters, etc. The territory covered is Texas and Oklahoma.

## General Electric Completes Oakland Factory

To meet the increasing demands for electrical equipment in the West the General Electric Company has just completed and is now occupying its new $250,000 factory in Oakland, Cal. The building is of steel and brick construction and contains 45,000 sq.ft. of floor space. The factory will be used as an assembling plant and for the manufacture of transformers, switchboards and other equipment and will contain a service shop as well.

The lighting of the building received special consideration and is attracting attention because of the high intensity of illumination and the even distribution of light in all parts of the building.

An interesting feature of the operations that will be conducted in the plant is the instrument laboratory, in which will be maintained many electrical standards secured from Washington. About 150 men will be employed when the plant is in normal operation.

**The Inland Glass Company**, Chicago, incorporated for $750,000, to manufacture illuminating glassware, has begun operation on its new $500,000 plant. The project was promoted by J. B. Weaver, formerly vice-president of the Pullman Company, who is president of the new company, and H. Pickett Whithers, formerly of Marshall Field, Glore, Ward & Company, who is secretary-treasurer of the new company.

**The Gardner Electric Manufacturing Company**, Emeryville, Cal., recently incorporated with a capital stock of $50,000, has completed the erection of its building and the installation of machinery and is now on an operating basis. W. C. Gardner heads the company.

**The Kent Oil Burner Corporation**, 111 Broadway, New York City, has been organized to manufacture oil-burning equipment. Arrangements will be made to have the company's products manufactured by an outside plant, the corporation simply engaging in marketing and selling. This arrangement, however, is only temporary, and later the company expects to build a plant of its own. T. F. Kemp is president of the company.

**The Blaw-Knox Company**, Pittsburgh, manufacturer of steel transmission towers, reports the largest amount of unfilled business on its books in the history of the company. The company has declared the regular quarterly dividend of 1¾ per cent on the preferred stock and 2 per cent on the common stock, both payable May 1, to stockholders of record of April 20.

**The Foxboro Company**, Foxboro, Mass., manufacturer of electrical recording instruments, plans the erection of a four-story addition, 60 ft. x 160 ft.

**The Pacific Electric Manufacturing Company**, San Francisco, has leased additional floor space of approximately 15,000 sq.ft. in a building adjoining its present quarters. The new space will enable it to increase its manufacturing facilities so as to take care of the large volume of new business which the company is receiving.

**The National Carbon Company, Inc.**, is removing its "Ever-Ready" plant from Long Island City, New York, to Cleveland, where, it is stated, the company's production of flashlights and radio batteries will be quadrupled. The battery department will occupy a three-story building, erected during the war, which has been equipped for the new department. Among the executives who will be transferred from the Long Island plant will be A. V. Wilker, general superintendent; Charles Randall and W. H. Hines, in charge of production.

**The Walker Vehicle Company**, State and Eighty-seventh Streets, Chicago, manufacturer of commercial automobiles, has tentative plans for a new branch plant at New Orleans, to be used for electric trucks.

**The Peterson Storage Battery Company**, 323 South Lafayette Street, South Bend, Ind., is planning the erection of a new one-story factory, to cost approximately $30,000.

**The Electric Power Equipment Corporation** has just completed its new plant at 412 North Eighteenth Street, Philadelphia, where 30,000 sq.ft. of floor space will be used for manufacturing purposes. The former address of the company was at Thirteenth and Wood Streets.

**The Mercury Manufacturing Company**, manufacturer of storage battery trucks, 4118 South Halsted Street, Chicago, has let contracts for a one-story addition to its plant, to cost $40,000.

**The Metal Ware Corporation**, Two Rivers, Wis., which has increased its capital from $300,000 to $350,000, is taking over the manufacture of the electrical appliance line of the Harvey Electric Company, Chicago. D. C. Hughes, production manager of the Harvey Company, has been transferred to Two Rivers to supervise the department, in which electric irons, toasters and other electric products will be manufactured. C. F. Kirst is president of the Two Rivers Company.

**The Armature Rewinding Company**, 3305 Washington Avenue, St. Louis, has awarded a contract for a two-story plant, 50 ft. x 125 ft., at 605 North Leonard Avenue, for the manufacture and repair of electrical machinery, estimated to cost $50,000.

**The Quality Electric Company**, Los Angeles, manufacturer of electrical products, has plans for a new one-story factory, 40 ft. x 175 ft., at 812 San Pedro Street.

**The Marko Storage Battery Company**, 102 Jefferson Avenue, Brooklyn, N. Y., will soon take bids for the erection of a new two-story addition, 70 ft. x 90 ft., for considerable increase in capacity. It will cost approximately $50,000.

**Landers, Frary & Clark, Inc.**, New Britain, Conn., manufacturers of electric heating and cooking appliances, have completed plans for the erection of a three-story addition to their plant, to cost approximately $70,000. The company purposes to remove its present plant at Newark, N. J., to the main factory.

**The Connecticut Telephone & Electric Company**, Britannia Company, Britannia Street, Meriden, Conn., has completed plans and will take bids at once for the erection of a large addition to its plant.

**The H. T. Electric Service Company**, Indianapolis, has plans under way for the erection of a new two-story plant, 55 ft. x 195 ft., on North Capitol Avenue, estimated to cost $30,000.

**The Esterline-Angus Company**, 227 East South Street, Indianapolis, manufacturer of electrical equipment, is planning for the erection of a two-story plant at Blackford and New York Streets, to cost about $70,000. The present factory will be removed to the new location as soon as the structure is ready.

**The William A. Baehr Organization** has changed its Chicago office from the People's Gas Building to the Illinois Merchants Bank Building, 230 South Clark Street.

**The Louis Allis Company**, Milwaukee, manufacturer of motors, announces the establishment of its Alabama agency, the Commercial Electric Sales Company, 1322 Empire Building, Birmingham.

## Foreign Trade Notes

THE YATAWA (JAPAN) IRON WORKS TO BE EQUIPPED FOR ELECTRICAL OPERATION.—Definite plans are now being prepared, *Commerce Reports* states, for the general electrification of the Yatawa Iron Works of the Japanese government, which will involve an expenditure of 18,000,000 yen ($9,000,000) and cover a period of three years. The work will include the installation of electric cranes, conveyors, motors, etc.

ELECTRIC RANGES IN SOUTH AFRICA.—The Town Council of Durban, South Africa, according to *Commerce Reports*, is looking into a scheme for renting electric ranges to consumers of electricity. Electric heating devices are already freely used.

EXTENSION TO ELECTRIC PLANT IN YUNNANFU, CHINA, PROPOSED.—Plans are under consideration for extensions to the electric power plant in Yunnanfu, China, *Commerce Reports* states, which will include the installation of two 420-hp. water turbines, two generators, one of 350 kva. and one of 400 kva. capacity; switchboard equipment and accessories.

HYDRO-ELECTRIC SCHEME FOR CHINA.—The Foochow Electricity Company is planning to build a hydro-electric plant at the waterfalls between Shipping and Lungting, in the Kutien district, China.

NEW COMPANY FORMED TO SUPPLY ELECTRICITY IN MINAS GERAES, BRAZIL.—A company is being organized with a capital stock of 400,000 milreis (one milreis = $0.5462 at normal exchange), according to *Commerce Reports*, to supply electricity for lighting and power purposes in two cities in the State of Minas Geraes.

ELECTRICITY FOR ILOILO, PHILIPPINE ISLANDS.—Electricity for the city of Iloilo, Philippine Islands, *Commerce Reports* states, is to be provided by a new plant which is being installed by the Philippines Engineering Company. Plans are also being prepared for establishing an electric railway system, to cost about $500,000.

THE SUTLEJ VALLEY (INDIA) HYDRO-ELECTRIC PROJECT ABANDONED.—The Punjab Electricity Board is understood to have abandoned the Sutlej Valley hydro-electric project. The government proposes to concentrate on the Uhl River scheme in the Mandi State.

PROPOSED ELECTRIC PLANT FOR DURBAN, SOUTH AFRICA.—Application has been made to the Union government by the Town Council of Durban for permission to build a power station at Congella, under the new electricity act. A conference has been suggested by the government between the representatives of the Durban municipality, the Electricity Supply Commissioners (a body to be appointed) and the South African Railway Administration.

PROPOSED HYDRO-ELECTRIC DEVELOPMENT IN NEWFOUNDLAND.—A scheme has been approved by the advisory committee under the trade facilities act which aims to develop hydro-electricity to operate pulp and paper mills. It is proposed to utilize the water power of Deer Lake, from which it is estimated that between 230,000 hp. and 240,000 hp. could be developed. The plans provide for an initial plant of 100,000 hp. It is proposed to use electric boilers on a large scale for producing steam necessary for the production of pulp and paper. A sum of £4,000,000 will be guaranteed jointly by the British and Newfoundland governments. The hydraulic work will be in charge of W. G. Armstrong, Whitworth & Company, Ltd., who are interested in the project.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

An agency is desired in Turin, Italy (No. 6,127), for electrical novelties, etc.

An agency is desired in Paris, France (No. 6,137), for telephone and telegraph apparatus, including wireless.

An agency is desired in London, England (No. 6,146), for small motors, vacuum cleaners, washing machines, electric heating appliances, electric refrigerators, electric table fountains and similar specialties.

Purchase and agency are desired in Shanghai, China (No. 6,147), for rubber jars for storage batteries, 6-volt and 12-volt, etc.

An agency is desired in London, Canada (No. 6,148), for electrical specialties, lighting fixtures and wiring supplies.

An agency is desired in Melbourne, Australia (No. 6,168), for electrical supplies, automobile accessories and specialties and tools of these trades.

Purchase is desired in England (No. 6,171) for plumbing, heating and lighting equipment, etc.

An exclusive agency is desired in Johannesburg, South Africa (No. 6,149), for supplies for engineering and mechanical and kindred industries, such as electric lamps, grinders and machine tools.

## New Apparatus and Publications

DRY BATTERIES.—The National Carbon Company, Inc., Thompson Avenue and Orton Street, Long Island City, has added two new types to its steel case Columbia "Hot Shot" line of batteries.

FUSES.—Bulletin No. 200 issued by Schweitzer & Conrad, Inc., 4,435 Ravenswood Avenue, Chicago, covers the "S & C" extra high-potential fuse and other types of the "S & C" high-voltage fuses.

ELECTRIC DRILLS AND REAMERS.—The Hisey-Wolf Machine Company, Cincinnati, has issued bulletin No. 106, covering its "Hisey" portable electric drills and reamers.

INDUCTION VOLTAGE REGULATORS.—The General Electric Company, Schenectady, N. Y., has issued thirty-two leaflets giving construction details of its induction voltage regulators.

MOTOR.—Bulletin No. 132 issued by the Wagner Electric Corporation, St. Louis, describes and illustrates its "Pow-R-ful" motor.

BLUEPRINTING MACHINE.—The C. F. Pease Company, 813 North Franklin Street, Chicago, has developed the "Pease" sheet drier, which is designed for drying blue prints, negative prints and photographic prints.

WATER-TUBE BOILERS.—Bulletin No. 2 issued by the A. D. Granger Company, New York City, describes and illustrates the "Oswego" internally fired water-tube boiler.

ATTACHMENT FOR CONTROL SWITCHES.—A full automatic attachment that can be added to any type "CS" circuit-breaker control switch has been placed on the market by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pennsylvania.

FUSE BOX.—The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., is distributing leaflet No. 20,005, covering its type "OD" safety-first fuse box for use on circuits up to 100 amp. and 7,500 volts.

METERS.—The American Electrical Instrument Corporation, 147 Palisade Avenue, Union Hill, N. J., is distributing bulletins Nos. L-104, L-105 and L-107, entitled "'Aimco' Sliding Contact Tube Rheostat," "'Aimco' Vibrating Reed Tachometers" and "'Aimco' Vibrating Reed Frequency Meters" respectively.

PROTECTIVE RELAYS.—Bulletin No. 417-2 issued by the Condit Electrical Manufacturing Company, South Boston, Mass., covers its protective relays and accessories for electrically operating switchgear.

## New Incorporations

THE PUBLIC SERVICE ELECTRIC POWER CORPORATION OF NEW JERSEY, Newark, N. J., has been chartered to construct an electric superpower station on the Kearney Meadows. The officers are: Richard E. Danforth, president; Henry D. Whitcomb, vice-president; William H. Feller, secretary, and Frederick A. Neils, treasurer.

THE THORSBY (ALA.) LIGHT & DEVELOPMENT COMPANY has been chartered with a capital stock of $10,000 by A. E. Reagan, C. E. Lucas and Felix Elland.

THE MANN-FINK ELECTRIC COMPANY, Tacoma Park, D. C., has been incorporated by Leroy S. Mann, G. Ernest Fink and others. The company is capitalized at $10,000.

# Construction News

**Projects, Plans, Bids and Contracts; Contemplated or Under Way**

## New England States

AUGUSTA, ME.—The Maine Central Power Company has issued $600,000 in bonds, part of the proceeds to be used for extensions and improvements in its system.

RUMFORD, ME.—The Oxford Paper Company will install electric power equipment in connection with extensions, to cost about $300,000.

GORHAM, N. H.—The Twin State Gas & Electric Company, 160 State Street, Boston, has completed plans for a hydro-electric power plant to cost $275,000, for which a site has been acquired. R. J. Andrus is engineer.

LUNENBERG, VT.—The electric plant and system of the Lunenberg Manufacturing Company, which furnishes local commercial service, has been acquired by the Twin State Gas & Electric Company, 160 State Street, Boston. A transmission line will be erected to Lunenberg and extensions and improvements will be made to the local system.

LEE, MASS.—Plans, it is reported, are under consideration by the Smith Paper Company for the construction of an electric plant on the Housatonic River, between its Niagara and Centennial Mills.

WEYMOUTH, MASS.—The Edison Electric Illuminating Company, Boston, has awarded a general contract to Stone & Webster, Inc., 147 Milk Street, Boston, for the construction of the first unit of a steam-operated power plant, to cost about $5,000,000, with equipment.

NEW HAVEN, CONN.—The United Illuminating Company will build a transformer station at 34 Wallace Street.

## Middle Atlantic States

BUFFALO, N. Y.—Bids will be received by the Board of Education, Telephone Building, until May 2 for transformers, switches and other electrical apparatus for the vocational school on Elmwood Avenue.

NEW YORK, N. Y.—Bids will be received by the New York Central Railroad Company until May 4 for one 2,000-kw. rotary converter and one 2,100-kva. transformer, with switchboard and auxiliary apparatus. (Serial contract No. 13, 1923.) C. S. White, Room 344, 466 Lexington Avenue, is purchasing agent.

NEW YORK, N. Y.—Electric power equipment for general service, ice-manufacturing and refrigerating departments will be installed in the market building to be erected by the Department of Public Markets, Room 2337, Municipal Building, at Cromwell Avenue and the Harlem River, to cost about $6,000,000.

NEW YORK, N. Y.—Electric power equipment will be installed in the baking plant to be built by Cushman's Sons, Inc., 461 West 125th Street, on Lawrence Street, to cost about $150,000. L. S. Beardsley, 116 West Thirty-ninth Street, is architect.

SYRACUSE, N. Y.—The Syracuse Lighting Company contemplates extensions and improvements to its system during the next eighteen months, to cost about $4,000,000.

UTICA, N. Y.—The Utica Gas & Electric Company will erect a 110,000-volt transmission line to connect with the system of the Northern New York Utilities, Inc., Watertown, from which it will purchase hydro-electric power up to 25,000 kw., the service to begin in June. F. M. Tait is president and general manager.

FRANKLINVILLE, N. J.—Theodore Blank, Porchtown, plans to build a hydro-electric plant on lake property at Porchtown and Malaga. A transmission system will be erected to furnish commercial service at Franklinville and vicinity.

ALLENTOWN, PA.—The Amerag Corporation plans to build a power house in connection with its proposed plant at Greenawalds, a suburb, to cost about $500,000.

BROOKVILLE, PA.—The Jefferson Electric Company has been granted permission to acquire eight electric power companies

operating in this section and will merge the systems. Plans are under way for extensions and improvements.

EDGELY, PA.—The Margargee Paper Company, Modena, is preparing plans for a 4,000 kw. steam-operated electric generating plant in connection with its proposed new local mills. The cost of the project is estimated at $600,000.

HANOVER, PA.—The Metropolitan Edison Company, Reading, has acquired the properties of the Hanover Power Company and the Gettysburg (Pa.) Electric Company. The systems will be consolidated and extensions made.

HAWLEY, PA.—The Pennsylvania Power & Light Company, Allentown, plans to build a large local generating plant to furnish service to a number of distributing companies, now being organized as subsidiaries, to operate in parts of Carbon, Luzerne, Wayne, Lackawanna, Munroe and Pike Counties.

PHILADELPHIA, PA. — The Philadelphia & Reading Railroad Company, Reading Terminal, will build a power house at its proposed grain elevator (to cost about $3,000,000) in the Port Richmond section.

WILLIAMSPORT, PA. — The Keystone Glue Company is preparing plans for a power plant at its factory, to cost $200,000, including machinery.

ELKTON, MD.—The Northern Maryland Electric Company, Baltimore, plans extensions in its hydro-electric plant, in the vicinity of McCall's Ferry, on the Susquehanna River, increasing the capacity to 410,000 hp. The cost is estimated at $1,000,000.

LAUREL, MD. — The Annapolis Public Utilities Company has acquired the local municipal electric plant and will make extensions and improvements, including a transmission line.

MASON CITY, W. VA.—The Hutchison Coal Company contemplates rebuilding its power house, recently damaged by fire, causing a loss of about $40,000.

NORFOLK, VA. — The Norfolk Sugar Refining Company, recently organized, plans to build a power house in connection with a local sugar refinery, to cost about $750,000. J. B. Morgan and J. H. Caldwell, both of Norfolk, are interested in the company.

WASHINGTON, D. C.—Bids will be received by the Chief Signal Officer, United States Army, until May 3, for 2,093 connecting switchboard cords (Proposal 13488-A-2ACP).

## North Central States

TOLEDO, OHIO.—The Ajax Rubber Company, Trenton, N. J., plans to build a substation at its proposed local tire-manufacturing plant. The cost of the work is estimated at $200,000.

TOLEDO, OHIO. — The Toledo Edison Company is installing an additional 30,000-kw. turbo-generator unit at its Acme station. J. F. O'Connor is manager of the electric department.

TOLEDO, OHIO. — The Toledo Edison Company has issued $1,500,000 in capital stock, part of the proceeds to be used for extensions and improvements.

PINEVILLE, KY.—The Kentucky Utilities Company plans to erect a local power plant, to cost about $100,000, for which a site has been acquired.

CHANDLER, IND.—The Boonville (Ind.) Electric Light & Power Company is erecting a transmission line to Chandler (6 miles long) to supply electricity here and to the farmers and the coal mines along the route. K. H. Weyerbacher is manager.

INDIANAPOLIS, IND.—Plans are under way for equipping the plant of the Lavelle Foundry Company, Michigan Street, for electrical operation throughout.

LAFAYETTE, IND.—A power plant will be built at the Indiana State Soldiers' Home, for which bids will be called at once. W. M. Louden is commandant.

MARION, IND.—The Upland Flint Glass Company will install electric power equipment in connection with the rebuilding of its local plant, recently damaged by fire, causing a loss of about $100,000.

BAYFIELD, WIS.—Plans are under consideration to purchase electricity to operate the municipal system from a hydro-electric plant under construction at Port Wing, Orienta Falls, and to extend the lines to La Pointe and Madelaine Island, a distance of 3 miles, by a submarine cable. L. W. Barnes, is superintendent.

BELLEVILLE, WIS. — The Belleville Electric Light & Power Company contemplates extensions to its light and power lines, to cost about $10,000.

JOHNSON CREEK, WIS.—The installation of a new ornamental lighting system is under consideration. It is proposed to replace the three-lamp clusters with single-lamp posts.

OCONTO FALLS, WIS.—The Falls Manufacturing Company contemplates the construction of a power house in connection with a new paper mill, to cost about $160,000.

OSHKOSH, WIS.—The Wisconsin Public Service Corporation is planning to erect a 6,600-volt transmission line from Oshkosh to Pickett, which will also supply electricity to Fisk and Elo.

ST. CLOUD, MINN.—Expansion of the terminals of the Great Northern Railway Company at St. Cloud, to cost about $500,000, include a power house, roundhouse, machine shop, etc.

BROOKFIELD, MO.—At an election to be held April 30 the proposal to issue $95,000 in bonds to construct a municipal electric light plant will be submitted to the voters.

ST. JOSEPH, MO.—Plans for a proposed local cement-manufacturing plant to be erected by Claude H. Light, Garden Grove, Iowa, and associates, to cost about $250,000, include a power plant.

MERRIMAN, NEB. — Plans are under way to extend the electric transmission lines of the Cornell Hydro-Electric Company at Valentine to Gordon and Merriman.

WICHITA, KAN. — The Kansas Milling Company has authorized plans for a one-story power plant in connection with a new mill. The Benham Engineering Company, Gumbel Building, Kansas City, Mo., is consulting engineer.

## Southern States

ANDREWS, N. C.—Bonds to the amount of $350,000 have been authorized by the Board of Aldermen for the construction of a hydro-electric plant on the Hiawassee River, to develop about 1,500 hp. The Ludlow Engineers, Inc., Engineers, Winston-Salem, will have charge of the work.

AINSLIE, GA.—The Southeastern Portland Cement Company, Macon, recently organized, plans to erect a power house at its proposed local cement-manufacturing plant, to cost about $500,000. W. Jordon Massee is president.

AMERICUS, GA. — The South Georgia Public Service Company has purchased the system of the Americus Lighting Company. A transmission line will be erected from Albany, Ga.

DAYTONA, FLA.—The Daytona Public Service Company plans to install additional equipment in its plant.

GARY, FLA.—The Tampa Glass & Bottle Manufacturing Company, Tampa, plans to build a power house at its proposed new local plant.

MIAMI BEACH, FLA. — An improved street-lighting system will be installed to cost about $20,000, for which bonds have been voted.

BELLS, TENN.—The Bells Light & Water Company contemplates installing an ice plant in connection with its electric plant. A. T. Chronister is manager.

KNOXVILLE, TENN.—The Knoxville P. & M. Mortar Company plans to build a power house in connection with its proposed local works for cement plaster, fireclay, etc. W. B. Townsend is the president of the company.

BIRMINGHAM, ALA. — The Alabama Power Company contemplates building an additional hydro-electric power plant on the Warrior River, to cost about $1,000,000.

MONTGOMERY, ALA. — The Alabama Power Company has issued $4,000,000 in bonds, part of the proceeds to be used to acquire the properties of the Montgomery Light & Water Power Company, Montgomery Light & Traction Company, Power Transmission Company and the People's Electric Light & Ice Company, and for proposed extensions and improvements to the systems.

CANTON, MISS.—Bonds have been voted for extensions and improvements in the municipal lighting system and waterworks, to cost about $75,000.

POPLARVILLE, MISS. — The Southern Power & Manufacturing Company, New Orleans, plans extensions to the local electric plant, lately acquired. It is also proposed to install an ice-manufacturing and refrigerating plant.

GIBSLAND, LA.—A bond issue of $50,000 has been authorized for the installation of an electric system and improvements to waterworks.

SHREVEPORT, LA. — The Red River Refining Company plans to build a power house in connection with a new local oil-refining plant, to cost about $500,000.

ENID, OKLA.—Plans for the proposed terminal grain elevator, to be erected by the Enid Terminal Elevator Association, at a cost of about $500,000, include a power house.

MULDROW, OKLA.—The municipal electric plant has been acquired by the Oklahoma Gas & Electric Company, which will furnish service from a new transmission line. The local plant will be remodeled for a substation.

EDGEWOOD, TEX.—Bonds to the amount of $15,000 have been voted to establish a municipal electric light plant.

GRANBURY, TEX.—Bonds to the amount of $28,000 have been voted for the installation of an electric light and power system.

HULL, TEX.—The Gulf Production Company will build an electric power plant, with transmission lines for power service, at its oil properties, to cost about $1,000,000.

## Pacific and Mountain States

GRANITE FALLS, WASH.—The Puget Sound Light & Power Company, Seattle, plans to extend its transmission line from Granite Falls to Hartford.

MARBLE, WASH.—The Stevens County Power & Light Company will build a transmission line from Colville, through Echo Valley and Lake City, to Marble.

SEATTLE, WASH.—The City Lighting Department is considering plans for the installation of new lighting units on streets in the main business district.

TACOMA, WASH.—The Tacoma Harbor Lumber Company, recently organized, will build a power house at its proposed local mill. The cost of the project is estimated at $100,000.

VANCOUVER, WASH. — Contract has been awarded by the Columbia River Paper Mills Corporation to the Gilpin Construction Company, Portland, Ore., for the first unit of its proposed work,s to cost about $200,000. A power plant and machine shop will be built later. The entire plant, including other units, will cost about $1,200,000.

CORNING, CAL.—A hydro-electric development by utilizing water power secured from Trinity River in Trinity County is under consideration by W. H. Samson, Corning, and associates. The plans call for a development of 285,000 hp. and the use of the water later for irrigating 400,000 acres of land in Glenn, Colusa, Yolo and Tehama Counties. Two hydro-electric plants are planned, to cost about $30,000,000.

LONG BEACH, CAL. — Bonds to the amount of $80,000 have been voted for the installation of an electric fire-alarm system.

LOS ANGELES, CAL.—Bids will be received by the County Board of Supervisors until May 7 for furnishing and installing one steam-turbine-driven electric generator at the County Hospital.

LOS ANGELES, CAL.—Electric power equipment will be installed in the two-story ice-manufacturing and cold-storage plant to be erected by the Los Angeles Ice & Cold Storage Company on Mesquit Street, to cost about $50,000. John E. Kunst, 820 Higgins Building, is architect.

OAKLAND, CAL. — Bids will soon be called for the installation of an ornamental lighting system in the Lake Merritt district. Howard Gilkey is engineer.

ROSEVILLE, CAL.—Plans are under consideration for the installation of an ornamental lighting system on Church and Lincoln Streets.

SANTA ANA, CAL.—Plans are being prepared for the installation of an electric fire-alarm system, to cost $25,000, for which bonds have been voted.

WINKLEMAN, ARIZ. — The Arizona Portland Cement Company, Phoenix, will build a power house at its proposed cement-manufacturing plant. The cost of the project is estimated at $750,000.

## Canada

NELSON, B. C. — The Street Railway, Light and Power Departments contemplate extensions of transmission line (11 miles) to supply electricity for lighting and mines in the rural districts. G. T. McGuire is general superintendent.

ROSSLAND, B. C.—Plans to increase its hydro-electric developments at Bonnington

Falls on Kootenay River from 30,000 hp. to 60,000 hp. is under consideration by the West Kootenay Power & Light Company.

ST. JOHN, N. B.—The New Brunswick Electric Power Commission contemplates the erection of approximately 30 miles of additional low-tension rural feeder lines. G. A. Vandervoort is the general superintendent.

PARRY SOUND, ONT.—The Public Utilities Commission contemplates building two storage dams and also the installation of a 1,200-kva. generating unit and extensions to the distribution system. As yet nothing definite has been decided upon. W. F. Lockard is manager.

ESTEVAN, SASK.—The installation of a 300-kw. steam-engine-driven generator, three-phase, 60-cycle, 2,300 volts, and the erection of 1 mile of high-tension transmission line is under consideration by the Municipal Electric Light Department. J. B. Hamilton is manager.

MELVILLE, SASK. — The Light and Power Department is considering the installation of a lignite coal producers and tar-extracting machinery. James Anderson is superintendent.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued March 27, 1923)

1,450,156. Electrolytic Apparatus; J. N. Smith, Toronto, Ont., Canada. App. filed April 7, 1921. Electrolysis of saline solutions, production of oxygen and hydrogen or electrodeposition of metals.

(Issued April 3, 1923)

1,450,172. Swivel-Plug Connector; E. Dewald, Sr., Cincinnati, Ohio. App. filed March 8, 1920.

1,450,246. Piezo Electric Resonator; W. G. Cady, Middletown, Conn. App. filed Jan. 28, 1920.

1,450,253. Switching Device; H. A. Douglas, Bronson, Mich. App. filed Aug. 15, 1918. Switch for lamp socket such as is used on automobile instrument board.

1,450,254. Balancing Arrangement for Multiplex Carrier Circuits; L. Espenschied, Hollis, N. Y. App. filed Sept. 26, 1919. Balancing transmission circuit for several frequencies.

1,450,265. Hot-Cathode Tube; J. Slepian, Wilkinsburg, Pa. App. filed April 18, 1919. Used for rectification and in detector-bulb work.

1,450,275. Wireless Amplifier; C. T. Alcutt, Pittsburgh, Pa. App. filed Dec. 31, 1918. Cathode of a vacuum-tube amplifier, an electrode opposite cathode, a second electrode in plane parallel to cathode, and grid between the two electrodes.

1,450,276. Trolley Crossing; R. E. Andrew, Philadelphia, Pa. App. filed Feb. 21, 1922. Insures smooth passage of trolley wheel.

1,450,277. Waffle and Hot-Cake Iron; E. N. Brown and A. M. Lambert, San Francisco, Cal. App. filed Jan. 31, 1922. Reversible plates heated by variable-resistance elements.

1,450,294. Welding Tool; J. Jerry, Milwaukee, Wis. App. filed Dec. 29, 1920. For holding electrode or fusing strip.

1,450,305. Telephone Signaling System; W. A. Rhodes, New York, N. Y. App. filed Oct. 25, 1919. Means for providing "disconnect" and "busy" signals for telephone systems.

1,450,310. Lining for Conduit Outlet Boxes; W. M. Silliman, Syracuse, N. Y. App. filed Oct. 17, 1918. Lining or trim inserted which separates box into compartment.

1,450,321. Party-Line Revertive Ringing System; A. E. Lundell, Chicago, Ill. App. filed June 4, 1920. Full mechanical system of large capacity.

1,450,337. Automobile Signal; M. D. Shiverick, Albany, N. Y. App. filed March 14, 1921. Rear direction and stop signal.

1,450,339. Intermittingly Operating Motor System; R. S. Smith and J. L. Adams, Jr., Milwaukee, Wis. App. filed Oct. 20, 1919. Method of driving motor at varying speed in recurrent periods of rising and falling frequency.

1,450,347. Trolley and Feed-Wire Clamp; L. E. Armentrout, Borderland, W. Va. App. filed Jan. 3, 1923. Employed to suspend trolley and feed wires from mine roofs.

1,450,352. Selecting Switch for Use in Telephone Systems; K. Böhme, Berlin-Siemensstadt, Germany. App. filed Nov. 3, 1922. Decreased height of switch.

1,450,362. Electric Coil; P. Gilinson, Lowell, Mass. App. filed Feb. 10, 1919. Means for supporting and insulating various layers of windings of electric coils.

1,450,413. Vacuum Electric Dischagre Device; H. W. Edmundson and W. T. Munro, Rugby, England. App. filed March 10, 1919. Shield mounted in vacuum tube cuts off head radiated from anode.

1,450,415. Protective Device; H. G. French, Schenectady, N. Y. App. filed July 26, 1917. For protecting polyphase motors under unbalanced load conditions.

1,450,420. Sensitized Film Holder for X-Ray Photography; J. A. Heidbrink, Minneapolis, Minn. App. filed April 21, 1921. For dental work.

1,450,425. Protection of Alternating-Current Distributing Circuits; R. V. Bingay, Pittsburgh, Pa. App. filed Oct. 17, 1919. Protection of lines against high voltage of primary side of transformers.

1,450,439. Recording Phonograph; R. Hase, Berlin, Germany. App. filed Feb. 18, 1921. Speech recorded by aid of electromagnetic sound box.

1,450,464. Crystal Formation; E. Thomson, Swampscott, Mass. App. filed July 26, 1920. Alumina, beryllia, etc., made in electric furnace.

1,450,500. Flashlight; C. W. Harvey, New London, Conn. App. filed Jan. 17, 1922. Self-contained generator.

1,450,521. Armature for Dynamo-Electric Machines; A. Steinbach, Chicago, Ill. App. filed Dec. 31, 1921. Sectional armature core with coil on each section.

1,450,533. Storage Battery and Process of Producing the Same; A. H. Williams, Worcester, Mass. App. filed April 16, 1920. Relates to construction of plates.

1,450,543. Method and Device for the Heating of Material in Electric Furnaces; E. A. A. Grönwall, Stockholm, Sweden. App. filed Sept. 28, 1921. For the heattreating of metals.

1,450,563. Trouble-Locating Device; W. T. Powell, Rochester, N. Y. App. filed May 16, 1919. For locating apparatus trouble on telephone systems.

1,450,564. Telephone-Exchange System; F. M. Slough, Rochester, N. Y. App. filed Jan. 24, 1918. Exchange system in which calls are automatically extended by mechanical means to different idle call-receiving apparatus.

1,450,565. Secondary of Storage Battery; E. W. Smith, Philadelphia, Pa. App. filed Jan. 30, 1922. Plate consists of perforated tubes containing active material and metallic cores which act as conductors.

1,450,572. Reversing and Control Switch; O. Bahls, Long Island City, N. Y. App. filed Dec. 15, 1921. For electric vehicles.

1,450,589. Combined Heating and Cooling Device; G. Graff, New York, N. Y. App. filed Jan. 31, 1921. Ventilation system.

1,450,620. System for Regulating Frequency; H. E. Warren, Ashland, Mass. App. filed Dec. 13, 1918. Combined synchronous motor and clock indicates any change in frequency.

1,450,658. Oil-Well Heater; M. Warnick, Los Angeles, Cal. App. filed Dec. 6, 1921. Electric heater placed in bottom of well to facilitate pumping of oil.

1,450,668. Apparatus for Moving Furnace Electrodes; W. Dyrssen, New York, N. Y. App. filed Feb. 25, 1921. Automatically controls raising and lowering of electrodes.

1,450,725. Electrical Resistance Heating Element and Process of Making Same; F. Hodson, Philadelphia, Pa. App. filed May 22, 1922. Resistors of graphitic carbon.

1,450,749. Apparatus for and Method of Controlling Electric Currents; G. W. Pierce, Cambridge, Mass. App. filed March 11, 1914. Control of periodic current by another current or electromotive force the character of which it is desired to alter.

1,450,833. Steam-Heating Appliance; P. Bergeon, Grenoble, France. App. filed Oct. 6, 1921. Water vaporized by electrodes.

1,450,885. Trolley Construction; J. F. Healy, Chicago, Ill. App. filed May 25, 1921. Trolley pole operated by fluid-pressure cylinder.

1,450,898. Motor Controller; H. W. Cheney, Milwaukee, Wis. App. filed Dec. 6, 1919. Compensator for starting motors on low voltage.

1,450,902. Dynamo-Electric Machine; S. H. Mortensen, Milwaukee, Wis. App. filed Dec. 3, 1920. Flywheel for vertical waterwheel generators.

1,451,392. Electrode for Electric Arc Cutting or Reducing; C. J. Holslag, South Orange, N. J. App. filed Nov. 15, 1921. Electrode of rectangular cross-section.

1,451,426. Spark-Gap Apparatus; L. J. Lesh, New York, N. Y. App. filed April 9, 1918. Spark-gap apparatus of the multiple-unit gap type for use in radio transmitting and receiving sets.

1,451,427. Spark-Gap Apparatus; L. J. Lesh, New York, N. Y. App. filed June 5, 1918. Rotary gap for wirelss transmission.

1,451,465. Power-Transmission Apparatus; A. H. Neuland, San Francisco, Cal. App. filed May 13, 1916. Engine-generator-motor set for vehicles.

1,451,495. Audible Signal Device; J. L. Dinsmoor, Philadelphia, Pa. App. filed Aug. 7, 1917. Vibrating electric horns for automobiles.

1,451,500. Process and Means for Removing Corroded Terminals for Storage Batteries; G. E. Frohbeiter, Princeton, Ind. App. filed Sept. 11, 1922. By heating corrosion.

1,451,501. Speed-Regulating Apparatus; V. A. Fynn, St. Louis, Mo. App. filed July 5, 1919. Electromagnetic means for controlling supply of fuel to internal-combustion engines.

1,451,502. Speed-Regulating Apparatus; V. A. Fynn, St. Louis, Mo. App. filed July 5, 1919. Electromagnetic control for internal-combustion engines.

1,451,529. Resistor Element; Q. A. Brackett, Pittsburgh, Pa. App. filed Aug. 5, 1919. Grid leaks for vacuum-tube radio sets.

1,451,537. Electric Heater; M. D. Dominguez, New Orleans, La. App. filed May 1, 1922. Automatic water heater.

1,451,539. Electric Heating System for Ironing Machines; F. F. Forshee, Flint, Mich. App. filed Feb. 14, 1921. Method of maintaining constant temperature on heating surfaces.

1,451,543. Electroplating with Zinc; J. Haas, Jr., Muncie, Ind. App. filed Sept. 16, 1922. Electroplating of zinc or its alloys upon iron or steel in cyanide baths.

1,451,548. Contact Terminal; H. Kreisheld, Mansfield, Ohio. App. filed Nov. 20, 1919. Plug-and-socket contact for electrically heated apparatus.

1,451,550. Starting System for Automobiles; W. P. Loudon, Edgewood Park, Pa. App. filed April 14, 1920. Starting motor.

1,451,555. Arc-Welded Truss; W. Schenstrom, Brooklyn, N. Y. App. filed Oct. 11, 1920. Relates to framed-beam building construction.

1,451,556. Electric Percolator; F. Thornton, Jr., Wilkinsburg, Pa. App. filed June 29, 1922. Simple construction of vaporizing chamber.

1,451,558. Electropercussive Welding System; C. F. Wagner, Pittsburgh, Pa. App. filed May 14, 1921. Automatic control.

1,451,559. Section Insulator; N. A. Wahlberg, Wilkinsburg, Pa. App. filed June 3, 1921. For trolley wires.

1,451,577. Dynamo-Electric Machine; P. H. H. Jantzen, London, England. App. filed April 10, 1920. Means for cooling stator and rotor of dynamo-electric machines.

1,451,618. Flashlight; H. M. Koretzky, New York, N. Y. App. filed June 27, 1921. Accidental lighting prevented.

1,451,623. Soldering Iron; E. Millner, St. Louis, Mo. App. filed May 3, 1920. Electric heating element.

1,451,636. Electric Heater; R. Ullrich, Wels, Austria. App. filed Sept. 12, 1922. Cooking apparatus heated by electric energy, with automatic device for making and breaking circuit.

1,451,671. Electric Water Heater; W. G. Carter, Monrovia, and F. W. Thompson, Arcadia, Cal. App. filed Feb. 28, 1922. Tank heating system for hot-water-pipe lines.

Electrical World

*The consolidation of Electrical World, Electrical Engineer and American Electrician*

# Making Progress by Mingling Theory with Practice

THAT theory and practice can mix—and much to the advantage of the electrical industry—was strikingly shown at the spring convention of the American Institute of Electrical Engineers, held last week in Pittsburgh. Nearly twelve hundred electrical engineers were gathered there to take part in or listen to a program which contained both highly technical and highly practical papers, and the results showed conclusively that the practical or operating engineer and the technical specialist can meet jointly and discuss their problems and experiences to mutual advantage.

The story of the convention, with the details of its papers and discussions, is told elsewhere in these pages. It is enough to point out here that essentially the convention, in its technical aspects, was an exposition of some important operating problems of the light and power industry and that it was notable for the presentation of many papers filled with data obtained in the field. A judicious selection of theoretical and technical papers added vitality to the discussion, and there was thus formed a well-proportioned picture of the subjects under consideration. Agreement was expressed on the advantages of operating with a grounded-neutral system; the field for application of the neutral grounding reactor was defined, and a great deal of progress in relay design and application was shown. In addition, outstanding progress in illuminating engineering practice was evidenced, and a noteworthy revival of interest in the design and application of electric furnaces was evident.

BUT, while the details are of interest, most important is the fact that a general feeling of power to accomplish and of confidence and optimism concerning the future was quite evident. Many hitherto vexatious engineering problems have been solved. In fact, as M. H. Aylesworth observed in his banquet address, the status of electrical engineering has advanced so rapidly that the realization of an electrified America is delayed, not by lack of engineering knowledge and ability, but only by legal, economic, social and political handicaps. In other words, while there is real engineering work to do, yet from the viewpoint of engineering, superpower is an easy task.

Thus have the co-operative thinking and the personal contact of the electrical engineers made for progress. Engineers of groups from separate commercial divisions, with operating, manufacturing, or theoretical training and experience, meet together as unbiased professional men and discuss their problems in a friendly and constructive spirit. It is worth noting, too, that the younger engineers took an unusually prominent part in the meetings. More of the mingling of theory and practice would seem advisable to attain the maximum of progress in engineering work for the electrical industry.

# Otto Herbert Falk

*A manufacturing executive who adds to his commercial leadership by participating actively in public affairs*

AS CHIEF executive of the Allis-Chalmers Manufacturing Company since 1913 General Otto H. Falk has become an important factor in the electrical manufacturing field, where that company plays so prominent a part. Ten years ago the affairs of the company became involved, and the banking houses concerned turned to General Falk, who has large financial interests in Milwaukee, as a man eminently fitted to shoulder the responsibility of clearing up the situation. He became receiver of the company in 1912, and on its reorganization in 1913 he was made its president. It is to his ability in handling financial affairs that the Allis-Chalmers Manufacturing Company owes its present-day position as a producer of electrical, hydraulic and other machinery.

General Falk is a native of Wisconsin, having been born in Milwaukee in 1865. After receiving collegiate training in Northwestern College at Watertown, Wis., military tastes led him to become a pupil in the Allen Military Academy of Chicago, from which he was graduated as ranking captain in 1884. Ever since 1886 he has been an active factor in Wisconsin military affairs, stepping rapidly from grade to grade. In 1893 he was appointed adjutant general of the Wisconsin State militia. He was called into active service during the Spanish-American War, at which time he was commissioned as major and chief quartermaster. On his discharge he again became active in the Wisconsin National Guard, retiring with the rank of brigadier-general in 1911.

General Falk, in addition to his financial and military interests, is an important factor in Milwaukee's civic, social and business affairs. For a long time he was president of the Merchants & Manufacturers' Association of Milwaukee, serving on its legislative committee and becoming a member of the charter convention and chairman of the track elevation committee. He is a regent of Marquette University, and he has been fire and police commissioner of Milwaukee, vice-president of the public safety committee, and a delegate to national conferences on many important matters.

# Editorial Comment

Electrical World, May 5, 1923

Volume 81 Number 18

### Regulation Responsive to Public Opinion

A MOST interesting address was delivered by L. F. Loree, president of the Delaware & Hudson Company, at the centennial celebration of the chartering of that railroad. The vital part of the address comprised a peppery criticism of our system of regulation, which Mr. Loree stigmatizes as "repugnant to the genius of American political ideals and institutions." We do not so read history or interpret it. It may be that "railroading is no longer a business, it has become a calamity," but that view certainly does not hold for the electric light and power industry. Nor, indeed, would the railroads find it so if they took a more optimistic view of conditions and paid a little more attention to public relations. Every one recognizes that the railroads are vitally essential. No one seeks to destroy them or willingly wishes to cripple them. If they are maltreated, the fault rests with the railroads themselves. We have found regulation to be exceedingly responsive to public opinion, and that, properly enlightened, is constructive and not destructive. If the viewpoint of the railroads is otherwise, they should seek enlightenment and change their thought. Optimism and faith have been known to work miracles.

### Cost of Living and Price of Electricity

INDEX figures showing changes in the cost of living have been published for some years by the Labor Bureau in Washington and by special departments in various other countries of the world, as well as by private bureaus. The government's index figures are predicated on the normal household budget of the average workingman for food, clothing, housing, fuel, light, household goods, etc., compared with the cost of similar commodities in 1914, which year is used as a base. These serve a useful purpose and are employed principally in establishing wage scales. In the published tables and curves fuel and light are combined, and while the curve tells a true story, it does an injustice to the electric light and power industry, because, while the combination shows a large increase, the cost of electricity may have actually decreased. This, of course, is of no concern to the agitator or the yellow press, either or both of whom will, when it serves their purpose, quote the official figures as if they pertained to light only.

Fortunately, the Bureau of Labor Statistics is headed by a broad-gaged commissioner, Ethelbert Stewart. Mr. Stewart, when the matter was brought to his attention, recognized how unjust such a grouping was to a regulated industry. Accordingly he set about to right the wrong, and in the digest given to the daily press last week a note was added showing the percentage of increase or decrease in the price of electricity at specified dates compared with the price in December, 1914. The figures, which are based on simple averages of primary rates, show that while fuel and light cost 86.2 per cent more in March, 1923, than in December, 1914, electricity actually cost 2.4 per cent less. In fact, with the exception of the quarter ended December, 1920, which showed the slight increase of 1.2 per cent in the cost of electricity, all other quarterly periods since 1914 show a decrease ranging from 4.8 per cent to 1.2 per cent, the cost of fuel and light during that same period having increased from 24.1 per cent in December, 1917, to 86.2 per cent in March, 1923. The government's figures speak for themselves and the electrical industry takes commendable pride in them.

### Give Us the New Code—Now!

SOME very constructive changes have been made in the National Electrical Code, and a general revision in the phrasing and arrangement of the code is now in process. There is a question, however, as to how and when to put the new rules into effect. The authorized changes offer considerable advantage to the public in the wiring of private houses. Naturally, therefore, owners and contractors desire to apply them at once. Dana Pierce, chairman of the electrical committee of the National Board of Fire Underwriters, wrote a letter to the ELECTRICAL WORLD, which was published on April 14, to answer publicly the "numerous inquiries" he is receiving as to whether these changes were now operative. Mr. Pierce stated that the new code embodying the revision would be printed and made ready as soon as possible, but that he could not say when it would be issued. He gave it as his opinion, however, that it would be best if the 1920 code remained in effect until the 1923 edition is out.

R. S. Hale, in this issue, challenges the policy advocated by Mr. Pierce, asking whether the inspection department must wait upon the convenience of the printer without regard to the interests of the public. Should the inspector, he asks, "forbid certain forms of construction not because they are unsafe but merely because a certain book has not been printed"? It would seem that this point is well taken, and particularly in view of the fact, which Mr. Pierce himself stressed, that, anyway, each inspection department will "decide for itself" when it will begin to operate the new code after it is formally received.

Now, it so happens that the American people are at present engaged in the largest building program in history. About four billion dollars is to be spent, it is estimated, and of this at least 3 per cent, or $120,000,000, will be paid out for electrical construction. The important question is: Are the men and women who

will be investing their money in new buildings to have the benefits which the new changes in the code make possible to them or must it be withheld? The whole purpose of the code is, after all, to guide the owner, architect, contractor and insurance underwriter to safety in electrical construction, but the interests of the owner assuredly come first, by weight of numbers if for no other reason.

The issue should be decided, therefore, purely on the basis of safety. If the new accepted rules are safe, then in common justice they should apply to houses now building as well as to those other houses which will be building later on when the printer of the revised code book has finished his work. Meanwhile the principal revisions have been published in the ELECTRICAL WORLD (March 24) and other papers, so that they are not unknown to the inspectors and other concerns. Some additional means should be found to place the new rules in the hands of all inspectors immediately in temporary form pending the publication of the 1923 code, and they should be encouraged to apply them so that the American people may have the benefit of them now while they are most needed.

## Railroad Electrification Discussed on Higher Plane

RECENT discussions by electrical engineers on the subject of railroad electrification show that this question is at last being considered from the standpoint of those who operate the railroads. The most recent appearance of the subject was at the Pittsburgh A. I. E. E. convention last week, when a short discussion pointed directly to the fact that the transportation advantages and economies other than fuel economies were really the deciding factors.

A. H. Babcock's paper at the meeting was a worth-while contribution to the subject of relative fuel consumption by steam and electric locomotives, adding to the material presented a year or so ago at a joint meeting of the engineering societies. Although Dr. Cary T. Hutchinson questioned some of the conclusions from the results, yet the principal point finally made by W. J. Davis, and agreed to by R. S. Twogood, Mr. Babcock's representative, was that fuel economy would never be the determining factor, except as water power might enter as an element of conservation. The facts which will be considered by the railroad executives are those having to do with improvement of transportation, greater usage of tracks, reduced locomotive maintenance, reduced wages per train-mile and per ton-mile, reduced maintenance-of-way expenditures, etc., and greater dependability of continued safe and reliable service.

Not once was "A. C. versus D. C." mentioned. Engineers know that they can do the necessary engineering, make the necessary engineering decisions on any individual electrification problem. They are realizing that what really counts is the fact that electrification pays. There will doubtless be further discussion by engineers on the technical features of electrification —it would be too bad if there were none. But, whether or not present developments will lead to a common system, as they may, the future discussions of electrification should be, and doubtless will be, on a plane to promote it on its logical basis—improvement of transportation.

## Twelve Hundred Pounds Steam Pressure for Boston

THE expected use of steam pressures approximating 1,200 pounds per square inch in one of the boilers and in one small turbine in the new Weymouth station of the Boston Edison company marks another daring advance in engineering and serves again to focus attention upon the problems of boiler, turbine and fittings design which must be solved in order to reap the reward of this pioneer work in the field of generating-plant development. In the near future more particulars of this equipment will doubtless be available, but the outline printed in the news columns of this issue challenges one's interest because of the ingenious use of high-pressure and medium-pressure turbines, high-pressure and medium-pressure boilers and skillfully arranged superheaters that is proposed.

The thermodynamic analysis of these problems offers a fascinating and intensely practical field of study; the prospective economies of these units and the metallurgical progress which must be in reach to insure guarantees of commercial success in such a radically advanced development arouse the curiosity of the engineer and the utility executive alike, and the pioneering spirit of the Boston company, its consultants and the equipment builders deserve the commendation of the industry. The difficulties of so great a step forward appear very formidable, but the resources of American engineers are many and are seldom found more wanting in crises of equipment development than in emergencies of operation. The whole world of engineering will wish the fullest success to these laudable efforts to set a new standard of generating-plant design before the profession.

## Relativity and the Electrical Engineer

ACCORDING to recent press dispatches, the agreement between Einstein's theory of relativity and the actually observed astronomical facts is so close that no more money will be appropriated for costly expeditions to remote parts of the earth to test this theory. It is also well known that the motion of electrons in a vacuum tube checks well with the values deduced from the theory of relativity, and that this theory gives correct results for the propagation of electromagnetic waves in moving media.

The electrical engineer of a not far distant future will be directly concerned with the motion of electrons in all kinds of vacuum rectifiers, amplifiers, oscillators, etc.; in the ionization fields around extra-high-tension conductors, and in the study of liquid and solid dielectrics. And while it would be rather optimistic to expect many of the present generation of engineers to take up the study of relativity for the purpose of using it in their work, yet the oncoming generation of engineers, or at least its ablest theoretically inclined members, should be acquainted with the possibilities of this wonderful new analytical tool.

The motion of an electron is particularly interesting from the point of view of relativity. According to this theory, the values of the intensities of the electrostatic field and the magnetic field at a point depend entirely upon the velocity of the observer himself with respect to this point. Simple equations are available which connect these intensities as measured by a stationary

observer with those measured by a moving observer. Thus, in the case of a moving electron one needs only to imagine an observer moving with it and recording his measurements. But to such an observer the electron appears stationary; there is no magnetic field, and the electrostatic field is simply radial. Now, by means of the general equations it is possible to recompute these results in terms of a stationary observer and thus obtain the space distribution of the magnetic and electric fields due to a moving electron. The results check with those obtained in the old-fashioned way, and there is a considerable economy of mental effort and of formal mathematics.

Philosophers have taught for long centuries that space and time are but phenomenal concepts of our limited minds, the channels through which we perceive the universe. They have claimed that the Absolute Being needs no time or space because it sees the whole creation directly from minus infinity to plus infinity as one idea and its harmonious realization. Such a being needs no origin of co-ordinates and no zero time. At low velocities these two channels or modes of perception of phenomena—viz., space and time—have been found by humanity to be independent of each other. There is, however, no logical inconsistency in assuming space and time to be interdependent at high velocities, especially seeing that the results based on such an assumption agree with the observed facts.

Not long ago it was shown that the complicated phenomena in electrical machinery and lines can be represented by simple kinematic models. Perhaps some one will invent a combination of sticks and cogwheels which will show to the timid mind at a glance that the amounts of space and time involved in a given phenomenon depend entirely on the velocity of the observer who is describing the phenomenon.

## Where to Stop in Adding Refinements

IN THE desire to obtain low operating expense there is always danger of investing money for refinements that increase the fixed charges more than they reduce the operating expense. Furthermore, there is always the possibility that in adopting too many refinements the tail may some day wag the dog. A truth often expressed and well known by students of economy is that the best installation is the one which has fixed charges equal to the operating expense. Of course, this statement is subject to modification as conditions develop.

The point to be made is that the most economical plant is not necessarily the one which burns the smallest amount of coal per kilowatt-hour or generates a kilowatt-hour at the least operating expense exclusive of fixed charges. Still, this is the comparison often used. The only criterion of economy is how many kilowatt-hours can be got out of a plant, year in year out, per dollar of production expense, including fixed charges. With this in view, the real engineer, before copying other practices, makes it a point to study different plant arrangements, not in the aggregate but in parts, to determine whether changing this or that equipment or arrangement would reduce the sum of the operating expense and fixed charges. More extensive emulation of this practice might shorten the procession now playing "follow the leader."

## New Thoughts on Electric Furnaces

THE electric furnace has "made good" in the production of steel in competition with other methods, but recent investigations indicate that its full possibilities in the production of alloys have not been realized. Apparently there is ground for assuming that the electromagnetic effect of the electric current has a decided bearing on the metallurgical processes which occur during refining. How much the reaction of the field on the atomic constituents of the furnace charge can be utilized is a subject for further investigation. But if there is a possibility of obtaining new or better alloys by subjecting the charge to the influence of a strong field during cooling, a remarkable opportunity exists for further furnace applications.

Experimental evidence indicates that the electric furnace does things which cannot be explained on a thermal basis. For example, forced circulation by using the magnetic field has made the induction furnace a commercial possibility, and in many other applications the mixing of the constituents of the charge is best explained by the field effect on the atomic structures.

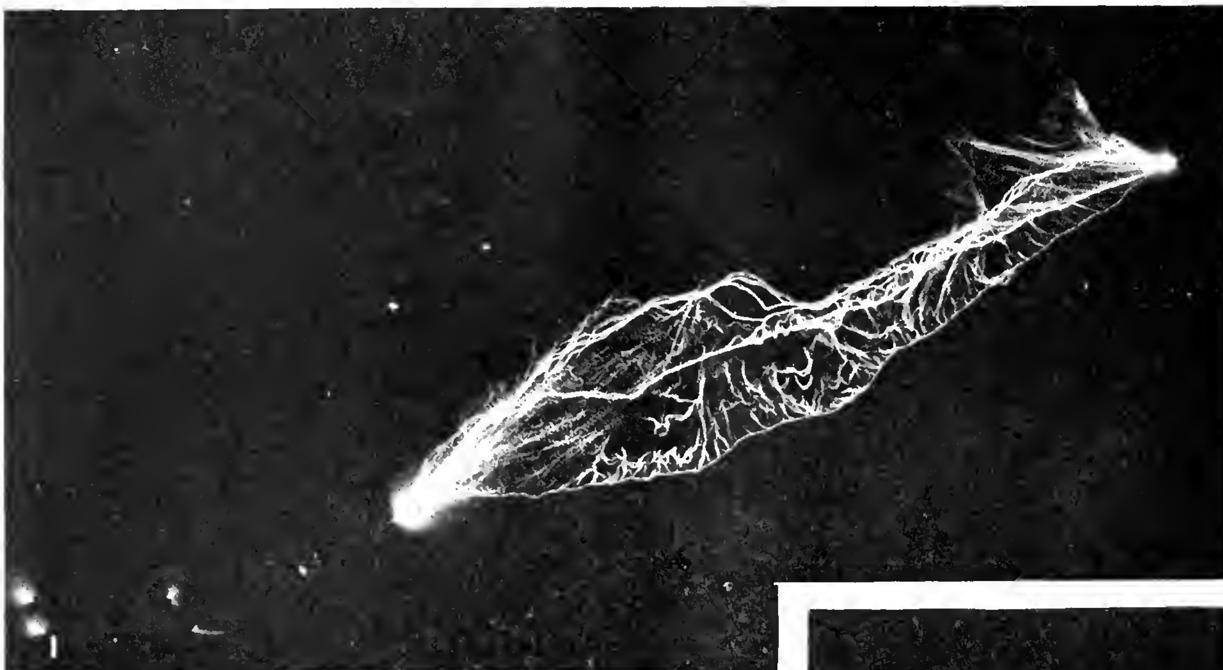
Although the subject is still rather speculative, it is quite fascinating to think that electricity may make possible the production of ferro-alloys without the use of tungsten, vanadium, manganese or other expensive constituents, and the electrical industry awaits with interest new data on the metallurgical effects which can be obtained by further work in the electric furnace.

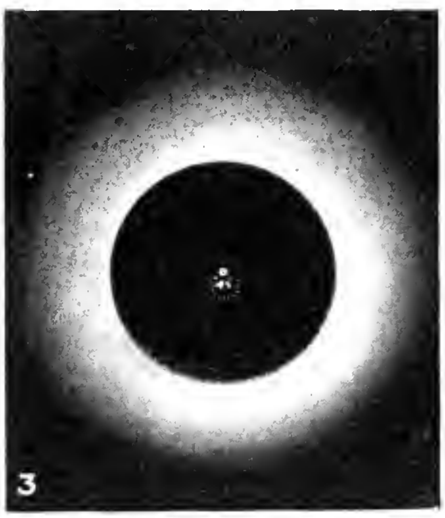
## Illinois Grading Its Utilities According to Service

A SYSTEM of grading the electric utilities of Illinois according to their service accomplishments has been adopted by the Commerce Commission of that state and affords an indication of the way in which public demands for good service are working out. Most of the state commissions have rules of some sort covering service standards, but in large degree these rules are a dead letter until insistent complaint stirs up the commission. The ceaseless inspection necessary to make them an always active force is too great a task. The Illinois grading system is intended to provide just such an active force and to forestall public complaint by removing the causes of criticism. The grading goes so far as to take into consideration the attitude of the public toward the utility and the willingness with which utilities meet complaints and remedy faults, as well as the attitude of the utility in dealing with its customers.

A great many utility men will criticise the system as an unwarranted interference with their affairs, but the impartial reader of the instructions under which the grading is carried on will be inclined to agree that a careful study of its results and appropriate action thereon will put any utility on a better footing with its own public. The instructions indicate a thoughtful and impartial effort to promote good service, and it would not be amiss if every central-station executive in the country were to have such a grading of his plant laid on his desk periodically. It would reveal surprising and disconcerting weaknesses as well as the strong and gratifying points in his organization. The Illinois grading system is not the last word in such matters, but it is worth a great deal of hard study.

# Corona Photography with Quartz Lens





THROUGH the use of quartz lenses it is now possible to study arc and corona formation much more thoroughly than heretofore. Some comparisons are made in the accompanying illustrations. Figs. 1 and 4 show simultaneous photographs of a 14-ft. 1,500,000-volt arc with a glass lens and a quartz lens. The first shows only a lace-like tracery, whereas the latter shows the ultra-violet light as well. Figs. 2 and 3 are fifteen-second exposures with glass and quartz lenses. The latter shows corona extending 27½ in. beyond the 36-in. circle, whereas the glass lens shows only brush discharge. These photographs were taken in the Pittsfield research laboratory of the General Electric Company.

### Operating Experience Presented in Notable Papers — Grounding Devices, Relays, Furnaces, Insulators, Railroad Electrification and Illumination Discussed from Practical Standpoint

THE unprecedented expansion in the light and power industry was reflected in the atmosphere at the Pittsburgh meeting of the American Institute of Electrical Engineers on April 24-27. A spirit of optimism and expansion was current, and the successful program and skillfully conducted convention accented the feeling of confidence in the future of electric power. Nearly twelve hundred engineers assembled from widely separated properties and discussed the technical features of equipment and the practical features of operation associated with transmission, distribution and utilization of electric power.

The papers and the discussions clearly indicated the ability of the engineers in the light and power industry to meet the present and future engineering problems connected with a greater use of power on a national scale. Many heretofore controversial questions were recorded as answered, and the thoughts of the engineers were directed toward new problems and toward new equipment.

## *Operation of Grounded Systems*

The trend of present practice, as reported by the sub-committee on grounding of protective devices (E. C. Stone, chairman), is definitely toward the grounding of neutrals on large transmission systems. This conclusion was drawn from an analysis of thirty-six systems having an aggregate generating capacity of 6,371,850 kva. and a transmission mileage of 31,408. Increasing mileage and voltage have been the factors necessitating the practice described. On systems transmitting at generated voltage the neutral usually is grounded at each generating station with resistance of low value. On systems transmitting at higher than generated voltage the neutrals of the transformers are dead-grounded at each generating station and some or all substations. Where resistances are used they are generally made up of cast-iron grids with time ratings at maximum current of thirty seconds to sixty seconds.

On systems transmitting at generated voltage the relation between the voltage and value of neutral resistance is fairly consistent and is usually identical with the maximum ground fault current which could exist, assuming that the resistance and reactance of the return circuit from fault to ground connection was zero and that the voltage at the fault was held at normal. When ground relays are used the neutral resistance is generally higher than when using phase relays.

In the last few years there has been a fairly marked trend toward the use of higher resistance in grounded neutrals, especially in the higher-voltage systems. This has led to the development of a number of relay schemes in which selective operation of breakers is obtained with ground currents less than the full-load current of the line. Six companies are using schemes of this nature on parts of their system.

The most recent development in methods of ground-

ing of neutrals is the use of reactance instead of resistance. If for any given system the reactance is properly proportioned it will exactly neutralize the capacitance of the transmission system to ground, so that in case of a grounded phase no current will flow through the fault.

The use of arc suppressors has been very generally abandoned. That is not because such apparatus was without merit, since some fairly good results were obtained with its use, but rather because of the development of breakers of high interrupting capacity and selective relays, which are found to be a better solution of the problem.

In studying the effects of heavy ground currents on the operation of synchronous machinery a series of tests was made by one of the manufacturers under conditions approximating those of a certain transmission system. The results of this test indicate that the average voltage at the motor could not drop more than 30 per cent without interference with operation.

Grounding the neutral has proved successful to a very high degree in limiting trouble from excessive voltage on transmission systems. Case after case is on record where frequent and destructive insulation breakdowns on systems operating underground have been virtually eliminated after the neutral has been grounded.

General considerations in grounding the neutral of transmission systems were the subject of a paper by H. H. Dewey. The author pointed to the fact that in grounding overhead systems the tendency is toward the use of low resistance values, while in underground cable systems the trend is toward the use of resistance in the ground connection. The general conditions on the two systems are very similar, and the author thought there were no very good reasons for the differences in grounding practice.

Different types of resistance for the grounded neutral were considered, and the general conclusion was that on any large transmission system high-voltage strains are more to be feared than high-current strains.

SUMMARY OF GROUNDING PRACTICE

| | Systems at Generated Voltage | Systems at Higher Than Generated Voltage | All Systems |
|---|---|---|---|
| Number of companies | 20 | 32 | 36* |
| Number of systems: | | | |

* Some companies operate both types of system.

A descriptive performance of the Petersen coils installed on the system of the Alabama Power Company was embodied in a paper on "The Neutral Grounding Reactor" by W. W. Lewis. This paper discussed the theoretical features surrounding the use of a reactor on ungrounded systems and gave the results of tests made on the installations in Alabama at the time the reactor was installed. The reactor used has no core, is oil-immersed, water-cooled and designed to operate continuously at 795 kva. with 55 deg. C. rise. The total loss in the reactor at full voltage and maximum current is about 21 kw.

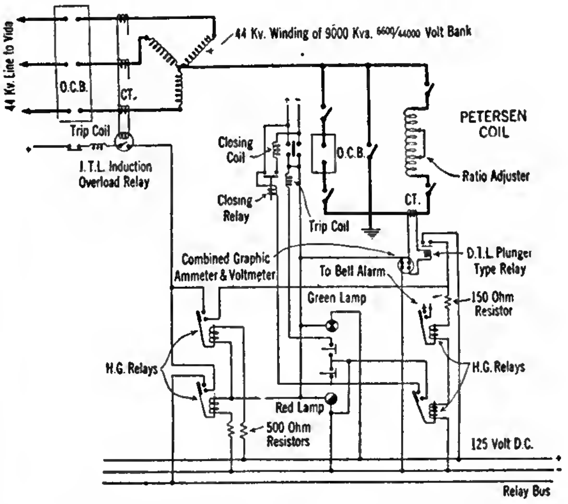
The resonance point of the circuit was determined in two ways—first, under normal conditions with no conductors grounded; second, when one conductor is grounded. Several series of arcing tests were made totaling about fifty arc-overs, and in this series of tests the arc was extinguished in from 5½ cycles to 14 cycles. Detailed data and oscillograms were made of the conditions under test which showed that the reactor functioned very well for the system upon which it was installed. Calculations showed that the current to ground when one conductor of a three-phase system is grounded is about one and a half times the normal three-phase charging current. Tests on the system showed that if the system had a ground wire the ground current was increased about 20 per cent. The arc-over test showed that the reactor would function to extinguish the arc with considerable tolerance in the setting. From the standpoint of voltage stresses the system with the reactor is more like an isolated neutral system than a grounded neutral system, except that the excessive voltage rises due to arcing grounds which occur on an isolated neutral system are eliminated. There is a possibility of overvoltage when the arc breaks, due to a difference between the resonant and supply frequencies, provided that the reactor serving is not in exact resonance. In the opinion of the author of the paper, the device will be limited to comparatively low-voltage lines of moderate length; that is, perhaps, up to 66,000 volts, or in a few cases up to 100,000 volts if the length of line is short. The reason given was that the current to the reactor is affected by the line reactance. Thus on long lines and high voltages it is probable that the residual current would maintain the arc. The author thought that the device appeared most applicable to those systems which are now operating isolated neutral and which for some reason connected with the operation or apparatus do not wish to go to a solidly grounded neutral.

### PETERSEN COIL REDUCES INTERRUPTIONS DUE TO INSULATOR FLASHOVERS

According to a log of Petersen coil operation kept by the Alabama Power Company since Nov. 16, 1921, the Petersen coil has considerably reduced the number of interruptions due to insulator flashovers during lightning storms. This assertion was made by J. M. Oliver and W. W. Eberhardt in their paper on the subject. For example, during 1921, before the Petersen coil was installed, there were forty-three interruptions due to lightning, which caused the line to be out of service a total of 230 minutes. In 1922, when the Petersen coil was in service, there were only seven cases of interruptions due to lightning, or a reduction of 83.5 per cent, with the line out of service only fourteen minutes, or a reduction of 94 per cent.

However, the use of the Petersen coil is attended by

the disadvantage that the taps have to be changed for virtually every switching operation, so that the inductive reactance of the coil will always be in resonance with the capacity reactance of the line to ground. Furthermore, several bus insulator flashovers occurred



PETERSEN COIL CONNECTIONS (OLIVER AND EBERHARDT)

A definite-time-limit overcurrent relay is connected in the secondary of a current transformer the primary of which is in series with the Petersen coil and ground. This relay is given a time setting of approximately two seconds. Normally the flashovers are cleared by the Petersen coil in five to fifteen cycles; consequently, when an abnormal current persists for several seconds, it is evident that the reactor is not functioning. At the end of two seconds the relay will close, thereby energizing two auxiliary relays, one of which causes the grounding switch to close and the other to ring an alarm bell. The grounding switch on closing short-circuits the reactor and the regular overcurrent relay scheme comes into action to clear the trouble.

when line switching was performed while the Petersen coil was in service. Whether the coil was in any way responsible for the flashovers is not known, but as a precaution against similar trouble in the future, the line relay has been electrically interlocked with the control circuit of the grounding switch to insure that the latter shall be closed before the line switch can open on relay action. However, this has the disadvantage of slowing up the relay operation when clearing a short circuit.

During the period covered by the log there were 168 operations of the Petersen coil, of which only two could be strictly classed as faulty. In these two cases the flashover held on long enough to close the grounding switch and cause the overcurrent relays to open the line. The line went back into service properly in each case, indicating that the trouble was not a solid ground but a flashover which the Petersen coil evidently failed to clear. There was a total of twenty-nine cases of solid grounds and phase-to-phase short circuits due to line, transformer and bus trouble, which are outside of the operating sphere of the Petersen coil. However, all these were successfully cleared by the line relays. In three of these cases, however, after the line switch opened, a string of the five suspension insulators on the 44-kv. bus between the transformer and the line switch flashed over, indicating the presence of an unusually high voltage. Since the insulators tested satisfactorily, it seems that some high-voltage transient was introduced by the disconnection of the line capacitance. It is proposed to make further tests to verify this point.

In seven operations the grounding switch closed but no line switch opened and no disturbance occurred on the system. This action indicated a solid ground on the system, which evidently held on long enough (two seconds) to cause the definite-time-limit overcurrent relay to operate, but cleared before the contacts of the grounding switch closed.

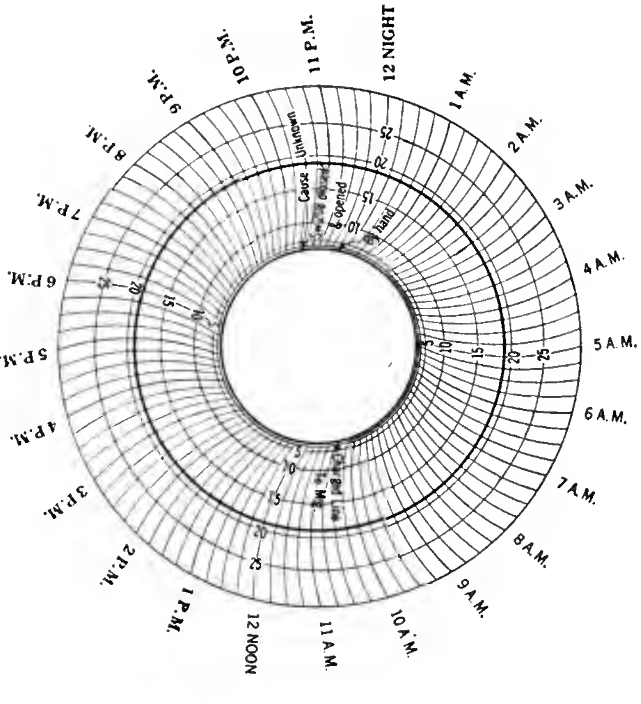
Twenty cases of reactor-current indications coincident with switching operations on the lines were observed when the neutral current must have been zero. These indications may have been due to the failure of all three poles of the oil-circuit breaker to open or close simultaneously, thereby causing a shift in the neutral.

While the experience of the Alabama Power Company indicates that the Petersen coil may prevent arcing grounds on grounded-phase operations, it is hardly safe to take the risk, as the imposition of full-line voltage to ground on the ungrounded phase for a considerable length of time will aggravate the trouble. With grounded-phase operation eliminated, the Petersen coil need have only a two-minute rating as compared with a continuous rating and would be less costly.

Other points which the experiences recited brought out were that all insulator pins should be grounded in order to insure the best positive action of the coil; that all switching, both hand and automatic, should be done with the Petersen coil out of service—viz., with the neutral solidly grounded—and that grounded phase operation is not advisable.

Considerable discussion arose at the Tuesday afternoon session regarding the relative merits of low and high resistance grounds, some advocating low resistance to secure enough current to operate selective relays and others favoring higher resistance to minimize disturbances. It appeared to be the consensus of opinion that the Petersen coil is limited to short branch lines.

Different problems are involved in grounding cables and overhead lines. R. W. Atkinson pointed out that it is feasible to insulate overhead lines for overvoltage,



GRAPHIC RECORD OF COIL OPERATIONS (OLIVER AND EBERHARDT)

but hardly so with cables. Furthermore, cable has greater electrostatic capacity than open wires. As indicating the success of the solidly grounded neutral, Mr. Atkinson referred to a 33,000-volt cable installation in Los Angeles which has operated two years.

F. C. Hanker pointed out that the Montana Power

Company reversed several years ago its opinion that the size of a grounded neutral system is limited. From the evidence presented it is very apparent, said Mr. Hanker, that the use of the Petersen coil is very limited.

The great diversity of opinion on grounding was dwelt upon by J. B. Taylor. In some cases large currents are allowed to avoid voltage surges, and sometimes vice versa. Besides, there are differences of opinion on the value of resistance to use. There is no virtue, he contended, in clearing a fault by allowing a great rush of current just because the equipment will withstand it. Such practice may in time weaken parts of the system. The most important factor in grounding is the calculation of the resistance; this should depend on the switch settings.

L. P. Ferris called attention to factors which should have serious consideration in grounding. For example, triple harmonics occur in grounded neutral systems which may disturb adjacent telephone lines. The possible bad effect of multiple grounds was also emphasized. Y-Y connections are very undesirable, but fortunately their number is limited. Mr. Ferris said that it is very gratifying to notice that the Petersen coil reduces interruptions, since otherwise the short-circuit currents developing from faults would produce acoustic shocks. Such shocks could be reduced still more if a resistance were connected in series with the breaker which is used to short-circuit the Petersen coil when it fails to function. The current experienced when the Petersen coil is set for resonance, he explained, is apparently due to the unbalanced voltage resulting from unbalanced arrangement of lines to ground. This condition can be corrected by balancing from neutral to lines.

H. W. Smith recommended rating ground resistors at 600 deg. since at this temperature they would have the safety factor which comes from change of resistance with temperature. As systems operating at generator voltage increase in size they must come to grounded neutrals, he contended, and hence should be laid out with this in view.

In explanation of the apparent voltage surges which occur when switching operations are carried on with the Petersen coil in circuit, H. M. Trueblood said: "If there is more reactance than necessary for resonance when three phases are connected, and if by chance one phase of a breaker fails to open simultaneously with the other phases, then voltage surges will occur. Hence care should be taken not to have more reactance connected in the Petersen coil than necessary."

The problem when using the Petersen coil, declared H. H. Dewey, is to secure the proper balance of inductance and capacitance, particularly on long high-voltage lines. Hence the Petersen coil is chiefly adapted to short branch-circuit lines.

R. D. Evans contended that the application of the Petersen coil is reaching its limit on the Alabama system, according to the data obtained. He warned against changing from a free neutral system to Petersen-coil protection without providing for the conditions imposed by grounded neutral operation.

There is more necessity of grounding frequently on high-voltage lines than on others, maintained C. L. Fortescue. Grounding reduces the cost of transformers, he explained.

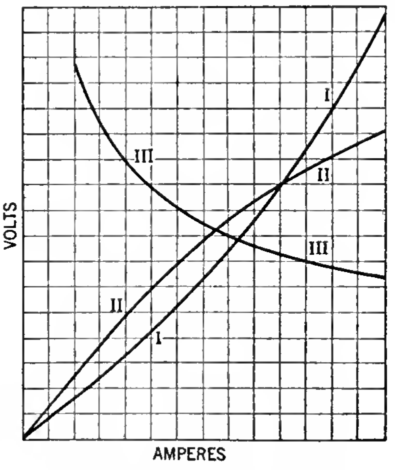
No one system of grounding is suitable for all conditions, J. Allen Johnson pointed out. Power lines with greatest exposures must use higher ground resistance to minimize interference. With induction-type selective relays, he explained, one cannot rely on their current settings as much as on their time characteristic when grounds occur. Just because a system can withstand short circuits is no reason for subjecting it to them in order to clear grounds. For protection against such faults he advocated ground relays.

L. F. Blum advocated transposing transmission lines, reducing power losses in Petersen coils and detuning to get the best protection from this system.

In closing, Mr. Dewey cited several examples where multiple grounds have not produced serious disturbances.

# *Technical Features of Surges and Arcing Grounds*

Dr. Charles P. Steinmetz, in a paper entitled "Frequency Conversion by Third-Class Conductors and Mechanism of the Arcing Ground and Other Cumulative Surges," discussed the building up of high-voltage oscillations in power circuits which differ from the typical transients of energy readjustments in that they do not gradually die out but increase in intensity until either destruction occurs or they finally limit themselves. These surges, of which the arcing ground is typical, derive their energy from the machine power of the system and so constitute a frequency transformation of which the mechanism has been little understood. Dr. Steinmetz derived the equations of the circuits of this character on the basis of a physical conception which considers a negative resistance in combination with the source of power which supplies the energy given out by the negative resistance. The so-called "third-class conductors" are those in which the voltage decreases with the increase of current, and the author showed that these conductors can be considered as a combination of the negative resistance with a source of power and as such are capable of transforming the low circuit frequency into a high oscillation frequency of alternating current. Their presence in an electric system may in this way produce cumulative oscillations.



CHARACTERISTICS OF CONDUCTORS

I—Metallic conductors. II—Electrolytic conductors. III—Arcs as conductors. (Steinmetz.)

The general equations in the paper were based on a system comprising a third-class conductor shunted by an inductive circuit containing capacity and supplied with voltage over an inductive circuit from an alternating low-frequency source, and the author showed that in such a system current and voltages of two distinct frequencies may continuously exist, of which one is the fundamental circuit frequency and the other a high oscillation frequency. The voltage at the high oscil-

lation frequency is limited only by the resistance of the oscillating circuit and may build up to very high values, particularly in the transformer. Thus the cumulative surge of the arcing ground in a transmission line does not reach such excessive values as that in the high-voltage coil of the power transformer, but may be of moderate intensity of the magnitude of the normal line voltage.

### EXPERIMENTAL OBSERVATIONS DETERMINE THEORY OF ARCING GROUNDS

Pointing out that the primary reason for operating transmission systems with a grounded neutral is to alleviate the destructive effects produced by arcing grounds, J. F. Peters and J. Slepian presented a paper on the arcing ground and the theory underlying its operation. The paper is based on laboratory experiments which duplicate arcing grounds. These elaborate experiments substantiate the theory which, when applied to a three-phase system, calls for displacement of neutral relative to ground and the development as a result of transient oscillations of maximum voltage three and one-half times normal voltage to neutral on the sound phases and two times normal voltage to neutral in the grounded phase. In a grounded neutral system with low impedance between neutral and ground the charge will be drained off before the next arc strikes and the maximum voltage which will be developed will be two and one-half times normal and one times normal at the same points stated previously. Thus the maximum voltages developed by arcing grounds on isolated neutral and grounded neutral systems respectively are in the ratio of three and one-half to two and one-half. This does not consider, however, the effect of sudden changes of voltage distribution in the interior of apparatus connected to a system in which the effect is much greater in the isolated neutral system. Thus the surges set up by the arcing grounds must be considered as a source of danger to the connected equipment.

Dr. J. Slepian, in the discussion of arcing grounds, took exception to the mathematical treatment of the arc and its negative resistance properties in Dr. Steinmetz's paper, saying that there was a lack of definite mathematical statement of the nature of the arc which made it necessary to go through the mathematical treatment and pick out the assumption. He said that the assumption for low-frequency arcs seems to be on the basis of straight-line characteristics, while for the high-frequency arcs a time lag assumption is brought in that gives the characteristic curve as an ellipse. With these deductions from the paper, Dr. Slepian questioned the reasonableness of the figures in the practical examples assumed by Dr. Steinmetz, saying that the negative resistance figures were too high. In place of the assumed value of 120 ohms he gave 20 ohms as a more reasonable assumption for the value of negative resistance. He claimed that the value used gave results that are impossible in any arc encountered in practical experience.

E. E. F. Creighton, using the analogy of a violin string, pointed out that many arcs over insulators or from conductors to ground might occur without serious consequences, but that an arc from a point on a line where the frequency of the disturbance corresponds with the natural frequency of the line or some piece of apparatus might cause a large amount of damage. He went on to illustrate by citing an example of a furnace installation that had operated successfully and had been enlarged by the addition of three transformers to the original three. It was then found impossible to keep all six transformers in sèrvice, owing, as was later discovered, to resonance between the frequency in the arc and the natural frequency of the transformer coils which resulted in small arcs forming between turns and ultimate serious breakdowns. Mr. Creighton also gave as the reason why the arcing ground suppressor had not proved successful, and why the Petersen coil would not, the close adjustment required of the apparatus to system conditions to enable either of them to function successfully. So close is this adjustment that it is impracticable to keep such devices adjusted to momentary changes in system conditions.

W. A. Hildebrand asserted that the voltage factor is not fundamental and that the high-frequency factor, which has no relation to 60-cycle characteristics, has been largely overlooked in the studies of arcing grounds.

C. L. Fortescue said that Dr. Steinmetz's ideas should be carried out to give more plausible values and that the papers presented show the need of more study, not under laboratory conditions but on a large scale.

H. R. Woodrow, in discussing the paper of Messrs. Peters and Slepian, said that maximum potentials were given but that system absorption had been neglected. Normally, he said, smaller values, particularly on underground cables, would be experienced.

That the figures of experts could not be checked by the experience of a Georgia company was asserted by E. P. Peck, and that one line 65 miles long operating at 60 kv. had developed surge voltages over 180 kv. was certain. The trouble had been cured by grounding the neutral through good grounds. Lately the same class of troubles have been cured on a Utica (N. Y.) property by solidly grounding the generator neutral.

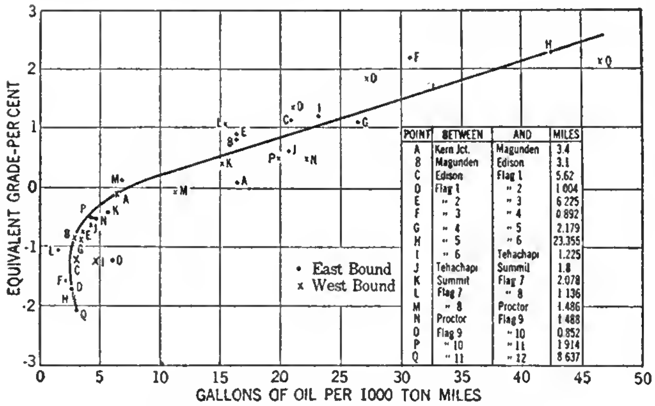
## *Furnace Operation and Electrification*

Test data on a representative mountain railway on the West Coast showing the fuel consumption of an average mountain-type locomotive burning oil were presented by A. H. Babcock in his paper on "Some Fuel Determinations on the Southern Pacific System." The paper contained a complete record of fuel consumption, beginning with firing up at the engine house and the standby consumption while the engine is waiting outside the house for the train, and including consumption while testing brakes, during acceleration, running up and down the various grades, holding the trains on sidings and finally running down hill over stretches of steep grade.

The over-all efficiency determined by the test was 5.57 per cent. It is the ratio of the integrated foot-pounds of work done by the engine whenever the draw-bar pull was positive to the total energy in the fuel used over the same time. From the test it is apparently constant for all grades greater than 0.5 per cent. The average operating efficiency rated on eastbound and westbound travel was 92.5 per cent, with an average thermal efficiency of less than 6 per cent. The ratio of the revenue freight weight to total train weight was 0.743, and in making comparisons this factor must be considered. The resultant data apply, in the opinion of the author, to the specific conditions, and should not be applied indiscriminately to all conditions of operation.

Dr. Cary T. Hutchinson, in an analytical discussion,

pointed out that Mr. Babcock's analysis was not general in scope but limited to the determination of the oil used on the particular section of the Southern Pacific under the conditions of service ruling there. Furthermore, no drawbar-pull measurements were made, so that figures for efficiency were based on calculations of work done from the profile of the section under the specific assumptions of the author.



FUEL CONSUMED PER 1,000 TON-MILES ON VARIOUS GRADES (BABCOCK)

Mr. Hutchinson then assumed to replace the steam locomotive with a four-axle, 110-ton electric locomotive for a 750-ton trailing weight and assumed an efficiency from power house to locomotive drivers of 63 per cent and then calculated the comparison between steam and electric operation, arriving at results given in Table I.

TABLE I—WORK DONE AT DRIVERS, STEAM DRIVE

| | Eastbound | | Westbound | |
|---|---|---|---|---|
| 1. Weight of train, tons | ...... | 1,000 | ... | 1,000 |
| 2. Work at drivers, kw.-hr.: | | | | |
| (a) Grade | 2,760 | | 985 | |
| (b) Curve | 250 | | 25 | |
| (c) Track | 690 | 3,700 | 240 | 1,250 |
| 3. Available for regeneration, (a) — (b+c) | | 1,820 | | 720 |
| 4. Delivered to contact system, 75 per cent | | 1,365 | | 540 |
| 5. Deliverable at driver, 80 per cent | | 1,090 | | 430 |
| 6. At driver as per cent of total work | | 29.4 | | 34.4 |
| 7. Same, for round trip, same tonnage both ways | | 30.6 | | |

He then assumed that 30 per cent of the total requirement is furnished by gravity and 70 per cent by power station, and concluded that the relative energy requirements for a round trip are as shown in Table II.

TABLE II—RELATIVE HEAT REQUIREMENTS, STEAM AND ELECTRIC, FOR SAME SERVICE

| | Steam | Electric |
|---|---|---|
| 1. Weight of train, tons | 1,000 | 860 |
| 2. Energy at driver, total kw.-hr | 4,950 | 4,250 |
| 3. Energy at driver, from oil, kw.-hr | 4,950 | 2,970 |
| 4. Energy at driver, from oil, per cent | 100 | 60 |
| 5. Heat required at drawbar per kw.-hr., B.t.u | 109,000 | 45,500 |
| 6. Total heat required, ($10^6$xB.t.u.) | 540 | 135 |
| 7. Total heat required, per cent | 100 | 25 |

Mr. Hutchinson then concluded as follows:

"This means that, in comparison with the author's test result, electric drive would reduce the fuel required by 75 per cent—a ratio of steam to electric of four. If allowance be made for the difference between tests and service conditions, this ratio will be even greater. These results are in practical agreement with the estimates of the superpower report."

N. W. Storer said that 7 lb. per ton was too high a train resistance for a whole run, so the work calculated was more than would be the case. He also questioned the accuracy of determination of locomotive resistance.

W. J. Davis pointed out that the results were better than could be expected from a coal-fired locomotive, stating that the cinder loss varied from 10 to 18 per cent in coal-fired locomotives with the rate of coal burning varying from 100 lb. per square foot per hour to 125 lb. per square foot per hour.

Mr. Davis' principal point was that, even though there were fuel savings, the fixed charges of electrification might easily offset them, but that the chief reason for electrification still existed in the advantages in conducting transportation. He cited increased capacity of tracks, reduction of overtime, very great savings in locomotive repairs per locomotive and reduction of number of locomotives—because the average steam locomotive was available for service only 25 per cent of the time, whereas the average electric locomotive was available 95 per cent. Mr. Davis concluded that because of greater serviceability and because electric locomotives could be made larger, one electric might actually replace four to five steam locomotives. Thus, said Mr. Davis, even with the fuel saving counterbalanced by fixed charges, by the saving in maintenance of locomotives, in maintenance of ways and structures and in wages total transportation economies of 25 to 50 per cent might be realized.

Mr. Twogood, in replying for Mr. Babcock, said that they had tried all sorts of mathematical analyses and could come to no other conclusion than the one given. He admitted that fuel was not the determining factor. He pointed out that operating officials were interested in the weight of the locomotive as well as of the train because eventually it was net revenue freight which paid the bill.

Through a large number of observations the author of the paper on "Some Problems in Electric Furnace Operation"—F. V. Andreae, chief engineer Southern Manganese Corporation—was led to believe that the transformation of electrical energy into heat energy in the furnace takes place in an arc passing through an atmosphere of vapors under pressure. The properties of the arc vary with the different materials. The current will increase when the arc is shortened under constant voltage and for constant currents, and the voltage

THEORETICAL ELECTRICAL CONDITIONS IN ELECTRODE LEADS OF VARIOUS TYPES FOR 4,000 KV-A. ELECTRIC FURNACE

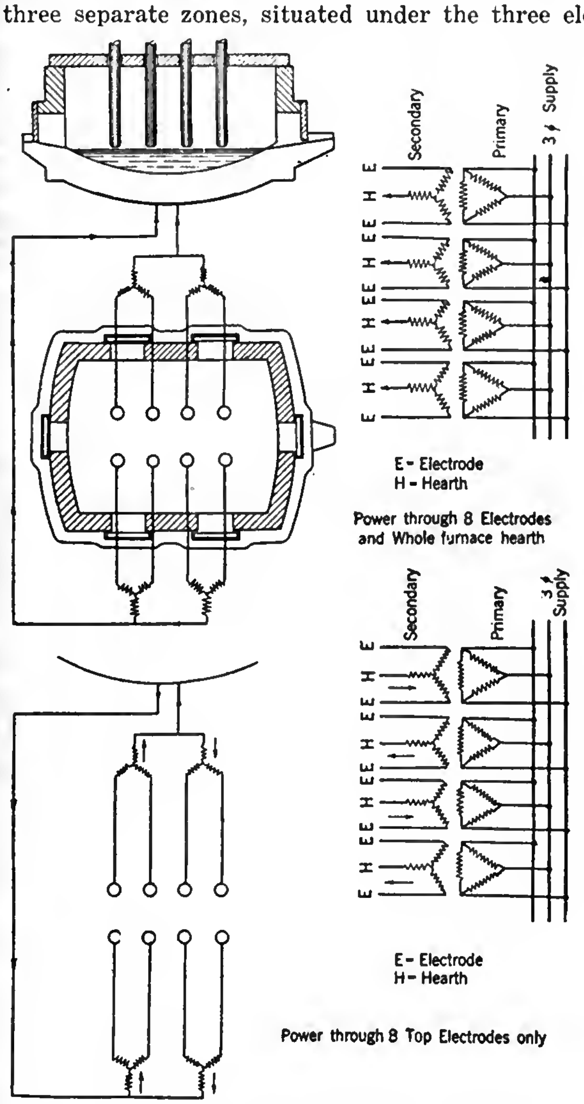
ANALYSIS OF ELECTRODE LEAD PERFORMANCE (SAKLATWALLA AND ANDERSON)

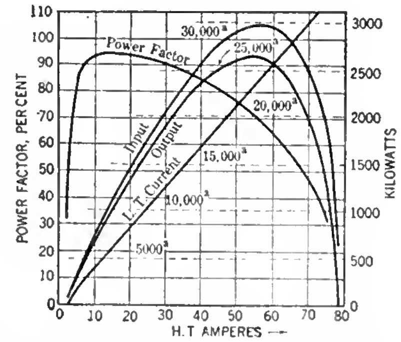
across the arc will increase with increasing length. Based on the theory that the reactance of a three-phase electric furnace does not depend on the load, but does depend on the arrangement of the conductors, the author derived a general equation for the furnace. He showed that, owing to the fact that the main conductors carrying the current from the interlaced busbars to the furnace are more or less in one plane, a transformer action is introduced between phase 1 and phase 3, taking power away from phase 1 and transporting it to phase 3, the phase rotation being 1 to 3. This power may be considerable. Moreover, when voltages between phases and currents are balanced the power delivered by the three electrodes is quite unbalanced, a fact that is very apparent in large furnaces, electrode 1 seeming dead while electrode 3 takes most of the power.

The load in the furnace is considered as connected in star, the bottom of the furnace being the neutral. The electrical energy is transformed into heat energy in three separate zones, situated under the three electrodes, and the load resistance is probably furnished by an arc in an atmosphere of the vapors under pressure. The author took up specific examples of the application of the general equation and showed how the unbalance can be taken care of in several ways. He reached the conclusion that the general performance of the three-phase furnace can be determined in advance with a large degree of accuracy by using the simple equations of the balanced three-phase system, where the only thing that is necessary is the previously determined reactance per phase, which is an important characteristic of the furnace.



60-TON TO 80-TON FURNACE DESIGNED FOR FORD MOTOR COMPANY (HODSON)

Electrical factors to be considered in the design of leads for ferro-alloy electric furnaces in order to achieve the highest input efficiency were discussed in the paper by B. D. Saklatwalla and A. N. Anderson. They also described a new system of electrode control which consists of Kelvin balance actuating relays which in turn control the operation and direction of rotation of the motors operating the electrodes. Information was also given on a new electrode holder to curtail the time of making changes.



PERFORMANCE CHARACTERISTICS FROM CIRCLE DIAGRAM (ANDREAE)

The authors reached the following conclusions:

1. The larger the cross-section of the conductor the larger the skin effect. This effect is appreciable at frequencies of 60 cycles for conductors greater than ½-in. diameter.

2. Skin effect is higher in straps than in tubes of equisectional area with subsequent higher power loss.

3. Distribution of the current over the sectional area is not affected by the inductive disposition of the conductor, since the internal inductance is unaffected by the mutual inductances.

4. Inductive reactance may cause considerable voltage drop in the electrode leads.

5. The larger the diameter of the conductors the less the inductance.

6. The farther apart the conductors the larger the inductance.

7. When inductive reactance expressed as per cent reactance drop amounts to 20 per cent or more, the actual volts drop in the line increases rapidly with decreased power factor.

The nearest approach to the tubular form of conductor for flexible leads is the familiar asbestos-cored extra-flexible cable developed expressly for furnace operation.

The development of the large electric melting furnace, the limitations of large electrode furnaces and the design and construction of the largest electric melting furnace ever built were subjects covered in a paper by Frank Hodson. He also discussed the advantages of correct heat application, the influence of the new Soderberg continuous electrode on furnace design and the possibility of using large electric furnaces as an intermediate process for the manufacture of cheap steel.

The Greaves-Etchells furnace as finally developed may be described as an arc-resistance furnace which on normal operation introduces two phases of the three-phase power supply through two or more top electrodes and the third phase through the whole of the furnace

hearth. On all recently installed furnaces of this type with four or more electrodes the system and design permit of the whole of the power being derived through the top electrodes or by change of position of an oil switch through the top electrodes and the furnace hearth, a balanced load being obtained with either method. This arrangement gives the furnace considerable flexibility of operation, as the top electrodes and high voltage can be used when melting down or when starting up the cold furnace, and the top and bottom contacts when a molten bath is obtained or for refining and superheating.

The new Soderberg electrode consists of a thin metallic casing the size of the electrode to be used, into which the electrode paste or mix is dropped. The actual baking of the electrode is done in the furnace.

A diagrammatic plan and elevation of the 60-ton to 80-ton furnace designed for the Ford Motor Company, Detroit, is shown in the accompanying illustration. It will be equipped with eight electrodes and transformers of 12,000-kva. capacity. The electrodes are arranged in two rows of four, and each pair and contact plate under the hearth of the furnace, which is common to all, form an electrical unit and are supplied by a 3,000-kva., three-phase transformer. By means of a switch power can, if desired, be derived entirely through the top electrodes. When this is done the bottom connections are thrown in series, and consequently no current can flow through the hearth.

### Furnaces Used in Making Alloys

The assertions regarding the sizes of arc furnaces in Frank Hodson's paper were questioned by W. E. Moore, who said that there was no reason why other types of arc furnaces should not be made in larger than 40-ton sizes. He characterized the ideal furnace as a one-electrode, single-phase type, but said that the power companies would not tolerate such a furnace. He said that 24-in. electrodes are not the largest available, as at least 32-in. electrodes are in use and 36-in. are made for the Soderberg type. Both Mr. Moore and F. W. Brooks criticised Mr. Hodson's advocacy of the conductive bottom, asserting that it is a weakness in furnace design. Mr. Brooks said that acid bottoms will not conduct current at voltages used in steel furnaces and that conductive bottoms can therefore be of basic material only, and these will not stand up under the heat involved. Mr. Moore questioned Mr. Hodson's statements regarding balance, stating that the variable resistance of the conductive bottom produces unbalance. He also characterized Mr. Hodson's statements regarding distributed heat as having a backward tendency, because it is necessary to keep electrodes as far away from the furnace refractory linings as possible in order to keep down temperatures.

E. T. Moore said that F. V. Andreae's paper had given undue attention to balanced loads between conductors and other parts of the apparatus and that the determining factor is the distance of the electrodes above the bath. Fluctuations, rather than load unbalances, he said, were detrimental to the central station. He also said that the Kelvin balance method described by Messrs. Saklatwalla and Anderson was not necessary in all types of furnaces. To this and a point about the effect of charging on load balance raised in the discussion Mr. Saklatwalla replied by outlining the continuous and uniform method of charging with finely divided and well-mixed material employed in the ferro-alloy processes in which the furnace is used. This, he said, made the wattage-input control method superior to voltage and amperage control. E. T. Moore took issue with the assertions of Mr. Hodson about the induction furnaces, expressing the opinion that with the advance of the art and availability of low-frequency current small induction furnaces have been developed and successfully used and large ones are within the realms of possibility.

### Heating a Cotton Weave Shed by Electricity

Electricity is used exclusively for heating the St. Croix mill of the Canadian Cottons Company, Ltd., Milltown, New Brunswick, Canada, which operates 56,880 spindles and 1,448 looms. The equipment used for heating this mill was described in a paper by C. T. Guildford, who also outlined the calculations made to estimate the quantity of heat required for buildings of this kind. Computations were presented to show the conditions under which electric heating in a textile mill may be used.

The method of heating adopted is the Sturtevant hot-air system with groups of electric heating units instead of steam coils in the fan room. The weave shed, which is a one-story building, 480 ft. long x 182 ft. wide, requires 1,600 kw. consumption at 15 deg. below zero, which with the equipment installed leaves a reserve capacity of 463 kw. for further drop in temperature. According to tests made, the room temperature can be quickly brought to any desired value by connecting additional heaters. The actual heat input checks very closely with the calculated requirements. The author concludes that electric heat should be purchased at an estimated cost of $0.0025 per kilowatt-hour to be on a parity with coal at $10.50 per ton where the average temperature is 22 deg. during the heating season. With coal at $5 per ton, as in parts of the South and where the average heating season temperature is 48 deg., electric heat should be purchased at $0.00156 per kilowatt-hour. Electric heat may be adopted with economy in mills where surplus hydro-electric power is available. In the case of the plant at Milltown a return of more than 37 per cent on the investment for the electrical equipment is shown, and in a plant in Georgia a return of over 18 per cent can be realized. The average heat required during the night for the Milltown installation was found to be 44 per cent greater than that required during the day, even after due allowances were made for the heat supplied by power and by the operators.

### Should Compare Steam and Electric Heating on Proper Basis

That electric and steam-heating systems are not comparable on the basis of heat units furnished for heating purposes was the opinion of Wirt S. Scott in discussing C. T. Guildford's paper on electric heating of a cotton-weave shed. He said that 50 per cent of the heat supplied from a steam-heating system is conducted out of a building because of the location of radiators near windows or similar openings. In the case discussed in the paper Mr. Scott said that for steam heat a change in air of four times per hour had been figured, while for electric heat only once in two hours had been provided for. He emphasized the importance of heat given off by motors and other power equipment in considering such a heating problem. In the case of the Canadian plant this amounts to 600 hp. in motors. During

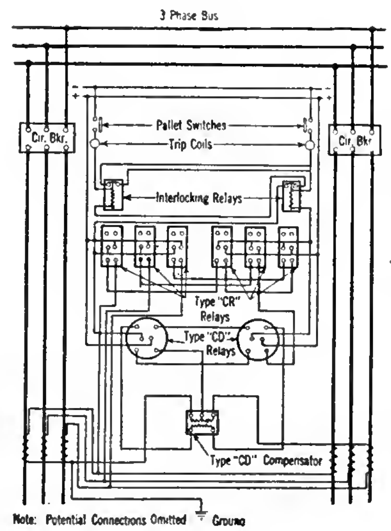
cold winter nights, with no motors running and with outside temperatures 20 deg. below zero, he said that the sixteen heating circuits with a capacity of 2,200 kw. may be required to keep the rooms at 70 deg. During the day, with somewhat higher temperatures outside, six of the main heating circuits usually keep up the room temperature. An adjustment of the automatic control of one circuit with a capacity of 137½ kw. usually suffices to keep the room temperatures within one degree of the 70 deg. for which the control is set, according to Mr. Scott.

## *New Relay Schemes and Illumination*

Relays and their operation formed the major subject treated in the technical session held Wednesday afternoon, at which N. W. Storer presided. The papers presented gave examples of recent relay practices, and a remarkable unanimity of opinion existed on the relay methods best suited for different systems.

The Duquesne Light Company has recently installed a new relay system on the 66-kv. ring surrounding Pittsburgh. H. P. Sleeper described the method of relaying employed and the results of tests made on the installation. The ring is made of parallel lines and is sectionalized at seven points, two of which are generating stations. The greater part of the load is industrial-motor and synchronous converters. A number of relay schemes were investigated, and a scheme using balanced directional relays for short-circuit protection and selective differential current relays for ground protection was chosen.

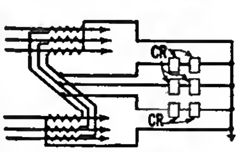
The short-circuit relays are of the CR type and the ground relays are rated at ⅓ amp. Interlocking relays are installed in the trip circuits of both lines to render the good line non-automatic for a few seconds after the relays have tripped out at one end of the defective line. This locks out the trip circuit of the good line until the relays at the opposite end of the section have had time to clear the line in trouble. On standard sections these relays are set at 0.4 second definite time. One 63-ohm, grounding resistor is used at each generating station, and the ground relays close contacts in 0.3 second. If the



CONNECTIONS OF BALANCE SCHEME USED (SLEEPER)

**SCHEME NO. 1**
Balanced Reverse Power Protection Only

Schematic Connections

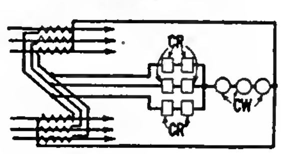


ADVANTAGES
1. Simplicity of wiring and equipment.
2. Directional single-line protection afforded.
3. No additional relays required for ground protection.
4. Requires dead grounded neutral.

DISADVANTAGES
1. Imposes severe voltage unbalance on line which will effect synchronous machines.
2. Severe damage may result as heavy ground current must pass to operate relays.

**SCHEME NO. 2**
Balanced Reverse Power Protection for Short Circuits and Watt Relay Protection for Grounds

Schematic Connections

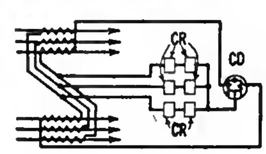


ADVANTAGES
1. Satisfied all conditions for short-circuit protection for both parallel and single-line operation.
2. Small ground current may be used which ensures the elimination of voltage disturbances.

DISADVANTAGES
1. Additional relays necessary for ground protection, at least one per circuit being required.
2. Wiring is complicated.
3. Extra grounding potential transformer required for one scheme using the watt ground relay.
4. Another scheme used three double contacting watt relays per pair of lines but this scheme does not have a dependable selectivity.

**SCHEME NO. 3**
Balanced Reverse Power Protection for Short Circuits and Balanced Current Relay Protection for Grounds

Schematic Connections

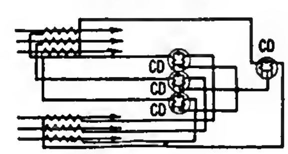


ADVANTAGES
1. Wiring and equipment simple, only one set of relays being required for ground protection of two parallel lines.
2. Satisfies all short-circuit conditions for both parallel and single-line operation.
3. Small ground current required to operate ground relays.
4. Ground relays very positive in action.

DISADVANTAGES
1. Ground protection is inoperative when ring is open.
2. Ground relays are non-directional for single-line operation.

**SCHEME NO. 4**
Balanced Current Relays for both Short Circuit and Ground Faults

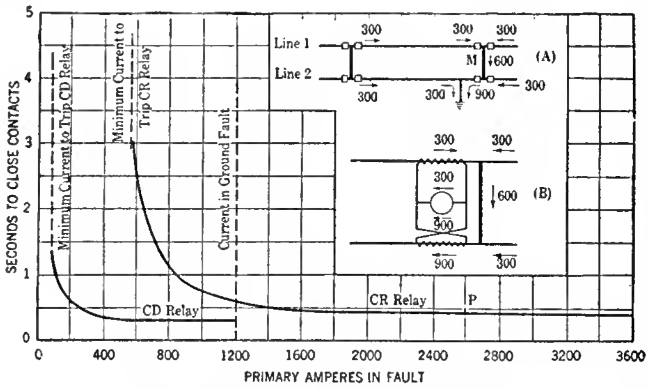
Schematic Connections



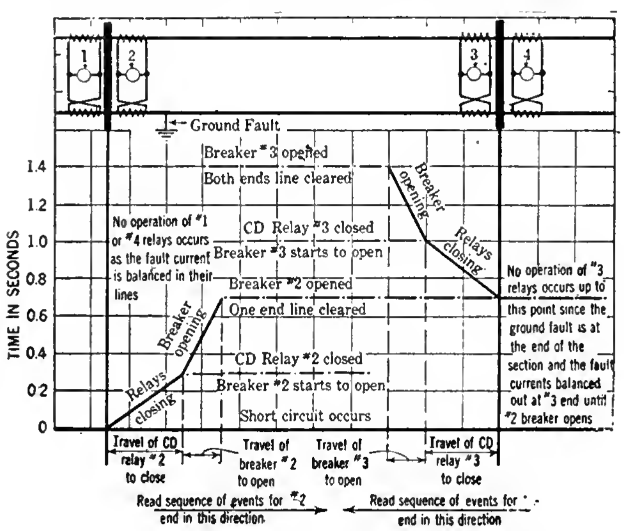
ADVANTAGES
1. Simple wiring and equipment.
2. Only one ground relay required for ground protection of two parallel lines.
3. No potential connections required.
4. Ground relays very positive in action.

DISADVANTAGES
1. Neither short circuit nor ground protection is operative if ring is open.
2. Single-line operation is not directionally selective.

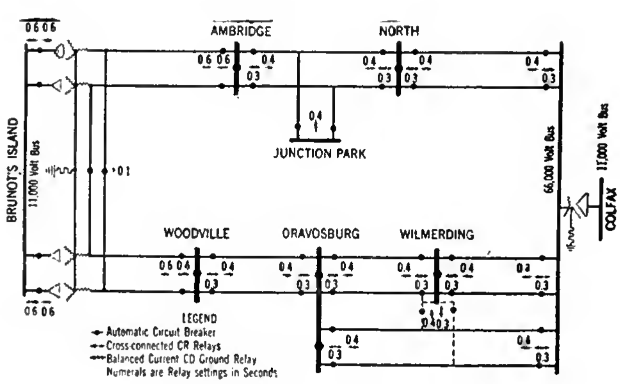
SEVERAL BALANCE SCHEMES WERE COMPARED AND NO. 3 CHOSEN (SLEEPER)



SETTINGS FOR SHORT-CIRCUIT AND GROUND RELAYS (SLEEPER)



TIME CURVES OF RELAY PERFORMANCE (SLEEPER)

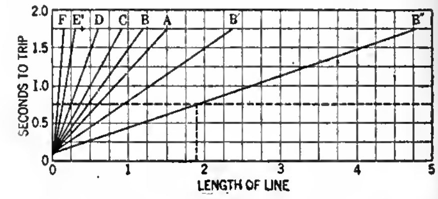


SYSTEM RELAY LAYOUT AND SETTINGS (SLEEPER)

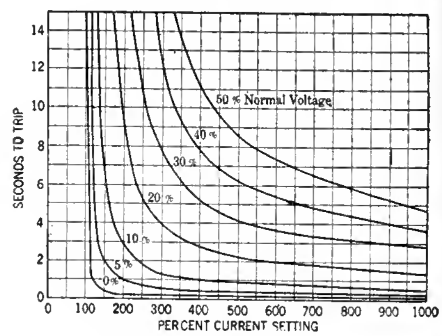
ground relays fail to respond to the ground fault, the grounding resistors are short-circuited after a period of ten seconds. This places a dead ground on the system and puts the short-circuit current in the CD relays, which causes them to operate.

A series of dead grounds were put on the ring to test the relaying. The dead ground was then replaced by a resistance ground, and that in turn by an arcing ground. A total of twenty-eight grounds was put on the system without damage, and the resultant relay operation was satisfactory.

A new device for accurately isolating trouble was described in a paper entitled "The Distance Relay for Automatically Sectionalizing Electrical Network," by Leslie N. Crichton. In determining the distance the relay makes use of the balance principle and bases its calculations upon the value of current and voltage existing at the time of the short circuit. In principle the relay has a current coil arranged to close contacts, while a voltage coil is so arranged that as long as voltage is applied it will tend to overpower the current coil and prevent the contacts from closing. The two coils are adjusted so that on a section of line the current coil will just overpower the voltage coil when a short circuit occurs at the far end of the section. The relay is so designed that when the trouble is close it will operate instantaneously, but when the trouble is some distance away it will operate slowly, so as to allow any relay which is nearer to the trouble to act. The induction-type relay has a disk which is rotated by the current coil whenever the current reaches sufficient magnitude, the movement of the disk being damped by the permanent magnet so that its speed is proportional to the current. The movement of this disk does not directly close the contacts, but instead it tightens a spiral spring. On the other end of this spring is fastened a lever which is pivoted at the center and which has the contacts on one end and the core of the voltage coil on the other. This voltage coil is so arranged that it opposes the closing of the contacts. When in the neutral position all parts of the relay are balanced, so that if there is no voltage on the voltage coil a very slight movement of the disk will close the contacts. Similarly, if the voltage is applied to the restraining coil, its unbalance will prevent the contacts from being closed until the spring has been tightened up sufficiently to overcome this, and since the motion of the disk is damped, this will require some time. The voltage coil will discriminate quite positively between zero voltage and 5 per cent of normal voltage. In addition to the distance-determining element, the relay has a directional element in order to locate definitely the direction of the trouble as well as its distance away. The directional contacts are in series with the distance contacts and act as a sort of check valve to prevent the relay from operating when power is flowing toward the busbars. The author claims for the relay that all dead short circuit will be cleared within one second and the majority of them in considerably less time, and trouble will be cleared with equal rapidity from all parts of the system. In effect, the well-known directional time-element overcurrent relay has been taken and sufficient "brains" given it to enable it to determine what time limit it should have in its particular location.

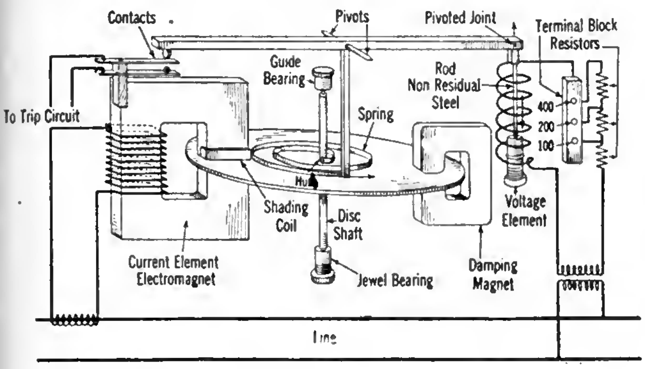


TIME-DISTANCE CURVE FOR THE DISTANCE RELAY (CRICHTON)



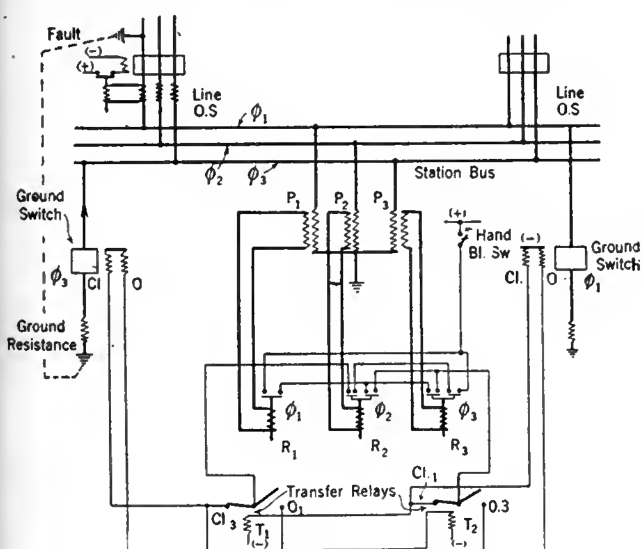
TIME-CURRENT CURVES AT VARIOUS VOLTAGES (CRICHTON)

In the opinion of P. Ackerman, who contributed a paper on "A Ground-Selector Relay Scheme," the adoption of a recently devised scheme of protection of the ground-selector type makes it possible for the ungrounded system of transmission to have all the advantages of the grounded system and some in addition. Operating results were given in the paper which, the author held, show conclusively that the ground selector



ELEMENTARY DIAGRAM OF DISTANCE RELAY WITH DIRECTIONAL ELEMENT (CRICHTON)

will bring the ungrounded system to the same state of perfection that is claimed for the grounded system without having to resort to artificial grounding methods; also that the ground selector prevents permanent secondary breakdowns and permits clearance of grounds and line trouble as effectively as the grounded system and retains besides the advantage of less numerous voltage disturbances and partial interruptions and the flexibility of permissible transformer connections. The author said that the ungrounded system, combined with ground selectors and equipped with an effective relay protection, should therefore prove advantageous com-



CONNECTIONS OF GROUND SELECTOR RELAY (ACKERMAN)

pared with the grounded system, at least as far as distributing systems are concerned and for voltages not exceeding 60,000.

The fundamental idea of the ground selector is, he pointed out, to produce intentionally a short circuit immediately after a ground develops on the system. This is accomplished by automatically grounding one of the sound phases at the main station bus by closing an oil switch immediately upon the occurrence of a ground. Thus a complete phase to phase short circuit is produced, and as a result overload current will flow into the faulty line as if the line were on short circuit. Accordingly the ordinary overload protection will enter into action and disconnect the faulty line. As soon as the trouble has cleared itself the ground switch will open automatically and thus restore the system to normal condition. Various other features had to be embodied to make the device practical, but no great difficulty was found in developing the scheme and installing it on two systems in Canada.

Operating records over a period of time were given in detail in the paper to show the efficiency of the device for the purposes intended. The author made rigid analyses and comparisons of the ungrounded and grounded systems based upon the use of the selector scheme.

### DISCUSSION SHOWS THAT PROGRESS HAS BEEN MADE IN RELAYING

R. N. Conwell suggested that many relay tests could be avoided and system operations improved if accurate records were kept of all relay operations. He also pointed out that the relay scheme developed by Mr. Ackerman was a modification of the arc suppressor and limited in its application because of complexity and cost. In his opinion, the newer relays described offered opportunity for greater developments in relay practice.

It was the opinion of P. Ackerman that an instantaneous relay placed in series with a definite time relay and connected on the balanced principle would give results similar to those derived from the relay described by Mr. Crichton. Mr. Ackerman thought great possibilities were opened by using the Crichton relay for certain applications.

W. V. Lovell stated that he could not find data to support the conclusions in the Ackerman paper to the effect that greater opportunity was offered for inductive interference under abnormal operations if the grounded neutral were used than under the scheme proposed by Mr. Ackerman.

L. P. Ferris stated that the amount of resistance in the grounded neutral will affect the amount of inductive interference appreciably and that the relative location of communication and power circuits would be a vital factor in considering the interference action if the schemes proposed by Mr. Ackerman were used.

E. A. Hester announced that a handbook on relays and protective schemes would be published in the fall under the auspices of the A. I. E. E. and N. E. L. A.

A voltage-restraining relay scheme was used for several years on the West Penn system, H. H. Langstaff stated, and gave good service in the original installation. Later this system was discontinued on account of the purchase of properties equipped with other relay schemes and because it is essential that relay applications be made quickly on every installation. He said that when using balanced protection it was essential to have a high setting to maintain the remaining line in service when one of two parallel lines is tripped on account of trouble. He also observed that it was often difficult to determine whether the ground relay or the overload relay tripped the circuit when trouble occurred. He advocated testing all relays in the laboratory before installation and said that the West Penn company had used twenty installations of 12-volt storage batteries with trickling chargers for control power and had experienced only one failure in two years.

C. M. Moss pointed out that one objection to the installation of balanced-relay schemes was the amount of control wiring and number of cross-connections required.

An interesting example of high-grade illuminating engineering design and practice was presented in a paper by F. A. Mott and L. A. Jones which described the installation for the Eastman Theater and School of Music at Rochester, N. Y. A great many experimental analyses were made previous to the installation to determine the limits for illumination and brightness. The problem was to get illumination without too much brightness so that the usual contrast between darkness and brightness in motion-picture theaters would be eliminated. At the same time, no loss of quality was desired in the pictures.

A successful solution was obtained and a detailed description was given in the paper of the equipment, controls and intensities used. Standard fixtures with ornamentation were largely used.

## *Reactors, Lightning Disturbance and Insulators*

The importance of low ground resistance in lightning-arrester installations and the current value to consider in designing and installing reactors were the chief subjects of discussion at the Thursday morning session.

A very elaborate investigation was made by Malcolm MacLaren, professor of electrical engineering at Princeton University, of the system of the Philadelphia Electric Company with regard to lightning disturbances on the low-tension distribution lines. The main primary distribution system has 2,300 volts and the high-tension system 13,200 volts. The lightning troubles on the low-tension system are of comparatively infrequent occurrence, the author reported in his paper, "Survey of Lightning Disturbances on a Distribution System," and much less serious in character than on the other parts of the system. The number of fuses blown in the houses was no indication of the effect of lightning, because of the large number blown by other causes. The number of injuries to house fixtures never reached 150 per month, and these injuries were irregularly distributed. There was, however, distinct evidence that a majority of the meter burn-outs were due to lightning as there was a large increase in the number of failures during the summer months. All the evidence pointed to the fact that the lightning disturbances in the secondary circuits are not transmitted from the primaries to the transformers, but originated in the secondaries themselves and are controlled largely by the length of these circuits. The losses occur indiscriminately upon meters connected to ungrounded circuits or circuits grounded outside the premises or directly at the meters. No true perspective upon the protective value of these methods of connection was obtained, however, as the relative number of meters using each type of connection was not known.

Experience with more than 230 current-limiting reactors of five different types of construction indicated to the Public Service Electric Company of New Jersey, according to the paper of N. L. Pollard, that most of the troubles to which they give rise can be attributed to poor mechanical construction and especially to insufficient consideration of thermal capacity. As a result of the experience gained on the New Jersey system greatly improved designs of reactors are now available.

Some facts regarding these reactors and the performance they have given are shown in the table reproduced. While the number of instances in which these reactors functioned properly far exceeded the number of failures, it is in the causes of failures and the methods of overcoming them that the most valuable information lies. Only two cases of trouble developed in the type A reactors in ten years (see page 1031). The first was caused by water grounding one of the coils, and the second was caused by shrinkage of the wooden strips supporting the coils, thus allowing the windings to become slack and eventually short-circuited.

Numerous cases of short circuits and complete wreckage of type B coils indicated that they were not sufficiently braced and did not have sufficient clearance between layers and between coils and metal tie rods to withstand the severe operating conditions. In most cases failure occurred between the outer turn of either the top or bottom coil and one of the brass tie rods. Of the twenty-four failures experienced, two were due to short-circuiting of turns, six to arcing from top to bottom, three from lugs burning off, two from windings burning open and eleven were complete failures. This design was discontinued and an improved one developed giving greater space between layers, wood tie rods instead of brass, heavier supports, insulators of higher flashover, and terminals brought out one on top and one on bottom.

Only two failures were experienced with type C coils. The first occurred after two years of service, when one of the coils arced from top to bottom; the second oc-

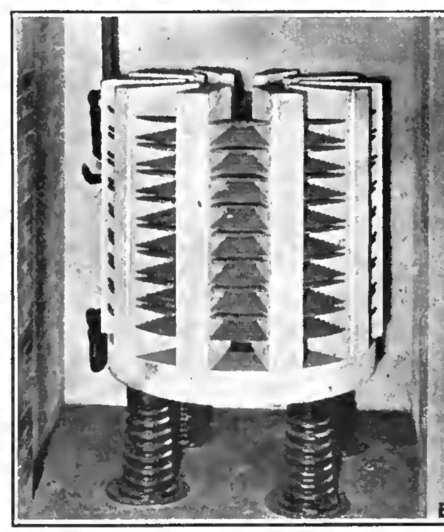
FIVE TYPES OF REACTORS WITH WHICH THE NEW JERSEY COMPANY HAS HAD EXPERIENCE (POLLARD)

Type A—Earliest type of reactor installed. Type B—Coils are made of stranded conductors wound in parallel layers with notched strips and specially prepared molded non-inflammable material between layers. Non-magnetic castings are placed at the top and bottom of the coils, and the different sections are held together by brass tie rods. All the terminals are at the top of the reactor. Type C—Series-wound, similar to type B except that insulated cable is used. The axis is vertical and the coils are partly inclosed by porcelain bricks with soapstone slabs at the top and bottom, held together by brass tie rods. Type D—These coils have two sections in series, each being made up of six pancake coils in parallel. One section has a diameter approximately 3 in. less than the other. The coils have a horizontal axis and are partly inclosed with porcelain bricks. Type E—In later units of this type the concrete supports are closer together.



curred when several turns short-circuited in another coil after three years of service. Both coils were repaired and neither has given any further trouble.

Within three months after the installation of type D reactors three total failures occurred. In each case the coil caught fire from arcing between a number of turns, and before the fire could be extinguished the coils were badly burned, loosened, distorted and partly wrecked. All of the coils were on two separate occasions returned to the manufacturer for rebuilding and reinforcing without successful results. Furthermore, attempts of the New Jersey company to rebuild them were ineffective in making them strong enough to withstand short-circuit conditions. At present whenever one of these coils becomes noisy it is taken out of service and scrapped.

About one year after the first installation of type E reactors there were two instances of trouble: The first occurred on a tie feeder and resulted in the short-circuiting of two reactors; the second occurred on another tie feeder and caused the concrete to crack on one of the coils. These demonstrations were sufficient to prove that the concrete supports were not close enough to prevent the conductors from pulling together. These coils were returned to the factory and additional concrete supports placed half way between the old ones.

In conclusion, the author of the paper urged that lightning arresters be installed on the feeder side of reactors when they feed underground cable to relieve the system of strain during disturbances.

R. E. Doherty and F. H. Kierstead, in their paper on "Short-Circuit Forces on Reactor Supports," discussed and worked out in a theoretical way the character of the force which is required to hold a reactor as a whole against short-circuit forces. The mechanical stress in the supporting members of the reactor is, they found, determined by the dimensions and the magnitude of the resultant force, but under accelerated motion the reaction of the mass enters, and if the supporting members are resilient, then this enters into the situation as another factor in determining the mechanical stress produced by a given impressed force. The paper showed that if any motion be permitted in the reactor supports the mass and resiliency factor become active and the maximum stress may be increased to the order of 25 per cent. On the other hand, if the motion of the reactor is prevented by sufficient initial bolt tension, then the maximum stress need be only as great as that corresponding to the maximum instantaneous peak of the electromagnetic force. Where the reactor is not

held rigidly against the motion, the maximum force on the holding device depends in a decisive way upon the ratio of the frequency of natural oscillation to the electrical circuit frequency. If, however, the reactor is held rigidly, then the maximum force on the holding device will be independent of the frequency ratios and need be only slightly in excess of the peak magnetic force. If the reactor is not held rigidly and the natural oscillation frequency is large compared with the circuit frequency, the maximum force will occur in the first cycle and will usually be as great as or greater than the maximum magnetic force.

More analytical papers are needed to permit the solving of operating problems, declared C. E. Stone, who pointed out that the requirements for lightning arresters are conflicting. He said that the solution of line protection for 4,000-11,000-volt systems is far from solved.

Low ground resistance is absolutely imperative to good lightning arrester operation, declared K. B. MacEachron, who said that attempts of manufacturers to reduce arrester resistance would be of little avail if this was not provided. High ground resistance will either decrease discharge capacity or subject apparatus to severe voltage surges.

In referring to tests of the New York Edison Company with reactors W. B. Kirk suggested that double the sustained short-circuit-current peak value should be used in calculating reactor tests. However, J. F. Peters said that 2.8 times the sustained value is more appropriate. H. O. Stevens recommended the use of the peak value of the displaced wave.

The insulator sub-committee of the A. I. E. E. standards committee presented a report on standardized insulator tests. For pin insulators a dry flashover test is specified in detail by having the insulator mounted according to specification and voltage applied at a uniform rate of 5,000 volts per second until flashover occurs. The wet-test equipment is the same as for the dry test, and a 45-deg. spray is applied at the rate of 0.2 in. per minute. The water resistance is specified at from 3,000 ohms to 6,000 ohms per inch cube at a nozzle pressure of between 35 lb. and 50 lb. per square inch. A puncture test on the insulator immersed in oil specifies an applied voltage of not more than three-fourths the dry flashover voltage and raised at 5,000 volts per minute for insulators having an average puncture voltage of 200,000 or less and at double this rate for those having a higher puncture voltage. A corona test calls for the application of voltage in a darkened room until streamers occur and a slow lowering until brush discharges disappear. The point of disappearance is the corona voltage. A test for mechanical strength is specified while the insulator has a voltage applied 15 per cent less than the dry flashover value. The load is increased at the rate of 2,000 lb. per minute until puncture occurs.

For suspension-type insulators the dry flashover test calls for the application of voltage at 5,000 volts per second until flashover occurs. All other details must conform to A. I. E. E. standards. The details of the wet flashover tests are very similar to those for the pin-insulator tests, and the same can be said of the puncture test specified by the committee. Data have been tabulated from twenty-seven operating companies in reply to a questionnaire, and specific recommendations for factory tests have been added to the former report.

# February Sets Record

### Unusual Energy Requirements of Central-Station Customers Reported from Every Section of the Country—Two Records Established

REPORTS received by the ELECTRICAL WORLD for the month of February from central generating and distributing companies representing 72 per cent of the installed generator rating of the country indicate that two new records were established by the industry during the month.

The average daily output during February was 186,-239,000 kw.-hr., which exceeded the previous record, made

during January, by 8,000,000 kw.-hr. In addition, the average daily revenue from the sale of energy during the month was $3,917,000, which exceeded the former record, also made during January, by $137,000. This is the first instance in the recent history of the industry in which the operations during February have exceeded those of the previous December and January. The operations of the industry for the first two months of the year point unmistakably to one of the most prosperous years in the history of the central station.

Complete returns indicate that the total output of the central generating stations in the country for 1922 was 52,775,000,000 kw.-hr. The output in 1921 was 43,905,000,000 kw.-hr., indicating an increase over that year of industrial depression of 8,870,000,000 kw.-hr., or 20.1 per cent. The output in the past year was also 15.7 per cent over 1920, a year of great industrial activity.

The gross revenue from the sale of energy during 1922 was $1,084,000,000, indicating an increase of $139,640,000, or 14.9 per cent, over 1921. The total operating and maintenance expenses, exclusive of interest, taxes, depreciation or sinking funds, during 1922 were $481,570,000, against $432,400,000 in 1921 and $440,000,000 in 1920, a remarkable showing when the high cost of fuel is taken into consideration.

# Grading Utilities on Service

## Instructions Under Which Illinois Commerce Commission Inspectors Work in Drawing Up Their Classification—Technical, Business and Public Relations Factors Are All Taken Into Consideration

By J. HOWARD MATHEWS
*Service Engineer Illinois Commerce Commission*

"BY THEIR fruits shall ye know them" might be taken from its scriptural context and translated "By their service shall ye know them" for application to public utility activities. Given supervision over service as well as over other activities of the utilities, a public utility commission becomes the recipient of all sorts of complaints, some justified and many unjustified. For the purpose of bringing up the service averages of the utilities in the state, checking compliance with the service rules established by the commission, and above all forestalling as far as possible the complaints and controversies that do neither the utilities nor the public any good, the engineering section of the Illinois Commerce Commission has established a grading system under which Illinois utilities are being graded in the regular routine of inspection. Periodic reports are made, all the utilities in the state receiving copies of the grades assigned to the various localities. The first list was mailed on Aug. 10, 1922, to all electric utilities in the state, covering about seven hundred localities. The highest grade was 96.45 per cent and the lowest 56.5 per cent. Needless to say, the list attracted widespread interest. The reaction was favorable, only one organization expressing resentment, which was dispelled when the company became familiar with the detailed instructions under which the grading is done. The seriousness with which some of the utilities view the grading was shown recently when one of the larger companies desired emergency service from another large company. The latter was reluctant to furnish the service until assured by the service division of the commission that the poor voltage regulation, if any developed resulting from the abnormal load, would be overlooked in the grading.

TABLE I—TYPICAL GRADING OF AN ELECTRIC UTILITY AS SHOWN ON AN INSPECTOR'S REPORT

This form is used in grading service of electric utilities. Grades have been assumed for the various factors of service and computations made to determine the final grade.

| Condition of Service | Weight | Grade | Weighted Score |
|---|---|---|---|
| Continuity of service | 30 | 89 | 2,670 |
| Voltage regulation | 15 | 80 | 1,200 |
| Handling of complaints | 10 | 80 | 800 |
| Meter testing | 7 | 95 | 665 |
| Consumers' attitude | 5 | 80 | 400 |
| Provisions for emergency | 3 | 60 | 180 |
| Adequacy of capacity | 2 | 80 | 160 |
| Construction of distribution lines | 2 | 80 | 160 |
| Maintenance of distribution lines | 2 | 75 | 150 |
| Extension policy | 2 | 95 | 190 |
| Furnishing new service | 1 | 95 | 95 |
| Adjustment of bills | 1 | 100 | 100 |
| Billing | 1 | 90 | 90 |
| Grounding of secondaries | 1 | 60 | 60 |
| Total of service | 82 | ... | .... |
| Records: | | | |
| Record of interruptions | 5 | 60 | 300 |
| Voltage surveys and records | 5 | 20 | 100 |
| Records of meters and tests | 4 | 80 | 320 |
| Record of complaints | 4 | 0 | 000 |
| Total for records | 18 | ... | |
| Final grade, | | | 76.40 |

When any company is informed of the results of an inspection, a list showing the detailed grades given for each factor in service rating is also supplied. Some companies delegate individuals to visit the commission offices to study the grades in detail and learn how their standing may be improved, which means an improvement in service. Some have made an immediate study to remedy conditions that produced a low grading, and the engineering section of the commission has been asked in a number of cases to make another inspection so that the showing made would be better.

### Factors in Electric Utility Service

The most important factors entering into electric utility service are thirteen in number. They are: (1) Continuity of service, (2) voltage and frequency regulation, (3) accuracy of meter registration, (4) construction and maintenance, (5) adequacy of capacity, (6) provisions for emergency, (7) adjustment of bills, (8) billing, (9) extension policy, (10) promptness of furnishing new service, (11) handling of complaints, (12) courtesy of utility representatives, and (13) testing of service and keeping of records.

It is fairly obvious that such items as continuity of service, voltage regulation, meter accuracy, extension policies, handling of complaints and courtesy of utility representatives have a direct bearing on public relations. The others are perhaps not so direct in their relation but are of vital importance in maintaining the factors mentioned on a satisfactory basis.

Table I shows the various factors and the weight, typical grade and typical weighted score as well as the final grade recorded on an inspection sheet. Detailed instructions to inspectors have been prepared to insure uniformity of opinion and in so far as possible to eliminate the element of personal judgment.

These instructions are so specific that by their use any one would arrive at virtually the same final grade that a commission inspector would reach. It is apparent from a study of these instructions that the grading is not based on compliance with commission rules, but rather on service conditions and on records that any well-managed company would desire to keep. For this reason the operating companies could use these instructions to grade their own service, delegating some individual to study service conditions and to assign a grade on his knowledge obtained through inspections. Such a course would, in the opinion of the writer, be highly beneficial, and some of the most progressive utilities already have it under consideration.

The method as outlined in the inspectors' instructions for arriving at the values assigned to the various factors is as follows:

*Continuity of Service.*—Grades for continuity of service

depend upon the total duration of outages, number of interruptions per month and the time they occur. Table II shows grades to be given under different conditions. For the purpose of grading, the following classification of interruptions has been made, those falling in class A being least serious and those in class C most serious. Specifically, interruptions should be classified as follows:

**Class A**

1. Between 11 p.m. and morning.
2. When service is intentionally interrupted for the purpose of working on line, in stations, etc. (It is assumed that proper notice of such interruptions will be given consumers likely to be affected.)
3. During the daytime when the interruption does not come in class B or C.

**Class B**

(Usually applicable to power service in small and medium-size towns.)

Where interruptions affect power users having a combined connected load of 25 hp. or more, the use of such power being at least thirty hours per month. This class will usually include interruptions to grain elevators, mills, pumps, etc., operating short hours on indefinite schedules.

**Class C**

1. Between dusk and 11 p.m.
2. Interruptions in the daytime where they affect power used for industrial purposes, such as manufacturing and mining, where the service is usually used on a definite schedule of several hours daily and where the interruption may result in serious economic loss to the industries.

*Voltage Regulation.*—To determine the grade for voltage regulation during the lighting period the deductions given in Table III should be made. If the voltage is above the standard, or below the standard at other periods than during the lighting hours, the deduction from the grade shall be only one-third of that shown in the table.

*Handling of Complaints.*—Grading on this is to cover courtesy of employees, promptness and efficiency in disposing of complaints and success in satisfying complainants. To assist in determining the grade, the following apportionment of percentages is to be used:

| | Per Cent |
|---|---|
| 1. Efficiency and promptness of employees in eliminating condition complained of | 50 |
| 2. Courtesy and tact of employees | 30 |
| 3. Action of company to prevent recurrence of condition | 20 |
| Note.—If no records of complaints are kept, give no more than | 90 |

*Meter Testing.*—

| | Per Cent |
|---|---|
| (a) If initial tests are not made, deduct | 10 |
| (b) If installation tests are overdue (depending on per cent of tests and length of time overdue), deduct | 1 to 20 |
| (c) If periodic tests are overdue, deduct 1 to 4 per cent for each per cent of meters overdue in accordance with the following: | |
| If 1 to 6 months overdue, deduct | 1 |
| If 7 to 12 months overdue, deduct | 2 |
| If 13 to 18 months overdue, deduct | 3 |
| If 19 to 24 months overdue, deduct | 4 |
| (d) If proper testing facilities and equipment are not provided and checked (depending on seriousness of violation), deduct | 1 to 15 |
| (e) If testing is not done in accordance with standard practice, or where proper methods are not employed, deduct | 1 to 20 |
| (f) If request tests are not willingly and properly made, deduct | 10 |
| Note 1.—If initial tests only are made, allow not more than | 10 |
| If installation tests only are made, allow not more than | 20 |
| If periodic tests only are made, allow not more than | 70 |

Note 2.—Where installation meter tests or periodic meter tests are not yet overdue, but very nearly so, the grade given for meter testing should be determined by the judgment of the inspector and should depend upon the possibility or the likelihood that these tests will be completed within the required period in conformity with the rules.

*Consumers' Attitude.*—The following instructions serve as a guide in grading this particular factor of service:

| Class | Attitude | Grade | Instructions for Classification |
|---|---|---|---|
| A | Excellent | 95-100 | Practically everybody satisfied and commending company for its service. |
| B | Good | 85-95 | Where those interviewed have practically no complaint; neither do they have any particular commendation to make, showing a general spirit of indifference. |
| C | Fair | 70-85 | Some complaint. A general feeling that service is not quite what it ought to be. |
| D | Poor | 40-70 | Attitude generally unfavorable. A general criticism of service, but public tolerant. |
| E | Very unfavorable | 00-40 | Public critical and antagonistic with possible agitation for service from some other source. |

The grading is to cover the attitude toward the company, its employees and its service as this attitude has been developed through the furnishing of this particular class of service. Interviews should be held with at least two city

TABLE II—USED TO GRADE UTILITIES FOR CONTINUITY OF ELECTRIC SERVICE

| Hours of Interruptions per Month | | | Number of Interruptions per Month (Including Kick-offs) | | | | | |
|---|---|---|---|---|---|---|---|---|
| Class A | Class B | Class C | 0–8 | 9–16 | 17–24 | 25–32 | 33–40 | 41–50 |
| 0 | 0 | 0 | 100 | 98 | 96 | 94 | 92 | 90 |
| 0 35 | 0.25 | 0.20 | 99 | 97 | 95 | 93 | 91 | 89 |
| 0 70 | 0.50 | 0.40 | 98 | 96 | 94 | 92 | 90 | 88 |
| 1 00 | 0.75 | 0.60 | 97 | 95 | 93 | 91 | 89 | 87 |
| 1 50 | 1.00 | 0.80 | 96 | 94 | 92 | 90 | 88 | 86 |
| 2 00 | 1.40 | 1.00 | 95 | 93 | 91 | 89 | 87 | 85 |
| 2 50 | 1.60 | 1.25 | 94 | 92 | 90 | 88 | 86 | 84 |
| 3.00 | 2.00 | 1.50 | 93 | 91 | 89 | 87 | 85 | 83 |

| 83.00 | 78.00 | 66.00 | 22 | 20 | 18 | 16 | 14 | 12 |
| 87.50 | 81.00 | 69.00 | 21 | 19 | 17 | 15 | 13 | 11 |
| 90.00 | 84.00 | 72.00 | 20 | 18 | 16 | 14 | 12 | 10 |
| ..... | 87.00 | 75.00 | 19 | 17 | 15 | 13 | 11 | 9 |
| ..... | 90.00 | 78.00 | 18 | 16 | 14 | 12 | 10 | 8 |

*Use of Table*—Column A will be used when two-thirds or more of the total time of outages is in class A.

Column B will be used when most of the total time of outages occurs in class B or when about one-half of the total time falls in class A and one-half in class C.

Column C will be used when two-thirds or more of the total time of outages falls in class C. In certain cases interpolation between the curves is recommended. For instance, if 10 per cent should fall in class A, 45 per cent in class B, 45 per cent in class C, a compromise between the results secured from curves B and C should be used.

The table is based on interruptions per month covering the nine months' period previous to the inspection or the period since the last inspection. The object in using a nine months' period is to insure that part of the period will cover the months where transmission and distribution systems are usually affected by storms; also to insure the covering of certain months not usually affected by storms

In the case of partial interruptions, multiply the duration of interruptions by the per cent of the consumers affected and consider the resultant time as a total interruption to the entire community. To illustrate: An interruption of five hours to 20 per cent of the consumers should be considered equivalent to one hour's total interruption. Interruptions to street-lighting circuits shall be counted in determining the number of interruptions per month, but their duration shall not be considered in determining hours of interruptions.

officials if possible, representatives of civic organizations, representative business men and representative consumers. If it appears necessary to give a very low grade, greater care should be taken to determine accurately the public attitude.

*Provisions for Emergency.*—In grading provisions for emergency make the following deductions:

1. Subtract 5 per cent for each hour of interruption per month (counting only those interruptions of thirty minutes or more duration).
2. In addition to deductions for interruptions outlined under (1), make the following deductions:

| | Per Cent |
|---|---|
| (a) Two transmission lines and standby plant under steam, deduct | 0 to 10 |
| (b) One transmission line or local generating plant with reserve steam plant under steam, deduct | 0 to 15 |
| (c) Two transmission lines on different pole lines, deduct | 5 to 15 |
| (d) Two transmission lines on same pole line, deduct | 10 to 20 |
| (e) One transmission line reserve steam plant not under steam, deduct | 10 to 25 |
| (f) One transmission line—no reserve supply. Local generating plant—no reserve, deduct | 15 to 40 |

Whether the minimum or maximum deduction is made under the above rule will depend on the following:

(a)* Dependability of source of supply (including construction and maintenance of plant, transmission line and substation).
(b) Reserve plant equipment, transformers, etc.
(c) Availability of workmen in emergency at point of trouble, consideration being given to distance to be traveled, kinds of roads, transportation, etc.
(d) Lightning arrester equipment.

*Note.—This is the only place where consideration is given to construction and maintenance of supply sources. It may seem at first glance that any deduction where standby equipment is maintained is not exactly logical but the grade assigned will depend on the protection given; viz., it might be nearly 100 per cent where the standby equipment is so located that the likelihood of service interruptions is almost nil. In less favorable situations the grade would be lower.

*Adequacy of Capacity.*—The following table gives the possible deductions for inadequacy of facilities:

| When served entirely from local plant: | Per Cent |
|---|---|
| Generator capacity | 25 |
| Boiler capacity | 20 |
| Prime-mover capacity | 20 |
| Auxiliaries, wiring, piping, switchboards | 10 |
| Distribution system (including transformers, primaries and secondaries) | 25 |
| **When served entirely or in part from transmission line:** | |
| Source of supply capacity (including generating plant) | 45 |
| Substation capacity | 30 |
| Distribution system (including transformers, primaries and secondaries) | 25 |

*Construction of Distribution Lines.*—The following table gives the possible deductions for poor construction:

| Material: | Per Cent |
|---|---|
| Poles—kind, size, quality, treatment | 35 |
| Wires | 10 |
| Arms, pins, braces, insulators | 10 |
| Guys—kind and size of anchors and wire | 5 |

| Workmanship: | Per Cent |
|---|---|
| Pole setting (including regularity of spacing) | 20 |
| Wire installation (sags, ties, splices) | 10 |
| Cross-arm assembly (including insulators, pins, braces and double arms) | 5 |
| Guying | 5 |

*Maintenance of Distribution Lines.*—The following table gives the possible deductions for poor maintenance:

| | Per Cent |
|---|---|
| Poles | 30 |
| Arms, pins, insulators, braces | 25 |
| Clearance from trees and structures | 20 |
| Clearance from other wires and from ground | 15 |
| Transformers | 5 |
| Lightning arresters | 5 |

*Extension Policy.*—Grade to depend on degree of compliance with rule covering line extensions and on promptness in making extensions.

*Furnishing New Service.*—Grade to depend on promptness in furnishing new service where line extensions are not necessary.

*Adjustment of Bills.*—Grade to be based on company's policy of refunding on over-registering meters.

*Billing.*—Grade to depend on whether bills are sent, whether they are properly, accurately and completely made out, whether suitable form is used, and whether billing is in any other way unsatisfactory.

*Grounding of Secondaries.*—

| | Per Cent |
|---|---|
| 1. For each per cent up to 20 of transformers not grounded, deduct | 2.0 |
| For each per cent above 20, deduct | 0.75 |
| 2. If grounds are not properly installed, multiply grade arrived at under (1) by 0.5 to 1.0. | |

# Letters from Our Readers

**A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute**

## Safety Should Not Wait on the Printer

*To the Editors of the* ELECTRICAL WORLD:

I desire to answer the recent letter by Dana Pierce of the Underwriters' Laboratories and of the code committee in regard to the new code, since to my mind it either gives a wrong impression or indicates a very serious situation.

Mr. Pierce's letter seems to imply that, in spite of the action of the code committee in regard to changes in practice, these changes are not to be recognized until they shall have been printed and issued in some special or regular form. Does this mean that the insurance companies are not going to recognize the changes and that they intend for a time to charge the extra premiums called for by their schedules for installations that are made in violation of the 1920 code but in accordance with the recent action of the code committee? Legally an insurance company has the right to charge any premium it chooses, but I cannot believe that the insurance companies really mean to do this. I believe Mr. Pierce's letter gives the wrong impression and that the insurance companies, rather than charging extra premiums for installations made in accordance with the changes, will welcome the changes.

In the case of municipal inspection the case is somewhat different. The right of a municipal inspector to dictate the details of electric installation rests on the police power of the state to secure safety for the public. Under our constitution a municipal inspector may not do anything he chooses but must act in accordance with the law. He may reject an installation or prevent connection to it because he considers it unsafe, but may not do so to satisfy his personal prejudices.

If a municipal inspector undertakes to use his office and his power improperly, the courts have the power and right to order him to do otherwise. The municipal inspectors are not bound by any particular edition of the code, nor in fact are they bound by the code or any code.

As Mr. Pierce indicates in his letter, each inspection department has the power and right to decide for itself just when (if ever) it will adopt the changes. It has the power to adopt them when the new code is issued or at some later date. It also has the power and right to adopt them at any time, as immediately. This is fully within the right of the inspection departments, and properly so, since it is their duty to work at all times for the best construction. They are not required to wait for the printer.

A code that is revised only at periodic intervals will obviously not include the better methods that have been developed since its last revision; hence an inspection department that is working for the best construction would seem most certainly to have not only the power and right but the duty to be ahead of the last printed code. Mr. Pierce's letter, however, seems to suggest that the inspectors should for several months adopt a different policy and that they should forbid certain forms of construction, not because they are unsafe but merely because a certain book has not been printed.

If a case comes before the court, the inspector cannot testify that he rejects an installation that is safe merely because the new code has not been printed, or rather, if he should so testify, the judge will order him to approve the installation and issue the permits. In order to maintain his position, the inspector will have to testify that in his honest opinion the installation is really unsafe. Now, in regard to the changes under discussion, there may be inspectors who will honestly so testify, but the great majority of our inspectors are both honest and able, and when the situation arises will undoubtedly allow the new methods without waiting for the printing of the changes in a particular form.

We all of us realize the importance of standard rules. In many cases the advantage of such rules is sufficiently great to warrant slight departures from the best practice. The importance and advantage of standard rules is, however, by no means controlling in all cases. Some changes are best brought about gradually.

I wish to suggest the following procedure: That inspection departments should continue to allow con-

struction according to the 1920 code until the new code is printed and distributed, and also allow it for such further time as in their judgment will reasonably permit manufacturer and wiring contractor to adjust themselves to the new conditions.

That in addition the inspection departments should allow construction according to the proposed changes and also according to any other improved methods which in their opinion will result safely so far as either fire or life or other similar hazard is concerned.

That such departure from the 1920 code should in all cases be made under special inspection such that the records of any unusual happening shall be available.

There would seem to be no question that most inspection departments have the power and right to follow the above procedure, the only exception that I think of being the cases where there is a state or municipal ordinance specifying the methods of construction.

If inspection departments will continue to allow the 1920 code for a reasonable time and will also as soon as practicable allow, as alternatives and under special inspection, the better methods recently acted on by the code committee, then I believe the best results will be obtained for the public. R. S. HALE.

### Some Hints About Rural Service

*To the Editors of the* ELECTRICAL WORLD:

I should like to offer a few comments in answer to your question which appeared in the ELECTRICAL WORLD for March 17: "How shall our farms be served with electricity?"

We are serving approximately seven hundred farms in the north central part of Ohio, as well as ten small towns having no greater population than four hundred people. The lines constructed and in operation pass probably a thousand more farms, which will give our lines seventeen hundred farm meters when development is completed. This, we estimate, will be in five years. Our average customer's light bill is $3 per month, at $1 service charge and 12 cents per kilowatt-hour consumption charge, with a discount of 10 per cent on bills of more than $5 per month. The billing fluctuates considerably throughout the year, but not so much as some "rural authorities" believe.

Our construction is all overhead, with the exception of four miles of underground line which we have placed for experimental purposes with the thought in mind that eventually (probably in twenty-five years), after the farm business is thoroughly developed, all farm circuits will be under ground. This condition will be brought about by legislation due to public opinion, which will be worked up about that time against all cheap overhead construction. Some people might ask: "Why not put these circuits under ground at the start?" This would be impossible economically. It will take twenty-five years to develop the use of electricity for power even after all the farms are connected to the lines.

My conclusions during the short period that we have been engaged in this rural business can be summed up as follows in some rules for the central-station man:

Don't plan a line that is capable of taking care of large power requirements, because the energy cannot be sold at this time.

Don't make an agreement to use farmers to do the labor on such lines. Build all lines with your own organization.

Never change your proposal after it is once submitted unless the change is for the benefit of the farmer.

Don't make any investment of company funds in the line. Each and every farmer can well afford to spend as an initial investment $800 for line, transformer, house wiring and meter. If he says he is unable and he has the acreage, he is not sufficiently "sold" on the idea of electricity.

Don't construct lines of more than 4,600 volts or less than No. 6 copper. Don't build three-phase lines; single-phase is sufficient for many years.

Wherever possible tie your lines together, using disconnecting switches at these tie-ins. This assures maximum service and capacity with few interruptions.

Don't be alarmed at rumors from your territory before the current is turned on. We find that if there is any delay through waiting for material the farmers get worried and will listen to almost anything unfavorable, even to the extent of thinking the whole project fraudulent; but, however impatient they become, just as soon as the current is turned on they will be your friends.

Use the card system for reading your meters, having the customer mark his meter reading.

Examine the transformer, meter and lightning arresters every six months at the company's expense.

Send out a circular letter every two months stressing the point that larger consumption of energy will mean cheaper rates and better service. Advertise on your meter cards.

In closing, let me inform manufacturers and central-station men, as well as contractors or persons interested in rural development, socially or economically, that the solution of the problem does not rest with the National Electric Light Association, or the Farm Bureau, or any other agency, but with the farmer as an individual and with the central-station man who will advocate and work for the things that will make rural development easier, such as immigration and small farms. Rural service can be made profitable. J. M. HEPP,

Mead Utilities Service Company, Shelby, Ohio. Rural Division.

### Proper Connections for Meter-Test Set

*To the Editors of the* ELECTRICAL WORLD:

I note in the issue of the ELECTRICAL WORLD for March 17 a description of a meter-test set by H. S. Edwards of the Kentucky Utility Company, Pineville, Ky. The connections which Mr. Edwards shows will produce a considerable error in his results in that the meter under test will record the losses in his rotating standard. The effect of this will be that he will set his meters slower than they should be with correct connections, thus incurring a loss of income on every meter. Mr. Edwards should extend his potential wires from his rotating standard so that he can supply them with current from the service side of the meter. This can easily be done with snap connectors which may be attached to the service switch. LEON C. WHITE,

Twin State Gas & Electric Company, Bennington Division, Bennington, Vt. Manager.

### A Correction

In the article entitled "Design of Alternating-Current Substation," by R. A. Hentz, in the issue of March 3, page 513, owing to editorial errors the drawings contain the words "wrought iron" instead of "weight" when applied to the compartments and transformers in the substations.

## Graphical Chart for Line Problems

**Charts Furnish a Convenient Means for Obtaining Voltage Drop in Distribution Layout Work—No Calculations Are Necessary When Using Charts**

IN DISTRIBUTION layout work it is desirable to know the line drop in advance, and yet it is inconvenient to have to perform the usual routine calculations, especially when many problems are handled each day. The charts described in this article were devised as a means of arriving at an accurate solution of line-drop problems quickly and without having to make any calculations whatever. In this respect they have proved very convenient to use in secondary and rural primary distribution layout work. They are flexible in so far as load, distance and power factor are concerned, but can be used only for the one voltage for which they are designed. However, this is not a serious obstacle as two charts would be sufficient for most companies, one for primary and one for secondary voltage.

The charts are based directly upon the solution of line drop by means of the vector diagram (Fig. 2):

Let $E_1$ = load voltage (assumed constant),

$\theta$ = angle of lag (or lead) of current at load,

$\phi$ = "wire angle" = arc tan $X/R$ and varies with the size and spacing of wires. The spacing is assumed to be constant for each chart, as usually standard construction will specify a certain spacing for each voltage class.

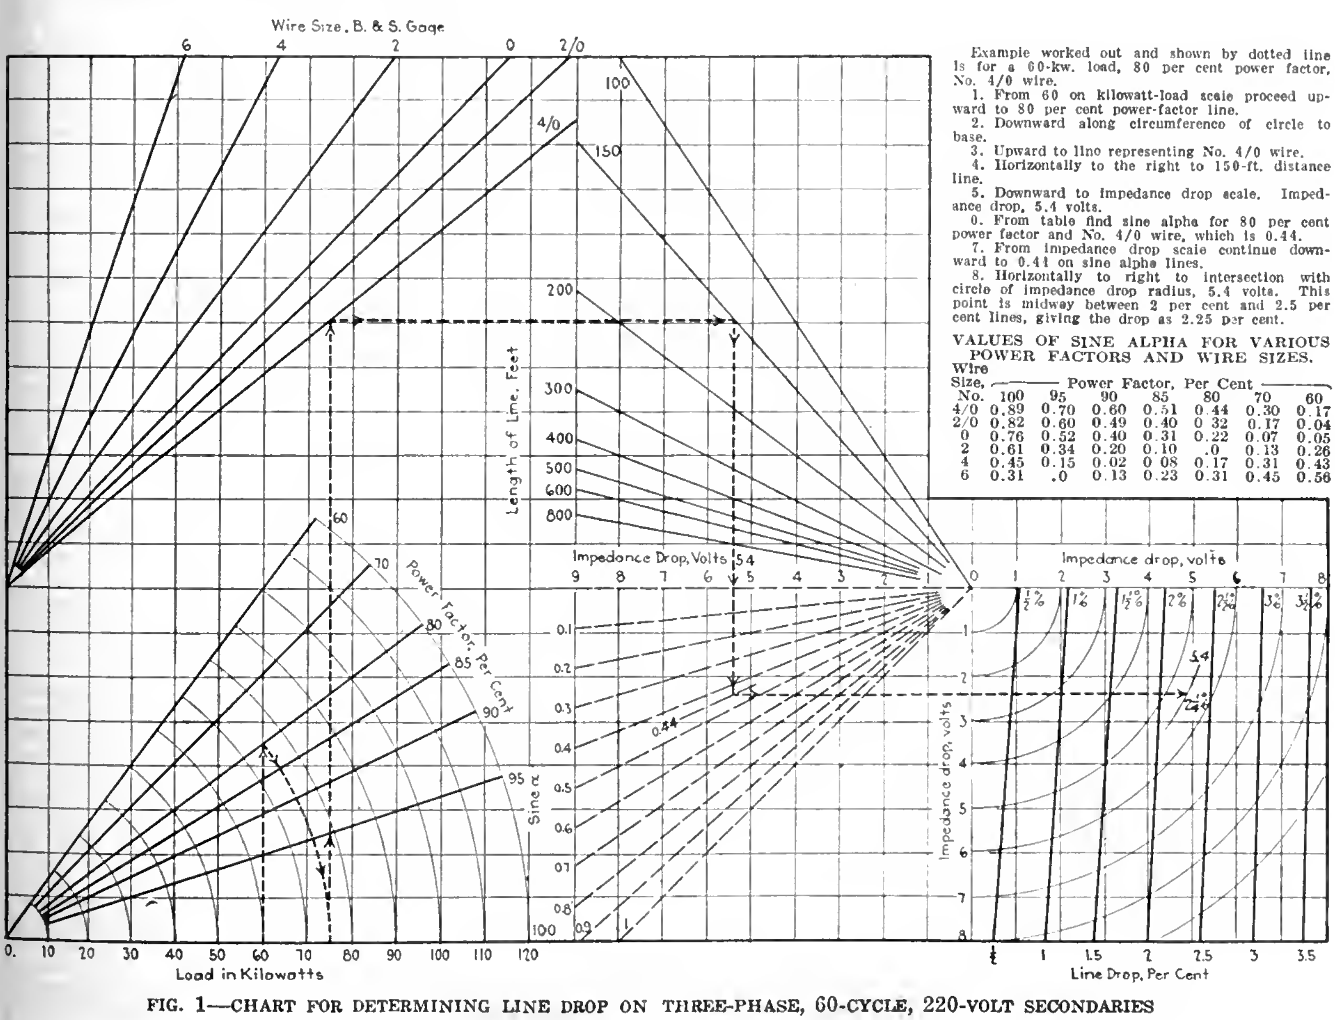
$E_g$ = voltage at source,

$E_d$ = impedance drop,

$E_g - E_1$ = line drop,

$HDI$ = locus of the impedance drop vector where the magnitude of the vector remains constant, but where the power factor or wire size (or spacing) varies (i.e., where $E_d$ remains constant in length and $\theta$ or $\phi$ vary);

$BE$ = locus of impedance drop where the value of the drop varies, but for a constant value of $\theta$ and $\phi$ (i.e., when the power factor, wire size and spacing remain constant, the impedance drop vector will be displaced from $E_1$ by the angle $\alpha$,



Example worked out and shown by dotted line is for a 60-kw. load, 80 per cent power factor, No. 4/0 wire.

1. From 60 on kilowatt-load scale proceed upward to 80 per cent power-factor line.
2. Downward along circumference of circle to base.
3. Upward to line representing No. 4/0 wire.
4. Horizontally to the right to 150-ft. distance line.
5. Downward to impedance drop scale. Impedance drop, 5.4 volts.
6. From table find sine alpha for 80 per cent power factor and No. 4/0 wire, which is 0.44.
7. From impedance drop scale continue downward to 0.44 on sine alpha lines.
8. Horizontally to right to intersection with circle of impedance drop radius, 5.4 volts. This point is midway between 2 per cent and 2.5 per cent lines, giving the drop as 2.25 per cent.

VALUES OF SINE ALPHA FOR VARIOUS POWER FACTORS AND WIRE SIZES.

| Wire Size, No. | Power Factor, Per Cent 100 | 95 | 90 | 85 | 80 | 70 | 60 |
|---|---|---|---|---|---|---|---|
| 4/0 | 0.89 | 0.70 | 0.60 | 0.51 | 0.44 | 0.30 | 0.17 |
| 2/0 | 0.82 | 0.60 | 0.49 | 0.40 | 0 32 | 0.17 | 0.04 |
| 0 | 0.76 | 0.52 | 0.40 | 0.31 | 0.22 | 0.07 | 0.05 |
| 2 | 0.61 | 0.34 | 0.20 | 0.10 | .0 | 0.13 | 0.26 |
| 4 | 0.45 | 0.15 | 0.02 | 0 08 | 0.17 | 0.31 | 0.43 |
| 6 | 0.31 | .0 | 0.13 | 0.23 | 0.31 | 0.45 | 0.56 |

FIG. 1—CHART FOR DETERMINING LINE DROP ON THREE-PHASE, 60-CYCLE, 220-VOLT SECONDARIES

regardless of the magnitude of the drop vector);

$\alpha = \phi - \theta$ for lagging power factor,

$\alpha = \phi + \theta$ for leading power factor,

$FCG$ = locus of $E_g$ when the line drop remains constant for different combinations of power factor, wire size, and loads.

The operation of the chart is shown by dotted lines in Fig. 1. From the load scale proceed vertically to the intersection with the desired power-factor line, then downward along the circumference of a circle (whose radius is the power factor line as intersected) to the base line. This gives the equivalent kilovolt-ampere load and hence is proportional to the current. Then proceed vertically to the line representing the desired wire size. The slope of this line is equal to the impedance per unit length, and the intersected vertical value gives the impedance drop per unit length for the particular case. Next proceed horizontally to the right to the desired distance line, then downward to the impedance drop scale. This determines the magnitude of the impedance drop vector ($E_d$ in Fig. 2) but not its direction.

Next find the factor corresponding to the wire size and the power factor from the table. This factor is the sine of the angle $\alpha$ (Fig. 2) and when multiplied by $E_d$, the impedance drop, gives $M$ (Fig. 2), the vertical component of the impedance drop vector with respect to the extended load voltage vector. It is evident then that the intersection on $HDI$ at a distance $M$ from the load voltage base will determine the position of the end of the impedance-drop vector and at the same time the line drop, as shown by concentric arcs similar to $FCG$. To accomplish this on the chart continue downward from the impedance-drop scale to the line representing the sine $\alpha$, then to the right to the intersection with the circle corresponding to the value of impedance drop as found above. This determines the position of the end of the impedance-drop vector ($E_d$) with respect to the concentric arcs which represent the various values of line drop and hence determines the line drop.

The arcs for scaling line drop may be constructed at equal increments of percentage drop or equal increments of voltage drop, whichever proves more convenient to use. Both the percentage drop and the voltage drop may be put on the arcs, but with most standard voltages this would involve fractional numbers, and for that reason only the percentage drop has been included on the chart shown. Likewise on charts for primary work it will be found more convenient to use some multiplier such as 20 or 50 in the impedance drop scale instead of using a scale of actual volts. This makes possible the use of small numbers

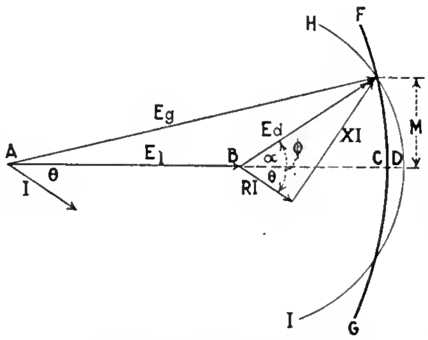


FIG. 2—LINE DROP CHART BASED ON ANALYSIS OF VECTOR DIAGRAM

and makes the chart somewhat easier to use.

If it is desired to construct a chart that can be used for both three-phase and single-phase, another scale may be added under the three-phase load scale to use for single-phase. Such a chart has been found very useful in rural distribution at 4,600 volts, where loads are handled on both single-phase and three-phase lines.

Detroit Edison Company,
Detroit, Mich.

## Safety Rules for Electric Crane Equipment

WHEN installing electric crane equipment the safety standards inaugurated by the Electrical Safety Conference* last fall should be kept in mind. The most important items covered are trolley conductors, overhead protection and disconnecting means, limit stops and brakes, phase reversal and low-voltage protection. The additions to the rules are given in part in the following paragraph:

### TROLLEY CONDUCTORS

*Location.*—Trolley conductors placed in the crane runway shall be located in such a position or so guarded that persons working on the crane or entering or leaving the crane cab are not likely to come into contact with live parts.

*Trolley Conductors on the Bridge.*—These conductors shall be so arranged or so guarded that hoisting cables cannot be brought into accidental contact with them and that persons cannot come into accidental contact with them. The installation of a light angle iron or its equivalent to prevent the hoisting cable from pulling against the bridge trolley of the conductors is considered sufficient protection.

*Monorail Conductors.*—Monorail runway conductors on I-beam or equivalent structural runways shall have a horizontal clearance from grounded metal parts of not less than 1½ in. if a wire is used for the conductor, or not less than 1 in. if rigid steel bars or shapes are used.

### OVERLOAD PROTECTION AND DISCONNECTING MEANS

*Main Fuses and Switch.*—Runway trolley wires for traveling cranes, or the feeder wires for other type of cranes, shall be protected by fuses or circuit breakers and controlled by a switch which can be locked in the open position. The fuses or circuit breaker and the switch shall be so located as to be easily accessible from the floor. If the circuit breaker opens all wires and is arranged so that it can be locked in the open position, the switch can be omitted.

*Bridge and Cab Switches.*—A switch shall be provided by which the operator can at all times and without leaving the cab disconnect all the equipment in the cab (except pilot lights) from its source of supply. There shall be a readily accessible switch by which all the bridge circuits and equipment (except pilot lights) can be disconnected from the runway trolley conductors or other source of supply. A single switch may in some cases serve both purposes provided it has means for locking in the open position.

*Individual Motor Protection.*—Where there is more than one motor on a single crane each motor shall be protected by fuses or by a circuit breaker or by overload relays controlling line contactors. If fuses are used, one fuse shall be provided in each conductor. If circuit breakers or overload relays are used, the number of trip coils shall not be less than that given in the following table:

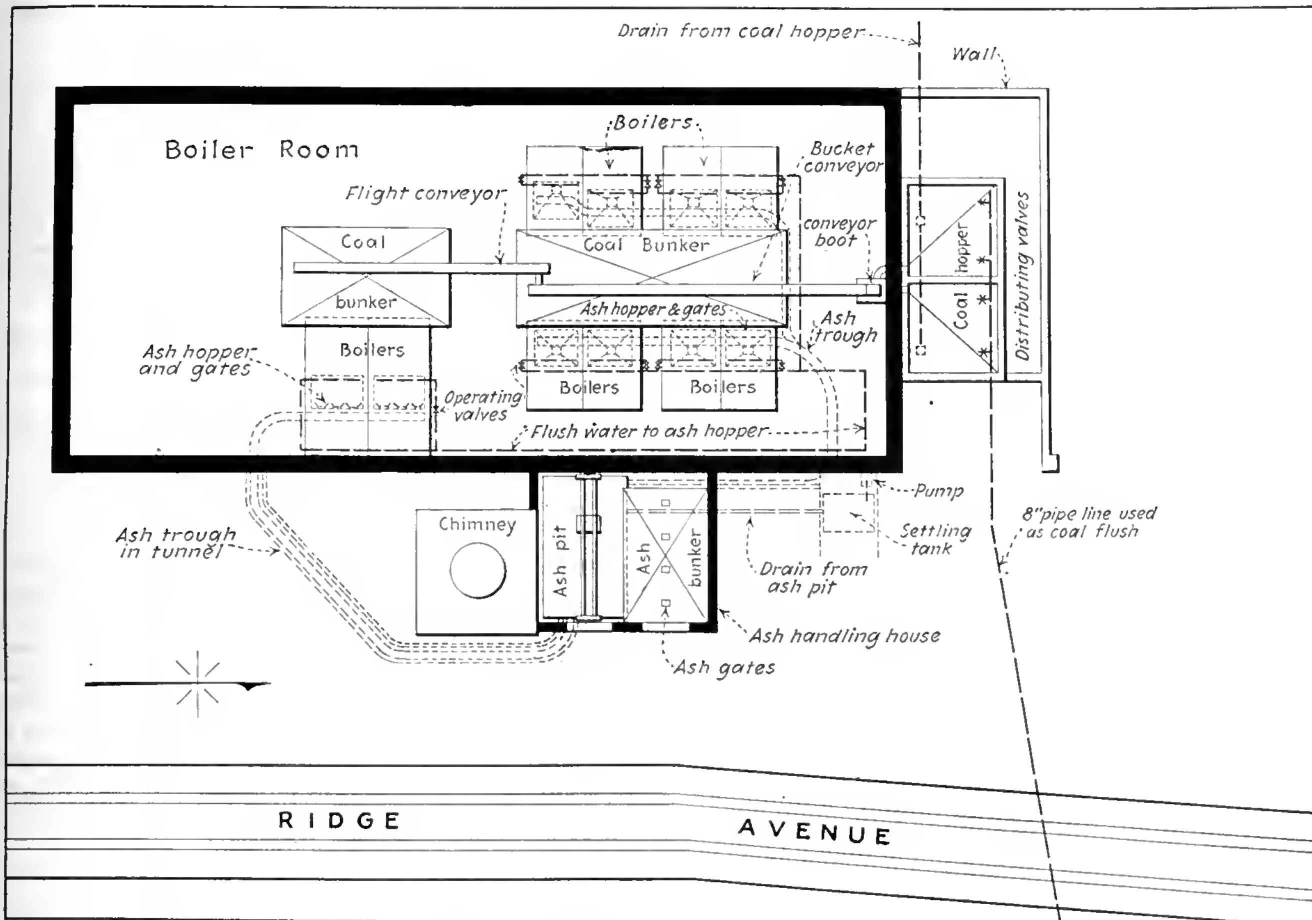
| System | Number of Trip Coils |
|---|---|
| Four-wire, two-phase, A.C. | Two (one in each phase). |
| Three-wire, two-phase, A.C. | Two (one in each outside conductor). |
| Three-wire, three-phase, A.C. | Two (one in each of two phases). |
| Two-wire, A.C. or D.C., ungrounded | One. |
| Two-wire, A.C. or D.C., grounded | One (in ungrounded conductor). |

### LIMIT STOPS AND BRAKES

*Limit Switch.*—Each hoist motor shall be equipped with a limit switch so placed and arranged as to disconnect the motor and apply the brake in time to stop the motor before the hook passes the highest point of safe travel. It is preferable to have the limit switch operated directly from the hook or block.

*Hoist Brakes.*—Each hoist motor shall be provided with a "magnet brake" so arranged that the brake will be applied when the power is cut off from the brake magnet. This brake shall have sufficient torque to sustain at least one and one-half times the full

*The Electrical Safety Conference is composed of five organizations, namely: the Associated Manufacturers of Electrical Supplies, the Electric Power Club, the National Workman's Compensation Service Bureau, the Bureau of Standards and the Underwriters' Laboratories. Its objects are the promotion by co-operative effort of the consistent development of manufacturing and installation practice with regard to accident hazards, the development of safety standards for construction and test and the interpretation and rendering uniform of electrical safety codes.



COAL AND ASHES ARE HANDLED BY WATER STREAMS IN THIS PLANT

rated load. Where a load brake is used, the "magnet brake" shall have sufficient torque to sustain at least full rated load.

*Additional Hoist Brake.*—All cranes which may handle hot metal or hazardous chemicals shall be provided with an additional brake on the intermediate shaft, which alone will meet the torque requirements of the foregoing paragraph. Cranes which have a cab on the trolley shall be provided with a brake for the trolley motion. The bridge travel shall be provided with a brake. The brakes specified for the last two cases shall be capable of producing a torque sufficient to retard at the rate of not less than one foot per second per second. When manually operated, this rate of retardation shall not require a force on the brake lever in excess of 100 lb.

*Phase Reversal.*—The runway feeders of electric cranes operated by polyphase alternating-current motors which have their direction of rotation dependent upon the proper phase relation shall be protected by a device such as a relay which will prevent starting of any of the motors on the crane if the phase rotation of these feeders is in the wrong direction.

*Low Voltage.*—Each crane shall be provided with a device which will disconnect all motors from the line on failure of power and will not permit any motor to be restarted until the controller handle is brought to the central position or a reset switch or button is operated. If a controller is arranged to return automatically to the "off" position when the operating handle is released, the low-voltage device may be omitted from that controller.

*Location of Controller.*—The control for the bridge and trolley travel shall be so located that the operator can readily face the direction of travel.

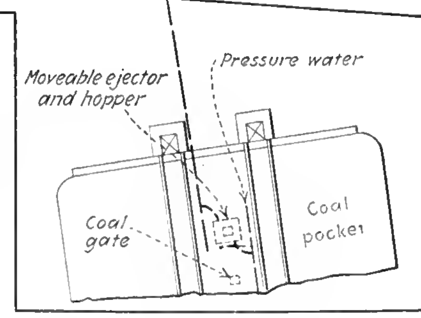
## Water Employed to Handle Coal and Ashes

TWO innovations for the removing of ashes and the conveying of coal are to be introduced in Philadelphia in connection with that city's water supply. In each case water will play an important part in the operation, and both installations are expected to facilitate the work and also reduce labor cost of conveying coal and removing ashes to and from the station.

Under the former method of operation the coal was delivered by railroad to a bunker, located some distance from the pumping station, and from this point was transferred to the station by means of motor trucks. Under this method the cost to the city of transporting the coal from the bunkers to the pumping station averaged about 20 cents per ton.



Under the new method it is estimated that the cost will be not more than 5 cents per ton, and from this there will be a much more expeditious conveyance of coal and the coal itself will be in much better condition for use owing to the cleansing action of the water.

Under the new method the coal will run from a bunker into a hopper. Near the outlet of the hopper are two pipes so arranged that the outlet of one pipe is on one side of the mouth of the hopper and the entrance to the other pipe is directly opposite to this, as shown in the accompanying illustration. A stream of water under 100 lb. pressure is driven through the pipe across the base of the hopper. As the coal comes into the hopper it is caught by the water and carried across the mouth of the hopper.

Push-cars back of the boilers are under the existing system used to remove ashes. The hot ashes are placed in these cars and transported to a receptacle, to be finally taken away by motor trucks. This method is now to be entirely abolished and the ashes will be removed from the boiler room by means of water. As the ashes come from the grates they will be dropped into a trough in which a stream of water flows. The ashes will thus be cooled and all dust eliminated. The water will move with sufficient force to carry the ashes to a bin so equipped that they will be drained. They will then be lifted by buckets to a hopper, from which they will be loaded into motor vehicles and taken away. This system has been very satisfactory.

Philadelphia, Pa. J. S. CLARKE.

## Phase Converters with Voltage Balancers

A PHASE converter with voltage balancer is used to equalize the phase loads and voltages of an unbalanced polyphase system. It consists of an alternating-current generator with special windings, acting as a voltage balancer, directly connected to a synchronous motor. In operating phase converters it is necessary to regulate automatically the current in the component fields of the voltage balancer in order that the generated voltage shall be of the proper magnitude and phase position for balancing. This regulation is accomplished by means of a P12 system of automatic regulation, which employs for each component field an exciter whose field in turn is supplied from an auxiliary exciter. The field current of each auxiliary exciter can be varied in strength and direction like that of the booster exciter under the KR system of voltage regulation.

The strength and direction of each auxiliary exciter field is regulated by a Tirrill regulator, which has, in place of a counterweight as in the KR system, a pilot coil to balance the pull of the operating coil. The pilot coil of each regulator is connected to one phase of the system being balanced—for instance, phase A-B; then the operating coil of one regulator is connected to phase B-C and that of the other to phase A-C. The connections are such that with all three phases of equal voltage the regulator arms are balanced, while any voltage distortion causes the regulators to operate in the direction to correct it. The following instructions for starting and shutting down phase converters are abstracted from the operating code of the Philadelphia Electric Company and apply in particular to the phase converter installation at the Schuylkill No. 2 station of this company.

### Starting Phase Converters

1. Make certain that all switches are in normal position for starting, namely: Reversing switch closed on "Start"; exciter knife switch closed; phase converter field selector switch closed; main oil switch open; bus selector oil switches open; auxiliary exciter field switch open; starting resistance short circuiting switches open; balancer exciter circuit breaker open; phase converter field break switch open; compensator switch open; starting switch open.
2. Start the main and auxiliary balancer exciters.
3. Close the bus selector switch.
4. Close the compensator switch.
5. Close the starting switch.
6. Operate the starting resistance switch three times, pausing after each operation to allow the current on the phase-converter ammeters to decrease to a minimum.
7. When the machine has come up to speed close the field break switch on the converter.
8. See that the phase-converter field current is adjusted to approximately 53 amp.
9. Open the starting switch and close the main oil switch at the same time. These switches are interlocked so that the starting switch opens before the main oil switch closes thus preventing any accidents from occurring.
10. Open the compensator switch.
11. Close the balancer-exciter circuit breaker.
12. Operate the starting resistance switch once. This disconnects the starting resistance from the field and connects the field to the exciter. The red indicating lamp on this control switch should light when the starting resistance switch is operated once.
13. Close the reversing switch on "Run," holding the control switch on until the starting switch opens and running switch closes. Should the running switch fail to close, do not test it before opening the main oil switch on the converter.
14. Examine the regulator and see that the differential relay switch is closed.
15. Select alternating-current and direct-current potential with the selector switches.
16. Close the P-12 regulator switches.
17. Close the auxiliary exciter field switch in the "up" position.

### Shutting Down

1. Open the auxiliary exciter field switch.
2. Open the main oil switch.
3. Operate the starting resistance switch once. This should disconnect the field from the exciter, connect the starting resistance to the balancer field and open the starting resistance short-circuit switches. The green indicating lamp on this control switch should light at this point.
4. Open the balancer exciter circuit breaker.
5. Open the field break switch on the converter.
6. Close the reversing switch on "Start."

## Boiler-Feed Pumps of the Plunger Type

ACCORDING to the operating code of the Philadelphia Electric Company, it is important in the starting of plunger-type boiler-feed pumps that the discharge valves be open; otherwise the water in the pump will be compressed to such a degree that it may seriously damage the pump. The code referred to gives the following rules for starting and shutting down pumps.

### Starting

1. See that discharge valve is open.
2. Open the suction valve.
3. See that the exhaust valve is open.
4. Open the drains on the steam cylinder and exhaust line.
5. Open the throttle valve and start slowly.
6. Turn on the lubricator.
7. Bring up the pump speed for the desired pressure.
8. Close the drains.

### Shutting Down

1. Close the throttle valve.
2. Close the suction valve.
3. Turn off the lubricator.
4. Close the suction and discharge valves, if shutting down for dismantling.

## Voltage Limits of Instrument Circuits

A STANDARD has been adopted by the Electric Power Club that insures the protection of instrument, meter and relay circuits on alternating-current switchboards. In order to reduce the voltage on instrument wiring, on the back of switchboard panels, which must necessarily be closely grouped, the standard practice as adopted by the club shall be to use voltage and current transformers for all instruments, meters and relays connected to circuits over 150 volts. This rule does not apply to relays and contactors in unattended stations where 440 volts will be allowed.

## Buffalo Company Opens Appliance Store in Substation

INTERIOR OF APPLIANCE SALESROOM

EXTENDING the use of electrical energy and the sale of appliances by intensive educational work led the Buffalo General Electric Company to add a complete and up-to-date appliance and equipment store to its substation No. 16, just completed in the northernmost section of the city of Buffalo. The company has a large appliance department in its main building in the business district of the city, but this is its first experiment in carrying the sale of apparatus and its educational work into the residential sections of the city.

Because, theoretically at least, there are many excellent reasons why it is practical to combine the service and appliance store with substations located in residential districts, central-station managers will watch results of the Buffalo experiment with interest. There is an apparent overhead economy in combining the substation and the merchandise store. Adding an attractive store front to the substation makes the latter a more attractive feature of the community. Besides being a convenience to nearby residents, such a store is a constant reminder of the adaptability of electricity to home uses. When educational work is combined with everyday merchandising, the results are almost sure to be beneficial to dealers in electrical supplies in the vicinity.

A feature of the new store is its large and well-lighted display windows. It is easily the best lighted and most attractive display in that part of the city, and this is likely to prove an incentive to merchants in the vicinity to provide themselves with better-lighted display windows.

The initial display used for the opening of the new station was one well calculated to give the public a better conception of the service of the company to the community. One window was devoted to the general idea that Buffalo is fortunate in having at its gates a wonderful source of hydro-electric power. On one side was a painting of Niagara Falls with a miniature reproduction of the generating plant of the Niagara Falls Power Company at the foot of the falls. Miniature high-tension lines were shown carrying the power from Niagara Falls to the distributing plant of the Buffalo General Electric Company at Buffalo. Then by means of miniature houses, parks and streets the display demonstrated how a modern community is electrically lighted.

WINDOW DISPLAY AT BUFFALO GENERAL ELECTRIC'S COMBINED SUBSTATION AND APPLIANCE STORE

## Maker-Utility "Tie-In" for Motor Advertising

AN EXPERIMENTAL newspaper advertising campaign was run for six weeks last fall by the Boston office of the General Electric Company to arouse the interest of business men in the electric motor drive. The number of inquiries received from these insertions has led to a broader development of publicity in the hope of obtaining the co-operation of utilities and local motor agencies in carrying forward the message of plant electrification. A second campaign, which is expected to run thirty-two weeks, was started March 27 in New England.

CO-OPERATIVE MOTOR ADVERTISEMENT

Representative daily papers in Boston, Springfield, Worcester and Portland will carry display advertisements, of which the one reproduced here is typical. The campaign will emphasize the economies of motor drive and invite the attention of manufacturing and central-station engineers to the problems of the "prospect." The Edison Electric Illuminating Company of Boston is co-operating in the local campaign. Similar developments are under way in Philadelphia and Chicago.

## Electrical Luncheons Prove Educational Value

IN THIS group of men are a hundred members of the Bloomington (Ill.) Rotary Club who were entertained by D. W. Snyder, Jr., general manager of the Bloomington & Normal Railway & Light Company at an electrical luncheon, which was followed by an inspection of the company's plant. The week previous a similar luncheon was given to the Young Men's Club of the city.

Commenting on the value of these contacts with local clubs, Mr. Snyder said: "I am very well pleased with the results obtained by the two luncheons. They have given these men, many of them leaders in their respective fields, an opportunity to see our problems from an operating standpoint. The interest they manifested in the machinery and equipment indicated that we operators often forget that our plant has a story which is very interesting to the public. Too often we see the apparatus merely as a physical machine and fail to capitalize its value from a publicity standpoint.

"The local newspapers gave us 48½ column-inches on these luncheons so I feel that we have done something which has helped us in getting our story across to the public."

## Twelve-Day Campaign Sells 140 Electric Washers

A HIGHLY successful sale of electric washing machines was recently conducted in Schenectady, N. Y., by W. M. Walsh, sales manager of that district of the Adirondack Power & Light Corporation. As a special inducement to buy during the twelve days of the sale a discount of $7.50 from the regular selling price was allowed, with a further discount of 5 per cent for cash. Deferred payments were also offered—$5 down and $12 per month.

After carefully outlining the advertising and selling program, the manufacturer's advertising department received an order for a big rush job.

### "Teaser Ads" Employed

Four days before the campaign opened a series of "teaser ads" appeared in the newspapers, increasing in size, reading matter and pulling power and exciting the curiosity of readers over the announcement to follow. Each of these "ads" declared, "You Need It in Your Home," and each day a line or two was added, increasing public curiosity and giving added hints of what was to come. As a result nearly every one read the six-column display "ad" on the opening day of the campaign, which answered the "teaser ads" by declaring that what the readers needed in their homes was a Western Electric washer and wringer, giving a full description of the service and opportunity being offered to the public.

The campaign slogan was used in all newspapers, truck and store advertising throughout the two weeks. Newspaper ads featured selling points of the washer with increased emphasis on the lapse of time and number of days remaining. During the campaign trucks carried banners

ROTARIANS READY TO INSPECT THE BLOOMINGTON COMPANY'S PLANT

advertising the slogan and selling terms, and the second week emphasized the closing date. The trucks decorated were those used in making deliveries and those used by the meter department, as they do the most traveling.

Tuesday and Wednesday of the first week the public address system of the Western Electric Company was brought to Schenectady to tie in with the campaign and help to put the story across. This was also used to good advantage in connection with the chamber of commerce membership drive.

A special display truck was put on the street which carried a message all its own. An old man was seen breaking his back and wearing out his knuckles over an old washtub and scrubbing board and turning an old-fashioned wringer. In the front a dainty young lady was reading while the electric washer did the washing. The moral was the subject of the principal banner: "Would you do this? Then don't let your wife do it. Buy her an electric washer and wringer, only $5 down." This amused and interested twenty thousand workers of the General Electric Company as they passed from work.

At night the feature truck gave its show on the main street at a busy corner and moved on to Schenectady's popular vaudeville house, where floodlights made it the center of attraction. A number of women mentioned the show when salesmen called on them, and people coming into the store to buy wanted to know where the Adirondack company found the clever old farmer, who was none other that L. E. Smith, one of the company's salesmen.

### Office Sales

Almost every one in Schenectady goes into the Adirondack office to pay his light and gas bill. Painted on the floor was a sign displaying the campaign slogan and terms, beyond which stood a washer mounted on a table in direct line of vision. Overhead, hanging between columns, were large signs driving home the campaign message.

The manufacturer furnished folders to accompany outgoing bills, lantern slides for use in motion-picture houses, newspaper illustrations and a quantity of window displays and placards.

The front window and three side windows contained displays in regard to the washer. The rest of the store display consisted of placards and washers placed at every conceivable advantage point on the sales floor.

The outside salesmen were backed by a competent inside selling and office sales force. During the campaign the inside selling force took the names and addresses, whenever possible, of "prospects" to whom they talked on the floor, and at each morning's sales conference these names were given to the outside salesmen, according to territory, for report in forty-eight hours. Good "prospects" were offered a free home trial, which generally resulted in a sale.

A campaign is always a strenuous affair, and there are always a thousand and one details to cover. Hence every one works at top speed under a high tension. When the day's sales are good every one is radiant and buoyant; when they are low the whole world is blue and despondent and every one else is to blame. Schenectady was no exception. The first day thirteen washers were sold; no doubt some had been held over for the opening by the outside salesmen. The next day brought five; Wednesday six. Things were not looking so bright. The first week closed with fifty sales, and every one was hopeful for another good Monday. The second week closed with ninety, twenty-seven sales being made Saturday, the last day—a total of 140 for twelve days.

The sales made by outside salesmen were seventy-nine, and sixty-one were made by the office sales force.

Campaign selling, Mr. Walsh believes, is best employed as intensive propaganda to stimulate interest and educate the public, and probably the greatest benefit is the business it brings in the future. The confidence and increase in capacity and vision accruing to a sales organization as a result of a job well done are factors having a direct bearing on increased business.

## The Potential Power Load on the Farm

A PROFITABLE field for devising new power applications is shown in the extent to which the farmer now uses power in his operations. Accurate data on the different types of farm power were recently presented by Prof. William Boss, chief of the division of agricultural engineering of the University of Minnesota, at the 1923 meeting of the Minnesota Engineering Society.

Of 3,611,325 hp. from animal, mechanical and electrical sources used in Minnesota alone, Professor Boss showed that only 6,000 hp., or one-sixth of 1 per cent, is from electrical sources. Farm automobiles and trucks form the biggest group, with animal power second. Professor Boss remarks that "very few people seem to realize the development that

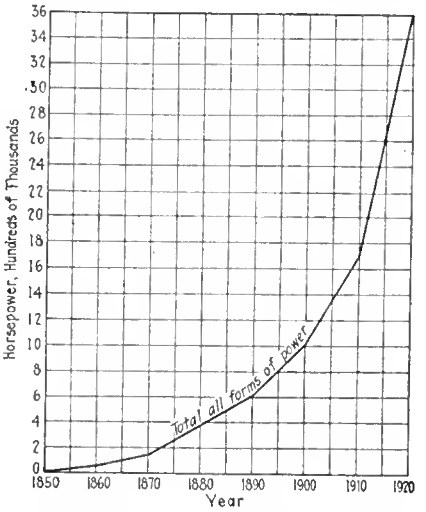

CHART SHOWING INCREASE IN USE OF POWER ON MINNESOTA FARMS

has taken place in the way of machinery and forms of power now available to the farmer. Minnesota is a comparatively young state, and it is interesting to study its development in the past twenty years and note what has taken place in the kind and amount of power used upon its farms."

The curve shows the development of the use of power on Minnesota farms and indicates the possibilities for the use of electrical energy if the proper equipment can be produced to do some of the draft work economically. The rapid growth of

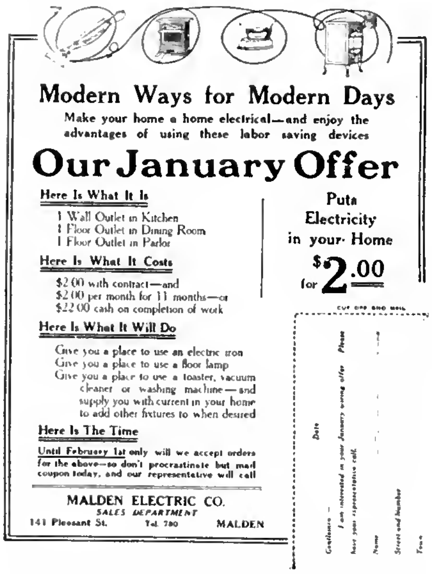
AVAILABLE FARM POWER IN MINNEOSTA IN 1920

| Type of Power | No. in Use | Hp. per Unit | Total Hp. | Per Cent of Total |
|---|---|---|---|---|
| Farm automobiles and trucks | 105,524 | 20 | 2,110,480 | 58.0 |
| Gas tractors | 14,799 | 12 | 177,488 | 5.0 |
| Gas engines | 61,039 | 2 | 122,078 | 3.5 |
| Windmills | 35,695 | 1 | 35,695 | 0.9 |
| Steam tractors | 6,300 | 25 | 157,500 | 4.5 |
| Horses and mules | 1,001,084 | 1 | 1,001,084 | 28.0 |
| Oxen | 1,000 | 1 | 1,000 | $\frac{1}{30}$ of 1 |
| Electric | | | 6,000 | $\frac{1}{6}$ of 1 |
| Total | 1,225,441 | | 3,611,325 | 100.0 |

the various forms of mechanical power and the relatively decreasing use of animal power is an indication of the trend. According to Professor Boss's figures, the use of electrical power did not begin until 1910 and has grown very slowly since then.

## Special Offer Brings 201 House-Wiring Contracts

RETURNS from the January campaign of the Malden (Mass.) Electric Company, which offered house owners an initial installation of three wired outlets for $22 as a base price and minimum installation, show that the company received 257



FOLDER GIVING DETAILS OF HOUSE WIRING OFFER WITH RETURN POST CARD

inquiries, which resulted in the obtaining of ninety-one contracts, representing $4,556 worth of work. Local contractors have reported to the company from their own accounts 110 installations, making a total of 201 meters added to the Malden company's service through the publicity material setting forth the above offer.

## Making Customer Owners of the Rising Generation

TO START the habit of customer partnership the Pine Bluff Company at Pine Bluff, Ark., is sending a certificate, as shown in the accompanying illustration, to each infant in its territory when the birth is recorded.

The certificate is good for $2.50 on the purchase of one or more shares of 7 per cent cumulative preferred stock of the company. In order to keep the company in the mind of the children as they grow up, an additional certificate will be sent to them on subsequent birthday anniversaries.

## Attractive Cottages for Station Operators

By E. A. Quinn

General Superintendent San Joaquin Light & Power Corporation, Fresno, Cal.

IT IS the aim of the San Joaquin Light & Power Corporation to obtain the services of operators at its Kerckhoff plant who can be relied upon to remain in the employ of the company for a reasonable length of time. To accomplish this the company has provided them with attractive and comfortable living quarters. The cottages at the Kerckhoff plant, one of which is shown in the accompanying illustration, were designed and the surrounding grounds were laid out with this thought always in mind.

The houses were built at a moderate cost, are electrically heated and are provided with electric ranges and water heaters. They are equal in every respect to modern city bungalows, and visitors to the plant upon seeing them, surrounded with lawn and shade trees, are almost willing to pay for the privilege of living in one and spending the delightful summer months in the picturesque Sierra Mountains.

The cost of making an attractive central camp for the operators and their families has been so small in proportion to the cost of the construction of dam, tunnel, power house, transmission lines, etc., that

OPERATOR'S COTTAGE AT KERCKHOFF PLANT OF SAN JOAQUIN LIGHT & POWER CORPORATION

it is really not noticeable in the total. The small sum thus spent makes for more reliable, efficient and contented employees.

## What Other Companies Are Doing

**Medford, Ore.**—The California-Oregon Power Company is organizing an entirely new department in central-station commercial activities. It is to be called the "new industries department" and it will be in charge of W. H. Crawford, formerly manager of the department of industries of the Portland (Ore.) Chamber of Commerce. The purpose of the new department will be to seek new industries and assist them in locating within the territory served by the power company in order to provide a greater sale of electrical energy.

**Milwaukee, Wis.** — Plans for a model electrical home, which will be a feature exhibit at the Home Building Exposition here, June 2 to 9, have been completed by the Architects' Small House Bureau. The house will be 44 ft. x 26 ft. in size and will have six rooms, bath and a model laundry. It has been designed to clear all trolley wires and low-hanging obstructions and will be specially constructed for moving, as it is to be given away on the last night of the exposition. The electrical and building industries have contributed all of the materials which enter into the construction of the house.

**Los Angeles, Cal.**—The first issue of "Edison Partners," an eight-page illustrated pamphlet sent quarterly to stockholders, employees and the general public by the Southern California Edison Company, has made its appearance. The purpose of the publication, according to President John B. Miller, is to acquaint all those interested in the welfare of the company with what it is doing to keep abreast of the rapidly increasing demands for electrical service in southern California.

$2.50 The Pine Bluff Company $2.50

Pine Bluff, Arkansas

This Certificate will entitle ______________________ to

Two Dollars and Fifty Cents ($2.50) to apply on First Payment of one or more Shares of 7% Cumulative Preferred Stock of The Pine Bluff Company

and make ______________________ a partner in the Electrical, Street Railway and Water Properties serving Pine Bluff, if presented within 30 days from date.

______________ 1923.

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Remodeling Power Plant for Fuel-Oil Use.*—Owing to the cost of obtaining and storing its supply of coal for the power plant at Pittsfield, the Berkshire Street Railway is making extensive changes to permit the use of fuel oil. Six boilers are being changed over, using the steam-atomizing system. A 100,000-gal. oil tank, which is filled from tank cars by gravity, provides an ample reserve supply of fuel.—*Electric Railway Journal,* March 24, 1923.

*Generating Costs in 50,000-Kw. Plant Reduced 35 per Cent.*—D. E. DRUEN.—Changes in operating practices and the building up of an efficient personnel, with an intimate knowledge of daily performance, have resulted in an average saving of $1,000 a day in the 50,000-kw. station of the Kansas City Railways. Although twenty years old, the station performance now compares favorably with that of many modern plants. To insure continuity of service a careful analysis was made, supplemented by additional information gathered from the station operators, revealing the various sources of the troubles. The repairs to auxiliary equipment, the overhauling and adjusting of machine governors, oil switches, disconnecting switches, control wiring, feed lines, boiler-feed pumps, etc., have eliminated the faults. Rigid rules have been laid down for the regular inspection of every unit, and operating methods have been adopted that not only tend to minimize the possibility of a service interruption but also make possible the re-establishment of service with the least delay. In regard to the organization side, an operating force of 150 men now constitutes the force, whereas 360 men were used before the plant was overhauled.—*Power,* March 28, 1923.

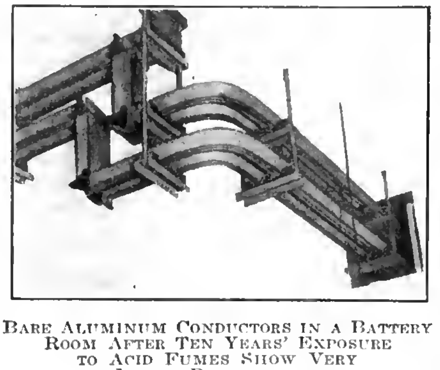
## Generation, Control, Switching and Protection

*Protection Against Overvoltages in the Iron and Steel Industries.*—H. M. TOWNE.—Overvoltages on electric circuits occur from four distinct causes. First is a direct stroke of lightning on the circuit itself; second, induced charge or stroke which may be caused by local or distant lightning flashes or which may exist in the nature of a bound charge caused by highly charged clouds above the circuit; third, gradual accumulation of static electricity by sand, sleet, hail and snow storms, and, fourth, internal disturbances—that is, overvoltages or surges originating from switching, sudden load fluctuations, resonant conditions, arcing grounds, etc. Some of the conditions found on the iron and steel electric systems and the relation of these conditions both to the possible hazard by overvoltages and to the class of protective equipment needed are briefly reviewed. The most important factors or requisites controlling the electrical behavior of arresters are analyzed.—*Proceedings of the Association of Iron and Steel Electrical Engineers,* March, 1923.

*Operating Alternating-Current Systems in Parallel.*—RALPH BROWN.—Conditions to be complied with when operating two power plants in parallel with and without transformers are pointed out. Parallel operation through frequency-changer sets is also considered—*Power,* April 10, 1923.

## Transmission, Substations and Distribution

*Bare Aluminum Conductors.*—An example is given of the usefulness of aluminum as material for heavy current busbars or for other bare station conductors. For such purposes aluminum can be used instead of copper with a very large cost saving. In addition, the weight to be supported by the insulators would be halved by such a substitution and other advantages are obtained in the direction of easier erection and better cooling. Data on the equivalent sizes of copper and aluminum bars, temperature rise, mechanical considerations and jointing are given.—*Electrician,* March 16, 1923.



BARE ALUMINUM CONDUCTORS IN A BATTERY ROOM AFTER TEN YEARS' EXPOSURE TO ACID FUMES SHOW VERY LITTLE DEPRECIATION

*Electric Oscillations in Transmission Circuits Caused by the Neutral Reactor.*—S. BEKKU. — The author treats the problem of electric oscillation in the transmission circuit where the neutral is grounded through the grounding reactor (in this case the Petersen coil) in a general manner, considering the line constants as concentrated. He first analyzes the single-phase system and then the three-phase system. Though a highly theoretical treatise the author visualizes the results by aid of numerical examples. The subject is considered under the following headings: Conventional representation of transmission lines, study of the steady-state phenomena, theory of symmetrical single-phase and three-phase transmission circuits, theory of faulty single-phase and three-phase transmission circuits, and miscellaneous disturbances in symmetrical three-phase transmission circuits.—*Researches of the Electrotechnical Laboratory, Tokyo, Japan,* No. 108.

## Units, Measurements and Instruments

*Well-Designed Hydraulic Testing Laboratory.*—A thoroughly modern test flume has been built at the Holyoke Water Power Company, in which any kind of draft tube or turbine setting can be tested out. A short description of the apparatus is given.—*Electrical News,* April 1, 1923.

*Teletachometer.* — C. WENDT. — An electric tachometer has been developed consisting of a direct-current generator with external excitation. It is made practically independent of the excitation voltage by using a highly saturated main field, a weak compensating field and a fixed magnetic shunt. Variations of as much as 50 per cent in the excitation voltage do not affect the constant field of the generator. It is claimed that short-circuits, external magnetic fields and heating do not influence the voltage. The voltage is directly proportional to the speed of the armature, so that any moving-coil voltmeter may be used to indicate the speed of the machine driving the tachometer dynamo. With its zero point in the middle of the scale of the voltmeter, forward and backward run can be remotely indicated and measured.—*A. E. G. Mitteilungen,* February, 1923.

## Illumination

*Color-Matching Units in the Industries.*—H. C. YOUNG.—A description is given of the proper lighting units to be used with the industries of lithographing, cotton, cigar and leather grading, dyeing and paint and chemical examination. It is pointed out that color-matching units are very desirable and practically a necessity in these industries.—*Central Station,* March, 1923.

*Electric Service in the Home.*—Electricity as an illuminant in the home has become such a necessity that few houses are now erected without wiring. The employment of electricity as a universal servant is, however, comparatively so recent a development that proper outlets have not been provided in the homes. This paper, which is a reprint of a booklet distributed by the Duquesne Light Company, should be of value in designing proper illumination for every room in the house. Diagrams for outlets are given for the front porch, lower hall, living room, dining room, library, kitchen, upper hall, bedroom, bathroom, sewing room, nursery, laundry, cellar, garage, pantry and sun parlor.—*National Electric Light Association Bulletin,* March, 1923.

## Motors and Control

*Three-Phase Motor Starter.* — H. FRANKEN. — Three-phase motors with wound rotors are started by closing the main switch for the stator and moving the starter for the rotor from the zero position slowly toward the full-run position. The paper deals with the question whether or not the starter should have an open circuit in its neutral position. Both constructions have their disadvantages, but it is found that a starter with an open-circuit zero position is liable to cause more severe trouble. The most satisfactory construction is an interlocked combination of main stator switch and rotor starter. An apparatus of this type, built like a drum-controller, is shown and explained. — *Elektrotechnische Zeitschrift*, March 8, 1923.

*Factors Influencing the Design of Woodworking Machinery.*—S. MADSEN. —Such factors as the adoption of high-speed steel, demands of greater economy, power and speed, the use of ball bearings and the direct application of the electric drive necessitate new standards for woodworking machinery. The author discusses these factors, summarizes the problems of driving and fitting cutter heads and tells how ball bearings and electric motors overcome many of them. The savings in power resulting from the use of ball bearings and motor-driven arbors are pointed out, and the paper includes tables of synchronous-motor speeds and other motor speeds.—*Mechanical Engineering*, March, 1923.

## Heat Applications and Material Handling

*Advantages of Basic Electric Furnace Iron for Castings to Resist Abrasion.*—L. J. BARTON.—Common white iron has many deficiencies, according to the author, inherent in the process of manufacture. The so-called synthetic iron, made in the electric furnace, has proved much more satisfactory for crusher jaws, ball-mill liners, roll shells and other parts. The characteristic properties of the common white iron made in the cupola and that made in the electric furnace are analyzed in order to show the superiority of basic electric furnace iron.—*Engineering & Mining Journal-Press*, April 7, 1923.

## Electrochemistry, Electrophysics and Batteries

*Some New Light on Electrolysis.*—E. R. SHEPARD.—The fundamentals of stray current distribution are considered in this article. Recent researches made with the earth-current meter have made possible the statement of these fundamentals in a way which was not possible before. Potential-difference measurements between underground piping systems and adjacent electric railway tracks or the earth's potential gradient are the main factor in determining electrolysis. It has been found that many of the assumptions heretofore made in regard to the flow of currents in pipes are erroneous. The author discusses the most important factors affecting electrolysis in order to modify or clarify the prevailing conceptions regarding the flow of earth currents in such a manner as will be helpful to those who are interested in this branch of engineering and research.—*Electric Railway Journal*, April 7, 1923.

*Generation of Suitable Voltages and Currents for Deep Therapy.*—C. H. HOLBEACH.—In the past few years considerable strides have been made in the improvement and simplification of X-ray equipment for both medical and industrial purposes. At the same time it is a noteworthy fact that the demands of X-ray workers are ever in advance of the apparatus at their disposal. It is for this reason that standardization is difficult, a design becoming obsolete almost as soon as perfection is approached. The comparatively sudden call for highly penetrative X-radiations of shorter wave length, involving the maintenance of 200,000 volts at the tube terminals for continuous running, has imposed many difficult problems on the designer and manufacturer. In the United States these difficulties have been solved to a great extent by the research laboratories of large electrical corporations.—*Journal of the Institution of (British) Electrical Engineers*, March, 1923.

## Traction

*All-Electric Passenger Service for New Haven.*—W. J. CLARDY.—Twelve new electric locomotives have been ordered by the New York, New Haven & Hartford Railway, and these will eliminate the steam locomotives for passenger service on the electrified section between New York and New Haven. These locomotives are of the 2-6-2 + 2-6-2 type equipped with six twin motors operating from an 11,000-volt, single-phase trolley or a 650-volt direct-current third rail. The motors have a combined rating of 2,016 hp. and will develop a tractive effort of 23,200 lb. at 32.6 miles per hour. The continuous rating is 15,800 lb. tractive effort at 39.4 miles per hour.—*Railway Age*, March 17, 1923.

*Further Accomplishments of Detroit Municipal Railway Systems.* — Three bulletins which deal with equipment, overhead and transportation are reviewed. How all of the practices of the Detroit United Railways have been changed under municipal operation should be of particular interest to railway men.—*Electric Railway Journal*, March 24, 1923.

## Telegraphy, Telephony, Radio and Signals

*The German Transcontinental Radio Station.*—E. QUACK.—A short and general description is given of the German sending and receiving stations for transcontinental radio-telegraph service. The two sending stations are at Nauen and Eilvese, the receiving posts at Geltow and Hagen. The corresponding American stations are at Riverhead and Rocky Point. A telegraphing speed of as high as 130 words per minute has been reached, which is contrasted against a maximum of thirty-five words through the Atlantic cable. A diagrammatic sketch shows the path a telegram takes from a sender in Germany to a receiver in America. — *Elektrotechnische Zeitschrift*, March 8, 1923.

*The Neutrodyne Receiver.*—A. RINGEL. — A new principle in radio-frequency reception for neutralizing capacity effects of tubes in which true radio-frequency amplification has been apparently obtained has been developed by L. A. Hazeltine. The equipment consists essentially of a tuned amplifier which is stable, neutralization being effected by small capacities connected from grid to grid of successive radio-frequency tubes. No potentiometer is necessary, and the tuning is quite simple.—*Wireless Age*, April, 1923.

*Radio Stations with Poulsen-Arc Generators.*—C. W. KOLLATZ. — This paper describes the latest navy and land radio stations with a Poulsen-arc oscillator for telegraph and telephone service. A 4-kw. Danish station and a modern 10-kw. German station are described in detail. By using the Pungs control an antenna output of as high as 50 kw. may be keyed directly with a very small key. The 10-kw. sender has a wave range of 2,600 m. to 9,000 m., an antenna current of 60 amp. for telegraphy and 35 amp. for telephony. The key current for the former is only 2 amp. — *Zeitschrift des Vereines Deutscher Ingenieure*, March 10, 1923.

## Miscellaneous

*High-Frequency Light Relay for Talking Motion Pictures.* — FRANZ AIGNER.—A perfect photo-electric cell or light relay must fulfill the three following conditions: (1) It must be inertialess, (2) it must be highly sensitive with a sufficiently large scale of sensitiveness, (3) it must utilize to the fullest extent the available wide gradation of a photographic emulsion. It has been suggested that the electromagnetic turning of the polarization plane of plane polarized light through either so-called "Faraday glass" or a cuvette containing carbon bisulphide be utilized, but the results obtained by this method have been found to be unsatisfactory on account of the distortion introduced by the self-induction of the controlling current coil. The author claims to have overcome this difficulty by using the same self-inductance as a means of tuning a high-frequency oscillating circuit and superimposing the acoustics according to well-known methods from radio telephony. The feasibility of this new method is explained mathematically. Theoretically the carbon - bisulphide would give better results, but for practical reasons the solid "Faraday glass" is preferable. A 200-cp. metal-filament lamp would give sufficient light and would obviate the disadvantages inherent in an arc lamp.—*Jahrbuch der Drahtlosen Telegraphie und Telephonie*, February, 1923.

# News of the Industry

Chronicle of Important Events and General Activities, Announcements and Reports of Association Meetings, Court Decisions and Commission Rulings and News of Electrical Men

## Floods in New England

**Public Utilities Escape Serious Damage Despite Unprecedented Overflow of Streams**

RECORD-BREAKING floods on the streams in northern New England early this week caused property damages estimated at millions of dollars, with widespread interruptions of railroad and highway transportation, especially in north central Maine, which were accompanied by temporary interruptions or curtailment of electric railway, lighting and power service. Advices by wire indicate that the water is subsiding in most of the affected districts and that the restoration of normal service will soon be accomplished.

President E. M. Graham of the Bangor (Me.) Railway & Electric Company says that the flow of the Penobscot River increased from a previous maximum record of 95,000 cu.ft. per second to 160,000 cu.ft. per second within a few days and that the hydro-electric stations of the company at Veazie and Milford had on Wednesday been out of commission for about three days. The Ellsworth plant of the affiliated Bar Harbor & Union River Power Company was shut down for about ten hours.

Nineteen out of twenty-one generators owned by these interests were under water. Trolley service was being run at about half schedule on Wednesday, and the company expected to restore electric service of all kinds to nearly normal by Friday night. Several weeks will be required to dry out the wet equipment on the system. Aside from minor washouts the dams and plants are in good condition. About three feet of water covered the operating floor at Veazie. No injuries to operators were reported on any of the Maine properties. On the Saco River high water caused inconvenience by backing up, necessitating considerable steam-plant operation.

The Central Maine Power Company sustained only moderate damage, according to late advices, although in some cases plants had to be shut down or operated at reduced rating for a time. A 110-ft. electric railway feeder tower at Augusta, Me., fell at a Kennebec River crossing Monday, but no one was seriously injured. Flood conditions in the Kennebec Valley were more troublesome than in the Androscoggin Valley, where excellent storage reservoir facilities helped in the control of excess flow.

At the New England Power Company's plant at Vernon, Vt., on the Connecticut River, output was cut down from 26,000 kw. to about 8,000 kw. on account of floodwater, and there was some reduction in capacity at other plants on the river. Little or no trouble was reported from the Deerfield River stations of this company, and J. Brodie Smith, vice-president Manchester (N. H.) Traction, Light & Power Company, wires the ELECTRICAL WORLD that high water on the Merrimac River resulted in no curtailment of service or damage to the generating stations of his company.

## High Pressure at Weymouth

**Turbine for Boston Edison's New Plant to Be Operated Under 1,200 Lb. of Steam**

WORK on the design of the new power station of the Edison Electric Illuminating Company of Boston, which is to be built on Fore River at Weymouth, about 8 miles from the company's L Street station, has now progressed sufficiently to permit an announcement of its more important characteristics.

The station will embody several new features in design—a 1,200-lb.-pressure boiler, a 2,000-kw., 1,200-lb. turbo-generator, the reheating of exhaust steam from the high-pressure unit and the use of house generators on the shafts of the main units.

A contract for two main units has been placed with the General Electric Company. Each turbine has a steam-end rating of 32,000 kw. at 350 lb. and has a direct connection to a generator rated at 30,000 kw. and a house generator rated at 2,000 kw. Negotiations are under way with the same company for a 2,000-kw., 1,200 lb. high-pressure turbine which will exhaust through a resuperheater into the main steam system at 375 lb. The way is left open for an ultimate installation of three of the high-pressure units, and the total exhaust of the three units will supply one main 32,000-kw. unit at 350 lb.

The four boilers are furnished by the Babcock & Wilcox Company and will operate with a total steam temperature of 700 deg. F. High-pressure economizers will be used with both the three 375-lb. boilers and the 1,200-lb. boiler.

The adoption of 1,200 lb. pressure for the initial stage requires the working out of many new problems in the design of the station. The work is under the supervision of I. E. Moultrop of the Edison Electric Illuminating Company of Boston, and Stone & Webster, Inc., have been engaged to design and build the plant.

## Water-Power Bill Fails Too

**Governor Smith's Niagara and St. Lawrence Measure Shares Fate of Utility Bills**

WITH the New York State Legislature speeding up to permit adjournment on Friday of this week, the water-power bill favored by Governor Smith, which provided for state development, distribution and control of power from the St. Lawrence and Niagara Rivers, went down to defeat by a majority of ten in the Assembly on Tuesday despite a special message from the Executive Mansion urging its passage. Thus the whole program of the Democratic administration on utility regulation and power development goes over for the verdict of the electors next fall, and its ultimate triumph or defeat will depend on which party gets a majority in the Assembly then to be elected. The Senate, which is Democratic, holds over for another year.

An important water-power measure has been introduced at Albany in the form of a constitutional amendment, presented by Senator Ferris, which provides in effect that not to exceed 3 per cent of the forest preserve may be used for the construction of power stations, the location of transmission lines, the building of dams and allied purposes.

Under present constitutional limitations, whether the state itself, private corporations or the United States government under the provisions of the water-power law were to develop hydro-electric energy at the St. Lawrence, it would be impossible to transmit it in a direct route to the capital district and New York City, because under the provisions of the New York State Constitution not a stick of timber could be cut on the Adirondack preserves for any purpose, and this would mean that transmission lines from the Long Sault Rapids would by force of necessity be carried either by way of Plattsburg and thence southerly or via Malone, Ogdensburg, Carthage and Utica around the present Adirondack reservation.

## Ford Accepts Conditions

Henry Ford has accepted the conditions imposed by the Federal Power Commission in connection with the extension of rights to generate power at the High Dam on the Mississippi between St. Paul and Minneapolis. The commission also has approved informally a contract wherein Mr. Ford agrees to sell all surplus power to the Northern States Power Company at 2½c. per kilowatt-hour.

## Steam Locomotives to Go

**Virginian Railway Places Contract with Westinghouse for 213 Miles of Single-Phase Electrification**

A CONTRACT for the electrification of 213 miles of its track, crossing the Alleghenies between Roanoke, Va., and Mullens, W. Va., has been placed with the Westinghouse Electric & Manufacturing Company by the Virginian Railway. This is nearly half the line. The order, which includes construction of electric locomotives, power house, transformer station and apparatus, involves an expenditure of $15,000,000. The alternating-current, single-phase system will be used at 11,000 volts. Power will be supplied by a 90,000-hp. generating plant to be erected on the New River, and the voltage of the main transmission line will be 88,000.

The Virginian, which was built by the late Henry H. Rogers, has long been known as a leading exponent of mass transportation, that is, the handling of traffic by the largest and heaviest trains instead of by the equivalent in smaller trains.

Frank H. Shepard, director of heavy traction for the Westinghouse company, said, in discussing the electrification, that although the Virginian is moving 7,000,000 tons of coal a year, this is not sufficient to meet the growing demands of the area served. The limit in power of steam locomotives has been reached, and after a thorough study it decided to electrify this mountain-grade division.

"The chief advantage of electric operation lies in the greater power that can be applied to each train," Mr. Shepard said. "Three of the largest steam locomotives in use on the Virginian, the articulated Mallet type, are used to haul 5,500-ton trains over the grades, but their combined power does not exceed 7,000 hp. and their speed on the grades is only 7 miles an hour. The new electric locomotives, developing 20,000 hp. per train, will haul 9,000-ton trains up the grades at a rate of 14 miles per hour, and it will be entirely practicable in future to increase this power so that 12,000-ton trains can be handled at the same speed.

"A feature of the electric locomotive," he added, "will be the use of regenerative braking on the down grades. This method of braking will not only reduce wear on the brakeshoes and wheels and improve operation, but will also save 15,000,000 kw.-hr. of electrical energy per year."

## Columbia River Investigation to Begin Soon

Definite steps to begin the investigation authorized by Congress of the Columbia River Basin in the State of Washington with respect to the reclamation of several million acres of lands included in it have been taken by the Interior Department. Much projected hydro-electric development is awaiting the outcome of this investigation.

Assistant Secretary of the Interior F. M. Goodwin, a member of the commission named by Secretary of the Interior Work to conduct the investigation, will join Director A. P. Davis of the Reclamation Service, another member of the commission, at Spokane in a few days for the purpose of outlining plans for the field work. Mr. Goodwin will make a short trip over some of the routes of the basin where it is proposed to construct diversion dams and other works, after which he will go to the Umatilla Rapids district in Oregon, Congress having appropriated the sum of $50,000 for the purpose of investigating its reclamation possibilities.

## Government Promotes Nitrate Manufacture

A campaign being launched by the Department of Commerce with the idea of freeing American consumers from the domination exerted by the Chilean nitrate producers is to be under the immediate direction of Harry A. Curtis, a chemical engineer who served with the nitrate division of the Ordnance Department during the war and was chief of the Sheffield Experiment Station, where work was done on the problems in connection with the Muscle Shoals nitrate plants. He is to be assisted by William H. Walker of the American Farm Bureau Federation.

This announcement, made on May 1 by Secretary Hoover, marks the opening of active work on the nitrate problem. The investigation resolves itself largely into a study of means whereby the fixation of atmospheric nitrogen can be undertaken in this country. While it will be necessary to learn as accurately as possible the minimum price at which Chilean nitrate could be laid down at American ports, it is believed probable that no extensive investigation of the Chilean industry will be undertaken. It is held that the situation is one which can be met best by establishing sources of nitrogen within our own borders. Every effort will be made, it is believed, to induce private enterprise to undertake the manufacture of atmospheric nitrogen. If that should fail, none would be surprised were a recommendation made for large-scale experiments to be undertaken by the federal government.

**E. F. W. Alexanderson of Schenectady, consulting engineer of the General Electric Company and chief engineer of the Radio Corporation of America, has appealed to the ELECTRICAL WORLD to help enlist the aid of men of the electrical fraternity in the search for his kidnapped son, Verner. He is described as a fair-haired, blue-eyed, chubby six-year-old boy. Possibly this message may reach some one whom the radio, the "movies" and the newspapers have failed to reach.**

**The boy was kidnapped April 30; but, in spite of nation-wide publicity, he has not, as the ELECTRICAL WORLD goes to press on May 3, been found.**

## Hetch Hetchy Distribution

**Power from San Francisco Plant May Be Sold to Private Companies and City Network Postponed**

TEMPORARY distribution by private corporations in San Francisco of the power that will be available upon the completion of the Hetch Hetchy project in about eighteen months has been suggested by City Engineer M. M. O'Shaughnessy in a report to the public utilities committee of the Board of Supervisors. Four proposals in all were made to the board in response to a request for recommendations to enable it to determine upon the best policy for the city to adopt.

Mr. O'Shaughnessy deferred making any definite recommendation, but emphasized the desirability of a temporary system of private distribution by pointing out the serious difficulties to be overcome before the city can own and operate its own distribution system. It was stated that officials of the Pacific Gas & Electric Company have signified a willingness to negotiate for the purchase of the power produced by the city's project.

An additional bond issue of $30,000,000 will be needed to complete the Hetch Hetchy work, and if arrangements for private distribution can be made, the city's financial and construction resources should be devoted to the completion of the major project. An expenditure of at least $17,000,000 would be involved in any municipal distribution system, and such an outlay at this time would virtually make impossible the thirty-million-dollar bond issue needed for additional construction. Under any plan of disposing of the power it is estimated that the city will be assured of a revenue of $1,500,000 to $2,000,000 a year for the 300,000,000 kw.-hr. that will be available for distribution to consumers when the plant is completed.

### FOUR ALTERNATIVE PROPOSALS

Following are the four alternative proposals as stated by Mr. O'Shaughnessy in his report to the Board of Supervisors:

1. That the city distribute the power by its own system, which would involve the building of transmission lines, construction of substations and tearing up of streets, with much expense in addition to the $17,000,000 that the system itself would cost.

2. That the city distribute the power itself, following purchase of the existing distribution system of the Pacific Gas & Electric Company.

3. That the city sell the entire Hetch Hetchy output to a private corporation, with an agreement for redelivery to the city of the 40,000,000 kw.-hr. that would be required of a total annual production estimated to reach 300,000,000 kw.-hr.

4. That the city distribute the power under an agreement with a private corporation by which the latter would act as agent of the city.

## Rulings by Power Board

**Rule Adopted for Permits to Municipality Hits Louisville—Expiration of Priorities**

PRELIMINARY permits for water-power developments may not be granted to municipalities until they can show legal authority for prosecuting the work. An opinion to that effect has been issued by the chief counsel of the Federal Power Commission and has been approved by the commission itself.

This ruling is certain to have a far-reaching effect. In many instances power developments have been delayed because of the action of municipalities in attempting to obtain the rights preferentially under the water-power act. In this opinion, however, it is held that "a municipality is not a competent applicant unless it is empowered by the laws of the state in which it is located to carry on the business of developing, transmitting, utilizing or distributing power, and that a city or other political subdivision is not competent if it is not empowered under the existing laws of its state to make the development applied for." The chief counsel pointed out that before an applicant for a license can receive a preliminary permit the applicant must be competent to receive a license. A preliminary permit, he holds, may not be given for the purpose of enabling an applicant to qualify as to competency.

This opinion was sought in connection with the application of the city of Louisville for a preliminary permit and license for the development of power at the government lock and dam in the Ohio River at Louisville. The municipality is proposing to undertake an enterprise which involves the distribution of power over a wide area in two states. As a result of the legal opinion it is anticipated that the commission will deny the application of Louisville.

The commission has approved an opinion by its chief counsel to the effect that "if a permittee within the time prescribed by his permit has filed an application for a license in proper form and accompanied by the required data, his priority will not expire with the end of the period of the permit, but will continue for such time as may be used by the commission in granting or denying the application; that the priority attaches to and inheres in the application for license and continues until the application is disposed of by withdrawal, denial or the grant of the license."

## Airplane Used to Map Route of New Coatesville Line

An airplane was called into use in a recent survey of a projected transmission line from the McCall's Ferry power plant of the Pennsylvania Water & Power Company at Holtwood, Pa., to Coatesville, Pa. The airplane flew in a bee line at a height of two miles and a photograph was taken every few seconds. After the flight was completed and the pictures had been developed they were pieced together and an absolutely accurate bird's-eye map of the route, showing a strip 5 miles wide and about 30 miles long, resulted. A great saving in time and effort was thus accomplished.

The new transmission line, which is to supply power to the Chester Valley Electric Company, will be operated first at 73,000 volts, but is designed for ultimate operation at 110,000 volts. It will be a double-circuit steel-tower system of the best type. A new substation is to be built by the Chester Valley company at Newlinville, near Coatesville and in proximity to the steel mills which are the company's largest power customers. The substation and the transmission line will together cost more than a million dollars. A long-term contract with the Pennsylvania Water & Power Company will, F. W. Harris, general manager of the Chester Valley Electric Company, announces, take care of the power requirements of Coatesville and its vicinity for many years to come. The plan is in accordance with the modern idea of superpower and will obviate the building of a new generating station by the Chester Valley company.

# How Alabama Company Can Use Lock 17

**Will Furnish Several Thousand Horsepower at Full Flow and Act as Voltage Booster in Low-Water Season—Tuscaloosa District Will Benefit—If License Is Granted, Work Will Be Pushed**

THE petition filed with the Federal Power Commission by the Alabama Power Company for a license to develop power at the government's navigation dam, Lock 17, on the Warrior River, about 20 miles above Tuscaloosa, Ala., and the similar petition filed with the Alabama Public Service Commission will, President Thomas W. Martin appears confident, be granted, although a petition has been filed with the commission against the project. This petition has been set for hearing on May 9. The sponsors are not known, but it is presumed to emanate from supporters of Henry Ford's scheme for exploiting Muscle Shoals.

Although the dam at Lock 17 is 63 ft. high and 1,200 ft. long, the flow of the Warrior is so varied that its use for the development of power has long been considered economically impracticable, and officials of the Alabama Power Company say that any power development of any kind at that point is possible only because of the company's ability to tie in the proposed plant at Lock 17 with its six other hydro-electric and steam generating stations. At certain seasons of the year the Warrior is a raging torrent, capable of generating several thousand horsepower of electricity, and at other seasons the stream flow is barely sufficient to turn the waterwheels. During the latter periods, however, it could do what is known as "float" the generators on the line, making the plant valuable as a voltage booster for the Tuscaloosa district, which is at the end of a single-circuit line. The proposed use of Lock 17 by the company is considered a boon to Tuscaloosa, as it will be the means of bettering the power service of that city.

One reason for the belief that the application will be granted is the fact that the Alabama Power Company is the sole agency in the state with sufficient reserve steam-plant capacity to make use of seasonal power such as that at Lock 17. It is pointed out that

LOCK 17, PROPOSED SITE OF PLANT TO BE ERECTED BY THE ALABAMA POWER COMPANY TO SERVE WESTERN ALABAMA

when the water is low in the Warrior the shortage could be supplied from the company's reserve steam plants at Gorgas or Gadsden or from the Muscle Shoals plant leased from the government, and that when there is sufficient water in the Warrior to operate the Lock 17 plant, its use would be the means of saving many tons of coal. In addition, the government would derive some revenue from the use of this power, which has been going to waste since the completion of the dam in 1915. A power house would have to be constructed by the company and waterwheels installed, calling for a large expenditure of money, giving employment to several hundred men and ultimately resulting in the payment of taxes to the state and county on the investment made.

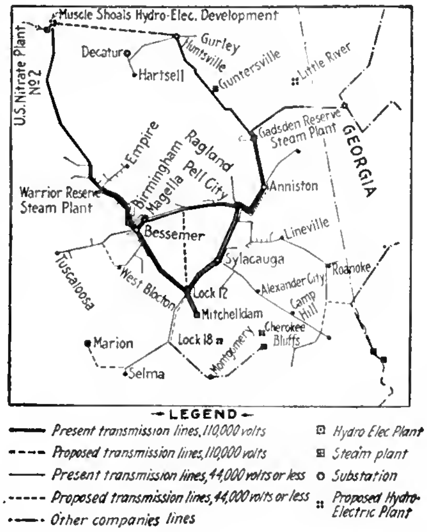
No details are available as to the size of the proposed development, it being necessary for the engineers of the company to work these out in conjunction with the Federal Power Commission. It is understood, however, that work will be undertaken as soon as after the granting of a license as is found to be possible.

## Fight on Alabama Link from Sheffield to Huntsville

A fight is brewing before the Alabama Public Service Commission on the petition of the Alabama Power Company to erect a transmission line from Huntsville to Sheffield, where it would connect with the Muscle Shoals steam plant and thus complete a "power loop" in Alabama. The petition was to have been heard last week, but was postponed until May 9 on the protest of the city of Sheffield and the Sheffield Chamber of Commerce. Objections to the new line were raised at Sheffield on the theory that its erection would prejudice the bid of Henry Ford for Muscle Shoals.

After Sheffield intervened in the case, cotton mills of Huntsville, Decatur and Albany, Ala., and the chambers of commerce of these cities sent telegrams to the commission protesting against postponement of the hearing on the ground that the new line is needed to supply in an adequate manner electrically operated industries in the Tennessee Valley.

According to the announcement by the Alabama Power Company, the line it proposes to build is simply a connecting link to make a complete circuit so that Huntsville and the "Tri-Cities" may receive power from either direc-



HOW LINK FROM MUSCLE SHOALS TO HUNTSVILLE WOULD COMPLETE RING

tion. Having a complete circuit insures continued service to customers in case there should be an accident to one of the lines.

## Wisconsin Advocates of Water Power Oppose Delay

Thousands of dollars would be lost and needless waste of thousands of tons of coal each year would be entailed by the passage of the water-power survey bill sponsored by E. J. Gross of Milwaukee, engineers asserted at the first hearing on the measure by a joint committee of the Wisconsin Senate and Assembly, which listened to arguments on April 25.

The opposition to the bill, which passed the Assembly by a vote of 54 to 7, waxed hottest over a provision which would prohibit further development of water-power sites for six years. No objection was voiced to that section, of the bill providing for a survey of water-power sites, though it was maintained that a thorough investigation would necessitate a much larger expenditure than the sum of $25,000 which the bill carries.

Prof. Daniel W. Mead, Madison, consulting engineer and a leading authority on water-power development in the United States, raised the principal objections to the bill, which, he said, could accomplish no useful purpose and meant a halt in the material development of the state. It would entail a loss of millions in money to the state and to its citizens in interest on moneys already invested, in consequential losses of taxes and in the unnecessary consumption in the proposed six-year period of at least a million tons of coal.

"It is to the interest of all citizens and all industries in the state," declared Professor Mead, "that the development of water powers be encouraged, not threatened. They conserve coal, withdraw coal traffic from the railroads, add to the local and state income, decrease the cost of light and power, induce manufacturing and add to the comfort and convenience of all the people. No man who has an intelligent knowledge of our natural resources would favor the passage of the bill."

## Cost of Electricity

### Government Figures Show It to Be the One Important Commodity to Decrease in Price

THE Bureau of Labor's last quarterly statistics on the changes in the cost of living in the United States as compared with basic prices in 1913 carry an interesting footnote. Hitherto "fuel and light" have been lumped together in the table and have shown a very large increase, comparable to that in other staple commodities. In the statistics just issued, which include the figures for March, 1923, this manifest injustice to the producers and distributors of electrical energy is remedied by a line added after the total and showing an actual decrease in the price of energy as compared with December, 1914. "Fuel and light" combined show an increase in the last quarter of 86.2 per cent, compared with 42 per cent for food and 74.4 per cent for clothing, but electricity not only shows a decrease of 2.4 per cent but has shown an increase only once in the last six years—one of 1.2 in December, 1920.

The information contained in the Bureau of Labor's statistics, which are a summarization of the figures for thirty-two cities computed on a 1913 basis, is derived from actual prices which have been obtained from merchants and dealers for each of the periods named.

CHANGES IN THE COST OF LIVING IN THE UNITED STATES, 1913 TO MARCH, 1923

| Item of Expenditure | Per Cent of Increase from 1913 (Average) to— Dec. 1917 | Dec. 1918 | Dec. 1919 | June 1920 | Dec. 1920 | May 1921 | Sept. 1921 | Dec. 1921 | Mar. 1922 | June 1922 | Sept. 1922 | Dec. 1922 | Mar. 1923 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Food | 57.0 | 87.0 | 97.0 | 119.0 | 78.0 | 44.7 | 53.1 | 49.9 | 38.7 | 41.0 | 39.8 | 46.6 | 42.0 |
| Clothing | 49.1 | 105.3 | 168.7 | 187.5 | 158.5 | 122.6 | 92.1 | 84.4 | 75.5 | 72.3 | 71.3 | 71.5 | 74.4 |
| Housing | .1 | 9.2 | 25.3 | 34.9 | 51.1 | 59.0 | 60.0 | 61.4 | 60.9 | 60.9 | 61.1 | 61.9 | 62.4 |
| Fuel and light | 24.1 | 47.9 | 56.8 | 71.9 | 94.9 | 81.6 | 80.7 | 81.1 | 75.8 | 74.4 | 83.8 | 86.4 | 86.2 |
| Furniture | 50.6 | 113.6 | 163.5 | 192.7 | 185.4 | 147.7 | 124.7 | 118.0 | 106.2 | 102.9 | 102.9 | 108.2 | 117.4 |
| Miscellaneous | 40.5 | 65.8 | 90.2 | 101.4 | 108.2 | 108.8 | 107.8 | 106.8 | 103.3 | 101.5 | 101.1 | 100.5 | 100.3 |
| Total | 42.4 | 74.4 | 99.3 | 116.5 | 100.4 | 80.4 | 77.3 | 74.3 | 66.9 | 66.6 | 66.3 | 69.5 | 68.8 |
| Electricity * | -4.8 | ** | ** | -2.4 | +1.2 | ** | ** | ** | -1.2 | -1.2 | -2.4 | -2.4 | -2.4 |

* This line shows the percent of increase (+) or decrease (-) in the price of electricity at dates mentioned as compared with price in December, 1914. These figures are based on simple averages of primary rates.
** Same as in December, 1914.

## Welding Men Meet

**Progress in the Electrical Process Is Shown in Report—Code Recommendations Made**

WELDING storage and pressure tanks, rail joints and structural work, cast-iron welding and resistance welding were the most interesting of the technical subjects discussed at the annual meeting of the American Welding Society, held in New York April 24 to 27. Past progress in the various branches of welding and plans for future investigation and developments were outlined by the different speakers, and the electric process was shown to be advancing rapidly.

A report of the committee on welded pressure vessels was made by H. L. Whittemore. This report told of tests and conclusions therefrom which will be submitted to the boiler code committee of the American Society of Mechanical Engineers as proposed rules for welded boilers. The committee found that double-V welds are at least 25 per cent stronger than single-V welds on longitudinal seams. The weakest double-V weld tested had a strength of over 90 per cent of the base-plate strength. The maximum was 113 per cent. This type of weld was suggested as mandatory for longitudinal seams. For welded boilers the committee recommended the use of low-carbon steel (not over 0.15 per cent) with a tensile strength not over 55,000 lb. To test welded vessels it was recommended that the pressure be raised to one and one-half times working pressure, and that after this the vessel be hammered and then the pressure be raised to three times working pressure. An exception was made for cases involving complicated attachments, when the final pressure need be raised to only twice working pressure.

### Electric Welding Reviewed

The committee on welded rail joints, of which Dr. G. K. Burgess, the newly appointed head of the Bureau of Standards, was chairman, reported that a program had been developed, financial support assured and experimental work well started.

A complete review of the present development of electric welding was contained in the talk of W. L. Warner. He touched on the high points in the various phases of welding practice and research. In addition, he gave a list of the latest reports and papers.

Higher welding currents, use of better material in electrodes, coated electrodes, forging and heat-treating the weld, welding cast iron, monel metal and brass were some of the advances in practice which were discussed. Application of welding to oil storage tanks and to pressure vessels was said to have many advantages over riveting.

In the field of resistance welding the trend is toward higher voltage and current, lighter pressure and shorter time for welding, according to Herman Lemp. This form of welding is used successfully over a large range of work. For instance, two 24-in. seams are welded on automobile rear-axle housings requiring 1,000 kw. Seam welds are made in 0.025-in. plates of low-carbon steel, tool steel or brass. The welded portions can subsequently be swaged and rolled. An application to very small parts is in welding together tungsten and copper wires for vacuum tubes.

T. F. Barton of the General Electric Company was elected president of the society for the ensuing term. An increase in membership from 595 to 684 was reported. C. A. Adams was re-elected director, H. M. Hobart first vice-director, A. S. Kinsey second vice-director, and W. Spraragen secretary of the American Bureau of Welding, the society's research department.

## Long-Distance Carrier-Current Record

**Radio-Telephone System Placed in Operation on 200-Mile Transmission Line Between Pit River No. 1 and Vaca Substation Will Use 220,000-Volt Lines**

ON APRIL 11 the Pacific Gas & Electric Company placed in operation a carrier radio-telephone system over its 202-mile transmission line between Pit River No. 1 plant and Vaca substation. The system utilizes the twin-circuit line between the two points built for 220,000-volt operation and will be used for directing the operation of the stations under both normal and emergency conditions. Wire communication has been carried on heretofore, but only by a very indirect route requiring five relays and necessarily subject to error and delay.

Uncompleted Carrier-Current Installation at the Pit River No. 1 Power House

The transmitting equipment is of the usual vacuum-tube telephone transmitting type similar to that used by high-power broadcasting stations. Four 250-watt and one 50-watt radiotron tube are used. Two of the tubes are used as oscillators and two as modulators, with the 50-watt tube as a speech amplifier. Wave lengths between 4,500 m. and 23,500 m. were tried and 9,200 m. was selected as the most satisfactory. At this wave length the radiation is 6 amp., and there is no interference from telegraph stations. The system is coupled to the transmission line through a single-wire antenna about 1,800 ft. long. This wire is attached to the twin vertical-circuit steel towers at a point on the center line of the tower and at the elevation of the middle arm.

The receiving equipment consists of a Colin B. Kennedy Corporation type 110 Universal receiver and a Western Electric No. 10-A loud speaker with two stages of audio-frequency amplification. Calling is accomplished by mounting a microphone in the horn of the loud speaker which when the calling circuit is completed will oscillate and "howl" in much the same manner as the ordinary telephone when the receiver is placed against the transmitter. This gives a loud note which is clearly audible in all parts of the station. Ordinarily this method of calling is not used as the operator is within hearing distance of the loud speaker. The system is arranged for simplex operation, and all that is necessary is to throw a small telephone switch which energizes a contactor to connect either the transmitting or receiving set to the antenna, thus permitting talking or listening.

The system, which was installed under the direction and supervision of Dr. Leonard Fuller, radio engineer, establishes a new record for distance for carrier radio-telephone communication. Operation has been very satisfactory, and tests indicate that normally one-half of the transmitting power of the set would be sufficient to carry on successful communication.

## A. I. and S. E. E. Discusses Mine Electrification

The factors entering into the proper selection of coal-mine hoists and methods for reducing power bills were discussed in a paper presented before the Association of Iron and Steel Electrical Engineers at Pittsburgh on April 27 by F. W. Cramer and A. W. MacDonald of the Cambria Steel Mill. Frequently in the selection of a hoist the initial cost has a direct bearing on the final decision, they asserted. The cost of power often influences the style and type of hoist drive purchased. In a mine completely electrified the authors thought that a 1,000-hp. hoist motor had no appreciable effect on the demand charge when central-station power was purchased. They also demonstrated that complete electrification means greater production and lowest cost per ton of coal mined.

The straight induction motor, the water-rheostat control and the Ward

Leonard motor-generator system are the typical hoist drives, the paper said. The induction motor represents the lowest investment cost, but the starting demand is high. With the second system the demand peak is reduced about 15 per cent, while with the motor-generator set the demand peak is cut to one-half or one-third that of the induction motor, but the cost of equipment is about two and one-half times as much. As the energy consumed per ton of coal by the induction motor is always the same for the same installation, this system is more efficient when the output of the mine is cut down by slumps, car shortage, etc. With the motor-generator set the energy consumed is variable, depending on the rate of use.

Graham Bright of the Westinghouse Company declared that the cost of power should not be considered as very important when selecting drives. He claimed that with flywheel equipment the starting demand should be cut down a great deal more than the paper indicated. An animated discussion arose in regard to buying power from central stations as against private plants. Mr. Bright pointed out that usually water conditions made the private plant out of the question. G. W. Quentin of the Duquesne Light Company said that his company usually supplied mines from two separate sources and sometimes three. He recited a case where one mine supplied with central-station energy suffered a total interruption of only six minutes in one year and defied the advocates of the private plants to compete with this figure. H. Goodwin, Jr., of the Sanderson & Porter Company, told of a very large company with plants in several cities which bought all of its power. This company's opinion, based on actual experience, was that it was far more efficient to buy power because in a private plant the costs usually go up with age while with a central station the costs go down.

L. C. Mosley of the General Electric Company thought that the Ward Leonard equipment gives the most accurate speed control of mine hoists. He also showed how the drum shape of a hoist motor was a very important factor to contend with. This problem, he asserted, lends itself to a definite mathematical solution.

## A. I. E. E. Summer Meeting

**Engineering Progress to Be Celebrated in Diversified Papers at Swampscott Convention**

NEW ENGLAND'S latchstring will hang outside the door for the American Institute of Electrical Engineers from June 25 to June 29, when the annual summer convention will be held at the New Ocean House, Swampscott, Mass., about 15 miles from Boston and on the famous North Shore of the Bay State. The local convention committee has been very active in its preparations and has organized an attractive program of work and play for visiting delegates and guests. Papers of large significance on both theoretical and practical phases of electrical activity will be presented. Local industrial plants, educational institutions and utilities are anticipating visits from the delegates, and trips to the numerous historic and scenic attractions of eastern Massachusetts will be made. There will be also an attractive program of sports. Headquarters will be at the New Ocean House, through which all reservations for accommodations should be made.

The keynote of the convention will be advances in equipment and plant design. Among the subjects to be covered will be modern developments in rectifiers, researches into the nature of insulation failures, artificial transmission lines, electric plants for commercial radio transmission and distribution, a new type of lightning arrester, lamp quality and street lighting, and a whole session will be devoted to the important subject of station economics as affected by the proposed use of 1,200-lb. steam pressure at the new Weymouth station of the Edison Electric Illuminating Company of Boston and by new methods of conducting away heat losses in generating machinery. Electric welding will be considered, and other papers which may be included in the schedule bear upon heat balance and plant economy, duplication of electrical equipment, instrument specifications and electrical instruments. At least one paper is planned expanding the ideas upon engineering education expressed at the Niagara Falls convention of the Institute in 1922.

In the main the afternoons will be devoted to the social and recreational sides of the convention, but if the program is crowded, one or two afternoon sessions may be held, as well as parallel sessions in the mornings.

## Stock Issues Prominent in April Financing

NEW financing in April by electric light and power companies was less vigorous than in March, but exceeded the total reached in April, 1922, by more than twenty-two million dollars. Attention is called to the prominent part taken by preferred-stock issues, they totaling $11,643,800 out of the month's total of $65,718,800. Although long-term securities continued to predominate, several short-term offerings appeared during April. The rate of return yielded the investor advanced to 6.38, and the largest single issue was the thirty-million-dollar offering of gold bonds of the Illinois Power & Light Corporation. Refunding was less active.

SECURITY ISSUES OF ELECTRIC SERVICE COMPANIES IN APRIL

| Name of Company | Amount of Issue | Period, Years | Class | Purpose | Interest Rate | Price | Per Cent Yield |
|---|---|---|---|---|---|---|---|
| Illinois Power & Light Corp. | $30,000,000 | 30 | First and refunding mortgage gold bonds, series A | Refunding and to provide working capital | 6 | 98½ | 6.10 |
| Houghton County Electric Light Co. (Mich.) | 225,000 | 4 | First mortgage bonds | Refunding and to reduce floating debt | 5 | 95 | 6.35 |
| San Gorgonia Power Co. (Cal.) | 400,000 | 1–24* | First mortgage serial gold bonds | Capital expenditures | 7 | 100 | 7 |
| Dominion Power & Transmission Co., Ltd. (Ont.) | †400,000 | 9 | Gold bonds | Extensions | 5 | 91½ | 6 |
| Public Service Electric Power Co. (N. J.) | 14,000,000 | 25 | First mortgage sinking-fund gold bonds | Additions | 6 | 97½ | 6.20 |
| | 6,000,000 | .... | Cumulative preferred stock | Construction | 7 | 98¾ | 7.10 |
| Portland Railway Light & Power Co. (Ore.) | 2,000,000 | 24 | First lien and refunding mortgage gold bonds, series B | Construction | 6 | 94½ | 6.45 |
| Central Maine Power Co. | 600,000 | 3 | Gold coupon notes | To reduce floating debt and for other purposes | 6 | 99 | 6.38 |
| Houston Lighting & Power Co. (Tex.) | 2,000,000 | 30 | First and refunding mortgage gold bonds, series A | To reimburse for expenditures and for other purposes | 5 | 89½ | 5.75 |
| Iowa Southern Utilities Co. | 1,000,000 | 20 | First and refunding mortgage gold bonds, series 1923 | To reimburse for improvements and for other purposes | 6 | 93 | 6.63 |
| Sierra Pacific Electric Co. (Nev.) | 1,643,800 | .... | Cumulative preferred stock | General corporate purposes | 6 | 80 | 7.50 |
| West Penn Power Co. | 500,000 | .... | Cumulative preferred stock | Additions | 7 | (ex. div.) 100 | 7 |
| Indiana Power Co. | 1,000,000 | .... | Cumulative participating preferred stock | Additions | 7 | 89 | 7.87 |
| Long Island Lighting Co. | 1,000,000 | .... | Cumulative preferred stock | Reimburse for expenditures | 7 | 100 | 7 |
| Middle West Power Co. (Ill.) | 3,850,000 | 20 | First mortgage gold bonds, series A | Reimburse for expenditures and for additions | 6½ | 97¼ | 6.75 |
| Toledo Edison Co. | 1,500,000 | .... | Preference stock, cumulative series A | Extensions | 7 | 93½ | 7.50 |
| Total | $65,718,800 | | | | | | |

*Due serially Oct. 1, 1924-1947.

†Offered in March; not included in March tabulation.

## Halts Flaming Gorge Plan

**Federal Commission Also Imposes Delay for Flathead Lake—Pit River Permits Issued**

THE determination of the Federal Power Commission not to act on the Girand license applies with equal force to other Colorado River projects. Despite the very urgent plea made by Utah interests and by the state itself, the commission has declined to take action on the preliminary permit asked by the Utah Power & Light Company covering its Flaming Gorge project. The permit is essential to the work of exploring foundations and to the preparation of plans. The demand for power in Utah is growing at such a rate that a delay in the development of Flaming Gorge may make necessary the erection of a steam plant at Salt Lake City, an alternative which is strongly opposed both on account of the higher rates which consumers would have to pay and because of the aggravation of the smoke problem which would follow the erection of a large power plant.

The Flathead Lake power project also is apparently enmeshed in delay and uncertainty comparable with the Colorado River situation. The staff of the commission urged at its April 23 meeting that the Rocky Mountain Power Company should receive a preliminary permit, abundantly safeguarded to protect the interests of the State of Washington, so that it could do the preliminary work necessary to the 270,000-hp. development planned at the outlet of the lake. The commission decided, however, to withhold action until the special commission appointed by the Secretary of the Interior to investigate the Columbia Basin plan should report.

PERMITS FOR PIT RIVER NOS. 3 AND 4

A preliminary permit has been granted by the commission to the Mount Shasta Power Corporation, a subsidiary of the Pacific Gas & Electric Company, covering two projects on the Pit River. The projects are known as No. 3 and No. 4. A license also was authorized in connection with the No. 3 project. The company has completed one project which does not come within the jurisdiction of the federal government. Ultimately it expects to complete five large developments on the river.

The commission has authorized a modification in the license issued the Southern California Edison Company for the project on Big Creek at the headwaters of the San Joaquin River. The company is rearranging its program so as to complete certain units five years earlier than was planned at first. This necessitates the elimination of one reservoir. Instead a diversion dam and an enlarged conduit are to be built to carry flood waters into another reservoir.

A license has been granted to the Molybdenum Corporation of America for the development of a small project on the Red River in New Mexico. The power is to be used for mining purposes.

Application has been made by the Knoxville Power & Light Company, an Electric Bond & Share Company property, for a preliminary permit covering the development of 200,000 hp. at four sites on the Clinch River. The application is in conflict with one from the Tennessee Hydro-Electric Company.

Additional time has been granted to the Niagara Falls Power Company for the installation of its new units, the commission having agreed to extend the time from May 1 to Dec. 31 for the installation of one of these units, while the date for the installation of the other two has been extended from March 1, 1924, to Sept. 1 of that year.

## Water-Power Applications on Pacific Coast

Six applications for permits to appropriate water for power purposes were received by the Department of Public Works of the State of California during the month of March. The largest of the applications is that of Ray L. Allin, Sacramento, whose petition asks for a permit to appropriate 1,625 second-feet and 1,365,000 acre-feet per annum from Clear Lake and the North Fork of Cache Creek, all in Lake County. Mr. Allin proposes to develop 228,000 hp. and will construct 21 miles of conduit and 16 miles of pipe lines.

The Modesto Irrigation District has applied for a permit to appropriate 1,500 second-feet and 150,000 acre-feet per annum from the Tuolumne River in Stanislaus County. The district purposes to develop 17,000 hp. at an estimated cost of $360,000. The other applications are for small projects affecting only local areas.

During March the Division of Water Rights of the department issued three permits for the appropriation of water for power purposes. Roy H. Elliott, Hobart Building, San Francisco, has obtained a permit to appropriate 10,000 acre-feet per year from the North Yuba River in Yuba County. Mr. Elliott purposes to develop 20,682 hp. at an estimated cost of $1,500,000.

The Washington State Hydraulics Division recently received an application from Sterling B. Hill for a permit to divert 1,000 second-feet of water from the South Fork of the Nooksack River. Mr. Hill contemplates the erection of a large hydro-electric power plant and intends to spend in the neighborhood of $2,000,000. Mr. Hill has also made application for permission to divert 200 second-feet from Whatcom Creek, where he plans to erect a four-hundred-thousand-dollar hydro-electric plant. In addition to this the applicant intends to develop storage amounting to 65,000 acre-feet in Lake Whatcom. This water will also be used for power-generating purposes.

The Douglas Light & Power Company of Roseburg, Ore., has made application to the State of Oregon for a permit to appropriate 595 second-feet of water from the North Umqua River. The application asks for this amount of water for power purposes in addition to the 705 second-feet granted to the company under an old permit. The company plans to develop 2,289 hp. for light and power service in the adjacent territory.

## Maryland Utility Merger Plans Are Announced

Plans are nearing completion for the formation of the Maryland Public Service Company, a new subsidiary of the American Water Works & Electric Company, which is to include the Potomac Public Service Company and the Cumberland Edison Company, both now controlled by the American company.

The plan calls for the issue of $3,893,000 of 6½ per cent bonds, of which $1,275,000 will be used to retire the outstanding bonds of the Cumberland Edison Company. The rest will be used in repayment of advances for new construction and other purposes by the American Water Works Company.

The rest of the capitalization of the Maryland Public Service Company will consist of $514,300 of 7 per cent preferred stock, which will be exchanged for a like amount of Cumberland Edison stock, and 25,000 shares of no-par-value common stock to be held by the parent company. A public hearing on the merger plans and finances will be held in Baltimore before the Maryland Public Service Commission.

## Indiana Electric Utilities to Spend $50,000,000

New development work projected for this year or already under way by the electric light and power utility companies of Indiana will, it is estimated, entail an expenditure of $50,000,000, and the work planned, when completed, will place Indiana in the front rank of the states enjoying high-class utility service, according to Harry Reid of Indianapolis, president of the Indiana Electric Light Association and head of the Great Lakes Geographic Division of the National Electric Light Association, who added in a recent interview: "Indiana already has an investment of about $200 per capita in the public utility industry, which is about $40 per capita above the general state average."

Property additions, extensions of service, construction of transmission lines, building of power houses, connection of large populated areas, displacement of antiquated electrical equipment and expansion of generating facilities all form part of the year's new developments by Indiana light and power utilities. A large amount of this work centers in the Indianapolis area, although extensive construction programs are to be carried to completion in other of the larger cities of the state. Improvements and additions by the Indianapolis Light & Heat Company, planned prior to the explosion in the Mill Street plant two or three weeks ago, with the Terre Haute, Indianapolis & Eastern project and the Terre Haute

power development of the Central Indiana Power Company, are indicative of the general development of the electric power business, Mr. Reid said.

## California Railroad Commission On Valuations

Figures showing the reductions made by the California Railroad Commission in the valuations of public utilities for rate-making purposes as compared with the valuations submitted by the utilities themselves, with a corresponding saving in rates to the people of the state, have been submitted by President Clyde L. Seavey of the commission to the Legislature.

Reductions in the valuations of ten railroads and street railways, eight water companies, the Pacific Gas & Electric Company, the Southern Sierras Power Company, the Holton Power Company, the Western States Gas & Electric Company and the Great Western Power Company alone amounted to $128,922,688, with a corresponding saving in rates to the public of $10,227,000, according to the figures taken from the books of the commission. If rates as a whole had been augmented by even so slight an amount as 1 per cent, it would have added the sum of $4,000,000 to the amount paid by the ratepayers, the commission claims.

In the case of the Pacific Gas & Electric Company, the commission reports, the company claimed a valuation of $170,711,271 and the commission established a value of $109,723,695, a reduction of $60,987,576 and a saving to the ratepayers in one year of $4,800,000; in the case of the Southern Sierras Power Company and the Holton Power Company the companies claimed a valuation of $27,571,271 and the commission established a value of $14,026,126, a reduction of $13,545,145 and a saving to the ratepayers in one year of $1,080,000; in the case of the Western States Gas & Electric Company the company claimed a valuation of $8,793,063 and the commission established a value of $8,393,063, a reduction of $400,000 and a saving to the ratepayers in one year of $32,000, and in the case of the Great Western Power Company the company claimed a valuation of $69,516,725 and the commission established a value of $38,873,479, a reduction of $30,643,246 and a saving to the ratepayers in one year of $2,450,000.

The comparison between the transactions of the Railroad Commission in 1915 and in 1922 shows an increase of nearly 80 per cent. In 1915 the expenditures of the commission aggregated $349,235, while in 1922 they totaled $488,595, an increase of but 40 per cent. It is the object of the report submitted to the Legislature by President Seavey, he says, to place the facts clearly before that body so that the commission may be adequately provided with the funds necessary to continue its service to the people of California.

# Brief News Notes

**Introducing Electricity to the Pharaohs.**—Recent explorations in Egyptian tombs render timely this view of the oldest room in the world which contains a generating plant. It is the entrance chamber of the tomb of one of the Pharaohs who ruled the Egyptians between 1200 and 1100 B. C., and is near Luxor, the ancient Thebes. C. J. Hamilton, who has recently become sales manager, for the Buffalo office of the Vacuum Oil Company, was for three years sales manager for that company in Egypt. Mr. Hamilton tells of a visit to this plant, which consists of a

British-built generator and an internal combustion engine and is used for lighting the various tombs of the ancient kings of Egypt which have been opened. It will probably supply electricity for the tomb of Tut-ankh-Amen next fall when it is opened for public inspection. A native engineer has charge of the outfit.

**Arkansas Central Power Company Takes Over Little Rock Utility.**—The Little Rock Railway & Electric Company has been absorbed by the Arkansas Central Power Company, just incorporated under the "no-par-value" act of the recent Legislature. Operation will continue under the same management. H. C. Abell of New York was elected chairman of the board of directors.

**Chippewa May Take Over Central-Station Distributing System.**—As a means of reducing light and power expenses both to the city and to individual consumers the City Commission of Chippewa, Wis., has under consideration the advisability of taking over the local electric distributing system of the Wisconsin-Minnesota Light & Power Company. At present the city cannot distribute electricity to private consumers. If the company will not consent to sell the plant to the city, it is said to be the plan of the municipality to institute condemnation proceedings.

**Los Angeles Council Favors Survey of Utility with View to Condemnation Proceedings.**—Following a bitter fight in the City Council of Los Angeles, an ordinance was passed recently authorizing an appropriation for a survey to fix the price of the electric distributing system of the Los Angeles Gas & Electric Corporation. The survey is being made by the California Railroad Commission for the purpose of clearing the way to start condemnation proceedings to acquire the property. Recently when the city ordered the survey the company commenced a suit on the ground that the commission had no authorization to spend money for that purpose.

**Interstate Buys Four More Plants.**—Officials of the Interstate Public Service Company of Indianapolis announced recently that the company had bought the properties and franchises of the Jeffersonville Water, Light & Heat Company and the plants at Francisville, Monon and Medaryville in Indiana. The company paid $250,000 for the Jeffersonville property and $90,000 for the other plants. It already owned the utilities in New Albany, a few miles from Jeffersonville. Energy for light and power for Francisville, Monon and Medaryville will be supplied by the plant of the Indiana Hydro-Electric Company near Monticello, which will be operated by the Interstate Company.

**Insull Companies Buy More Coal Land.** — The Commonwealth Edison Company of Chicago and the Public Service Company of Northern Illinois will be further protected in their coal supply by the organization of the Industrial Coal Company, which has acquired 6,200 acres of valuable coal lands in Franklin County, Ill., and two modern well-equipped mines already in operation. These coal properties will augment mines already owned by these companies. The Edison company will receive one-third of the output of the new company's mines and the Public Service company one-sixth. The Peabody Coal Company will rceive one-half of the output.

**Providence Utility Company Increases Facilities.**—Dwight P. Robinson & Company, Inc., engineers and constructors, New York, have started work on the design and construction of the complete new switching plant which, as already announced, is to replace and extend the present facilities of the Narragansett Electric Lighting Company of Providence. The work includes a new four-story brick and concrete building and a smaller three-story extension to the present switch house. All power will be distributed from the new switching station to substations at 11,000 volts and 22,000 volts. In order to provide for future expansion all equipment will be designed for 22,000 volts.

**Westinghouse War Memorial Scholarships.** — The Westinghouse Electric & Manufacturing Company has announced that applications can be filed for its 1923 war memorial scholarships, open to employees of two years' continuous standing and not more than twenty-three years of age and to sons of

employees of five years' standing. Four scholarships are established annually by this company as a memorial to employees who served in the world war. Each scholarship carries with it an annual payment of $500 for a period not to exceed four years, such payment to be applied toward an engineering education in any technical school or college that the successful candidate may select with the approval of the committee.

**New Water Power in Quebec.**—Contracts for two important new water-power developments in the Province of Quebec have recently been let, says Consul E. H. Dennison in a report to the Department of Commerce, one of these being in connection with the rapids of the Grande Décharge of Lake St. John, while the other is a 15,000-hp. development on the Outarde River, on the north shore of the coast of that lake. It is predicted that within five years a minimum of 230,000 hp. will be developed at a cost of $12,000,000. There are said to be possibilities for developing 1,000,000 hp. from the stretch of rapids extending from Lake St. John to the head of navigation of the Saguenay.

**Hearing on Revaluation of Alabama Power Company Under Way.**—Revaluation of the properties of the Alabama Power Company, a matter which has been a football in Alabama politics for the last year, is provided for in an order issued recently by the Alabama Public Service Commission, and hearings started before the commission at Montgomery on May 1. The order for the revaluation is issued under the provisions of an act passed last February by the Legislature which authorized the commission to revalue public utilities in the state upon which valuations have already been fixed within three months after the approval of the act. The valuation made by the old commission, which went out of office in December, was attacked as too high and thereby permitting excessive rates to consumers.

**Electric Vehicle Schools for Salesmen.**—Under the direction of the Electric Truck and Car Bureau, supervised by the education committee of the Commercial National Section, N. E. L. A., two electric vehicle schools for salesmen are to be held in May and June—one in New York from May 15 to May 26 in the New York Edison Company building and the other in Chicago from June 19 to June 30 in the Commonwealth Edison Company building. The course of instruction will include transportation, engineering, trucks, motive equipment, batteries, garage equipment and operation, and truck operating and maintenance. The students will consist of representatives of electric light and power companies. Each school will be limited to fifty students, made up from the first fifty applications received. Only one application will be accepted from each company if a sufficient number from other companies apply to fill the class. There will be no charge for tuition. Applications should be made at once to E. S. Mansfield, chairman electric vehicle school committee, 39 Boylston Street, Boston.

**Fayetteville to Have New Central Station.** — A new power station for Fayetteville, N. C., to be constructed at a cost of approximately $750,000, has been announced by the Carolina Power & Light Company. The company has purchased 50 acres of land near a large manufacturing plant, and it is planned to erect the power station there. The power will be supplied from the Blewitt's Fall, Wateree and Yadkin River generating stations. To be used in cases of emergency, the company is also constructing a plant near Moncure, on Cape Fear River. This plant will supply cities in this territory with power in time of low water. More than a half million dollars has already been invested in the Fayetteville enterprise, according to a company representative. Work on the plant there will be started at once, and the company will be able to furnish the increased supply of energy immediately on the completion of the station and of a steel-tower line now being built from Laurinburg.

# Associations and Societies

**Electrical Supply Jobbers.**—The regular quarterly meeting of the Pacific Division, Electrical Supply Jobbers' Association, will be held at the Hotel Del Monte, Del Monte, Cal., on May 10, 11 and 12.

**National Association of Manufacturers.**—Some of the pressing subjects to be discussed at the convention of this association in New York on May 14-16 are transportation, construction, production, the open shop, immigration, taxation and the merchant marine.

**Chamber of Commerce to Take up Coal Problem.**—A plea for solution of of the coal problem by economic rather than legislative means will mark the session of the natural resources group at the eleventh annual meeting of the Chamber of Commerce of the United States, to be held in New York on May 7-10. The group will devote its time to coal entirely.

**Southwestern Public Service Association.**—The nineteenth annual convention of this association, to be held at the Texas Hotel, Fort Worth, on May 15-17, will bring together for the first time in several years all the utilities in the Southwest. Among the speakers expected from outside the state are H. C. Abell of New York, chairman of the committee on public utility information bureaus, N. E. L. A.; Labert St. Clair of New York, W. H. Sawyer of St. Louis, H. T. Edgar of Boston and Oscar Fogg of New York. Special entertainment features have been provided.

**Salt Lake Engineers Gather.**—At the regular weekly "All Engineers" luncheon held at the Salt Lake City Chamber of Commerce on April 9 R. A. Hart, drainage engineer of the Department of Agriculture, who has recently returned from a trip to Hawaii, said that electrically operated pumps are rapidly replacing the old apparatus used for pumping in the irrigated districts of that territory, which comprise 80 per cent of the agricultural land. These weekly luncheons, held every Monday, are well attended, bringing the engineering fraternity of the city together.

**Missouri Association Planning Program.**—For the seventeenth annual convention of the Missouri Association of Public Utilities, which will be held on the steamer Harry G. Drees from May 24 to 26, sailing up the Mississippi and Illinois Rivers from St. Louis to Peoria and return, with frequent stops, a good program of papers and addresses is being arranged. The entertainment features will comprise dancing and golf on courses adjacent to the river. Since the boat will accommodate not more than 200 persons, reservations should be made as soon as possible with F. W. Beardslee, 721 Locust Street, St. Louis.

## Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

Nebraska Section, N. E. L. A.—Omaha, May 10-11. Horace M. Davis, Lincoln.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

Empire State Gas and Electric Association, Electric Section—Utica, N. Y., May 17-18. C. H. B. Chapin, Grand Central Terminal, New York.

Electrical Supply Jobbers' Association—Executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

Missouri Association of Public Utilities—River boat from St. Louis to Peoria, May 24-26.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

California State Association of Electrical Contractors and Dealers—Dorner Lake, Cal., June 9-16.

Electric Power Club — Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

North Central Division, N. E. L. A.—Minneapolis, June 13-15. H. E. Young, Minneapolis General Electric Company.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

Iowa Section, N. E. L. A. — Mason City, June 20-22.

Society for the Promotion of Engineering Education—Ithaca, N. Y., June 20-22. F. L. Bishop, University of Pittsburgh.

Canadian Electrical Association — Montreal, June 20-23. Louis Kon, 65 McGill College Ave., Montreal.

American Institute of Electrical Engineers—Annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

American Society for Testing Materials—Atlantic City, June 25-29.

Associated Manufacturers of Electrical Supplies—New London, Conn., June 26-29. Frederic Nicholas, 30 East 42d St., New York.

National Council Lighting Fixture Manufacturers—Buffalo, June 26-28. C. H. Hofrichter, 233 Gordon Square Bldg., Cleveland.

Northwest Electric Light and Power Association—Seattle, June 27-30. G. E. Quinan, 204 Electric Bldg., Seattle.

Ohio Electric Light Association — Cedar Point, July 10-13. D. L. Gaskill, Greenville.

New England Division, N. E. L. A.—Swampscott, Mass., Sept. 6-8. Miss O. A. Bursiel, 149 Tremont St., Boston.

## Recent Court Decisions

**Interpretation of Utah's Watercourse Laws.**—An attempted interpretation (in Caldwell vs. Erickson) of the phraseology referring to the authority of the State Engineer, "He shall have general administrative jurisdiction of the waters of the state," to mean waters owned by the state was overruled by the Utah Supreme Court, which held "of the state" in this instance clearly to mean the same as "in the state." (213 Pac. 182.)*

**Telephone Company Liable for Damages Caused by Contact of Its Lines with Electric Light Wires.**—Damages for loss from fire were confirmed against the Two States Telephone Company (plaintiff Hurley) by the Court of Civil Appeals of Texas, the court finding the company responsible because of the careless construction of its lines, which passed under the wires of the electric light company close to the building where the fire occurred and, it was alleged, came into contact with them, causing the fire. (248 S. W. 424.)

**Burden of Proof on Party Claiming Right to Raise Dam.**—Davenport vs. Centerville Water & Electric Company was a suit by landowners to enjoin the owner of a dam from raising water to a greater height than that to which it was raised by a former dam. The burden of proof was, the Supreme Court of Michigan held, on plaintiffs to establish by a preponderance of evidence that the crest of the dam, as limited by a decree of the trial court, was higher than that of the former dam. This evidence the Supreme Court did not find to be forthcoming. It added that a court may take judicial notice of wet and dry seasons which would affect the amount of water on lowlands. (192 N. W. 705.)

**Damages Refused Because of Failure of Electric Service Company to Provide Surplus Water for Irrigation.**—In Gause vs. Pacific Gas & Electric Company damages were sought because of the defendant's alleged failure to deliver water for irrigation purposes according to contract. In affirming judgment for the defendant, the California District Court of Appeal said: "The allegation of the breach of the water contract is insufficient. It is apparent that therein respondent agreed to furnish water upon certain conditions. It was expressly stipulated that it should first be used for the generation of electrical energy, which was declared to be its primary purpose. In fact, the fair interpretation of the covenants of the parties is that the company would furnish water if it had any left or was able to do so after using what was necessary for the development of the requisite electrical energy. That circumstance or contingency therefore became an inseparable part of the promise, and in order to state a cause of action it would be necessary to show that such water was not needed for that purpose. In view of the absence of any allegation to that effect, it will be presumed that respondent discontinued the delivery of the water for the reason that, in the opinion of its engineer, it was necessary to conserve it for the development of electric power." (212 Pac. 922.)

**Failure to Warn Carpenter of Possible Danger from Escaping Currents Is Negligence.**—In Jordan vs. Malden Electric Company damages were claimed because of the death of a carpenter who ascended to the roof of an electric power plant in company with the resident engineer and the foreman of the meter department to estimate on the work of building a projected platform, being plainly therefore lawfully upon the premises. The testimony tended to establish that he had not touched any of the equipment or wires, against doing which he had been warned, but had been killed by an arc-over from a lightning arrester near which he had been allowed to go. The Supreme Judicial Court of Massachusetts held that it could not be assumed as a matter of law that the victim knew or should have known of the peril in approaching the arrester and sustained the verdict for the plaintiff rendered in the trial court. (138 N. E. 536.)

**Regulation of Sale of Power Imported from Another State.**—In dismissing as "fragmentary and premature" an appeal of the Cannon Manufacturing Company and other cotton-mill operators against rates fixed by the North Carolina Corporation Commission for the Southern Power Company and remanding the case to the county court (see ELECTRICAL WORLD, March 3, page 533), the Supreme Court of North Carolina made observations to the following purport on the regulation of the sale of power imported from another state: Though the transportation into the state and sale of electrical energy therein directly to purchasers is interstate commerce, the regulation of the sale, including the fixing of rates at which it can be sold, is a matter within the power of the state where the sale is made, in the absence of any regulation by Congress. Evidence that a public utility whose rates were fixed by the Corporation Commission had made contracts with consumers in another state not affected by the decision, but that those contracts were made when the utility was first developing its plant and were less than the rates fixed by the commission within the state chiefly because the consumers thereunder took more power than those within the state, and that later contracts were at rates equal to those fixed by the commission, did not show that the rates fixed by the commission were unjust in contrast with the contract rates. (116 S. E. 178.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

## Commission Rulings

**Flat Rates Obsolete—Street Lighting Service.**—In authorizing new rates for the Fort Bragg Electric Company, the California Railroad Commission condemned flat rates as obsolete even in a small community and indorsed the meter rates which the company proposed to substitute. An electric utility, it said also, should own the entire street-lighting system except lamps and globes, which may be owned and maintained by the consumers. Rates for street lighting should be fixed on the basis of a fixed monthly charge varying with the size of lamp and number of annual burning hours.

**Company Ordered to Serve Customers of Municipal Plant.** — The Wisconsin Railroad Commission, on rehearing at the instance of the Lincoln Light Company, affirmed a previous order compelling that company to serve three extraterritorial customers of the Manitowoc municipal plant who, at the commission's instance, had been connected to the Lincoln Light Company's lines by the city, the line over which the city originally served them having been removed by a private individual who owned it. Under the commission's order the three customers thus served paid the legal rates to the city plus a rental charge of $6 a year each, and this revenue was turned over by the city to the company. The three customers were thus saved the expense of paying for connection. The company asked that these customers be placed upon the same footing as the other consumers whom it serves. (See ELECTRICAL WORLD, Sept. 23, 1922, page 683.)

**Unprofitable Rural Extensions**—A petition for an extension of electric service was denied by the Maine Public Utilities Commission in a case affecting the Cumberland County Power & Light Company on the ground that the extraordinary cost of rendering the service was so great and the resulting deficit would be so large that the company should not be required to make the extension without a guarantee of revenue approximating the cost of rendering the service. In the case at issue this was declared to be impracticable. The commission reiterated its view formerly expressed that rural service ought to be required whenever it can be given without placing an undue burden either on the company or on its other customers, even though the service must be rendered without profit; but it added: "If any particular section of the community is so situated by reason of its distance from the distribution line, its sparsely settled territory or any other reason that service to such community can be rendered only at additional or extraordinary cost, such additional or extraordinary cost must be borne by the particular community desiring the service."

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

### Dr. Albert Hull Honored

Dr. Albert W. Hull, scientist in the research laboratory of the General Electric Company, has been awarded the Howard N. Potts gold medal for scientific research by the Franklin Institute, Philadelphia. The award was made for his studies in the crystalline structure of matter by means of X-rays and was based on a paper entitled "Crystal Structures of Common Elements" read before the Franklin Institute last year. Dr. Hull is also one of the foremost authorities on electron vacuum tubes and has been responsible for the development of some of the latest and most interesting types, such as the dynatron and magnetron, including a million-watt power tube. He has been active in the development of radio apparatus and last summer delivered a special course of lectures on X-rays and vacuum tubes at Columbia University.

The Potts medal was established in 1906 from a trust fund left by the will of H. N. Potts of Philadelphia. It is awarded only for "distinguished work in science or the mechanic arts."

### Ferguson Heads New England N. E. L. A. Division

Samuel Ferguson, vice-president of the Hartford (Conn.) Electric Light Company, was elected president of the New England Divison of the National Electric Light Association last week at the annual meeting of the organization at Providence, R. I. Mr. Ferguson is a nationally known central-station executive and has been vice-president of the Hartford company for eleven years. For twelve years previous to his association with the Hartford Electric Light Company he was connected with the research laboratories of the General Electric Company at Schenectady. Mr. Ferguson was born in Exeter, N. H., in 1874 and is a graduate of Trinity College, Hartford. Other officers chosen were: Fred H. Smith, Worcester, Mass., vice-president; Miss O. A. Bursiel, Boston, Mass., secretary; G. M. Guilford, Boston, treasurer. The new officers will take up their work after the annual convention of the division at Swampscott, Mass., Sept. 6-8.

### E. W. Rockafellow Joins National Pole Company

E. W. Rockafellow, known to all the industry as one of the elder statesmen of the electrical jobbing fraternity, has resigned from the Western Electric Company to become a vice-president of the National Pole Company in charge of sales. Mr. Rockafellow has been identified with the Western Electric Company since the very early days of the electrical industry, having grown up from office boy with that organization, and for many years he has borne the title of general supply sales manager. He has long been a prominent member of the Electrical Supply Jobbers' Association, and it will be exceedingly hard for electrical men to think of him as other than a jobber. As the Western Electric Company has been the principal distributor of the National Pole Company Mr. Rockafellow has long been in intimate association with the pole field, and he enters upon his new responsibilities with all the background of a pole man. He will have his office at 220 Broadway, New York.

### A. B. West Receives Promotion

A. B. West, vice-president and general manager of the Southern Sierras Power Company and the Nevada California Electric Company, has been named president of the Southern Sierras Power Company, to succeed the late Guilford S. Wood of Denver. After his graduation from Stanford University in 1899 Mr. West became junior member of the law firm of Potter & West in Denver. At that time this firm was acting as general counsel for the Nevada-California Power Company, and when the power company decided to enter the southern California field Mr. West was transferred to the operating end of the business and made vice-president and assistant to the president. During his association with the company it has experienced a remarkable growth and has been an important factor in the development of the southern part of California. He has been active in the Pacific Coast Electrical Association, having at one time served as its president. Fred O. Dolson, general superintendent, and E. B. Criddle, general agent, of the Southern Sierras Power Company were made vice-presidents of the company at the time of Mr. West's election to the presidency.

A. B. West

Th. G. Holmboe, editor *Teknisk Ukeblad*, Christiania, Norway, is in the United States on an eight weeks' visit, studying American engineering practice.

## Obituary

**Floyd Charles Furlow**, president of the Otis Elevator Company, died on April 26 at the Ritz-Carlton Hotel, New York, after an illness of six weeks. Mr. Furlow was educated at the Georgia Institute of Technology and later, while pursuing the profession of consulting engineer at Atlanta, lectured in experimental engineering there. He became chief engineer for the Otis Elevator Company in 1905, and soon after was made vice-president and then president. Mr. Furlow, in spite of his business activity, did extensive research work in electrical, hydraulic, and steam engineering and machine design.

**Frank E. Russell**, general manager of the Tucson (Ariz.) Gas, Electric Light & Power Company, died at his home in that city on April 15, at the age of sixty years. Mr. Russell suffered a breakdown in health in July, 1922, being taken with a severe attack of sciatic rheumatism, which finally developed into pneumonia, from which a complication of diseases resulted. Mr. Russell began his public utility career with the Western Union Telegraph Company, subsequently becoming active in the organization of the Tucson Gas, Electric Light & Power Company during the year 1892. Shortly after this he was appointed general manager, and he continued in that office until his death, a period of more than thirty-one years. In 1910 the Tucson company became a unit of the Federal Light & Traction Company of New York.

**Eugene Carpenter**, a pioneer New England central-station man, died on April 25 at the age of fifty-five. Mr. Carpenter was a native of Rowe, Mass., and among his earlier activities was the building of the central station at Gardner, Mass., and the pioneer three-phase hydro-electric installation for transmission of energy from Sewall's Falls to Concord, N. H. After engaging in construction work and subsequently in selling he became interested in the central-station properties on Martha's Vineyard and Cape Cod, developing these under the organization of the Boston Electric Associates, which also built up a number of small utility plants in the interior of Massachusetts and New Hampshire. Under Mr. Carpenter's guidance the Cape and Vineyard properties flourished, and to him more than to any other is due the development of electrical service in the sparsely settled area east and south of the Cape Cod Canal. He was active in the New England division of the N. E. L. A. and contributed much to its convention discussions.

# Manufacturing and Markets

Devoted to the Discussion of Business and Economic Problems of the Producer and Distributor, with Market Reports, Trade Activities, Foreign and Construction News

## Our Appliance Market—What It Needs *

### Sales Now Falling Behind Increase in Houses Connected—Four Fundamentals That Must Be Organized Into Our Selling

By Martin L. Pierce
Research and Promotion Manager Hoover Suction Sweeper Company
North Canton, Ohio

We have in the United States today approximately 8,500,000 homes wired for electricity. The normal increase of resident meters is 12½ per cent per year. During the investigations which I have made in the last few months I have not found a single community in which there are as many home demonstrations being made week by week for the three major appliances—washers, ironers and sweepers—as there are new home meters being connected. Of course, there may be such communities, but in my investigation I have failed to find one. In many of the larger cities, such as Cleveland, Ohio, I found that the home demonstrations did not equal more than 50 per cent of the new homes being electrified.

In other words, the merchandising of appliances is running approximately 50 per cent behind the electric development. The time has come when the electrical industry should establish for itself a definite sales responsibility for electric appliances.

#### What the Market Is

The electrical industry has been too modest in the past, both in its demands and in its expectation regarding the average investment of the typical home owner. While the plumber has been getting from 13 per cent to 15 per cent of the cost price of the average home or apartment, the electrical dealer has, for the most part, been satisfied to get from 1 per cent to 3 per cent. There is certainly no reason, however, why the electric industry should not be obtaining from the home owner an investment for electrical equipment that will at least equal that obtained by the plumber.

*From a paper read before the convention of the Southwestern Geographic Division, N. E. L. A., Oklahoma City, March 14-16, 1923.

The electrical industry in California, after a very thorough analysis, has come to the conclusion that every household should spend as much for electrical equipment as it spends for its automobile. The industry feels that the time has come for the installation of complete electrical equipment, and it is making a concerted drive for the realization of that end.

Recent investigation showed that for every ten wired homes in the United States there are nine automobiles, there are nine talking machines, but there are only one and a half electric cleaners and only one electric washing machine. Shall we not establish for ourselves a program that will comprehend the selling of as many of the major appliances as there are automobiles and talking machines in any given community?

#### Turnover Means Profit

To reach this possible market for electrical appliances the industry should universally make use of modern merchandising ideas and methods.

Above all else, these four things should be done:

First—The advertising of the industry should be built on facts, not "hunches." For instance, a Western central-station company operating in about thirty towns began a campaign on washing machines. These were advertised extensively in the newspapers. Their basic appeal was that of economy. The campaign did not go over. A washing machine was offered as a prize for the woman who would send in the best reason why a woman should have a washing machine. More than two thousand replies were received, and these are the reasons according to the women themselves: Thirty per cent wanted the machine because it saved time, twenty-five per cent because it saved strength, 14 per cent because it saved health, 12 per cent because it preserved youth and beauty, 8 per cent because it was more economical and 7 per cent because it contributed happiness to the home. The advertising campaign was changed to conform to the information gained from these prospective customers, and sales went over with a bang.

Second—The industry must appreciate the fact also that profit comes from turnover, not mark-up. The merchandising manager faces two kinds of expense, selling expense and carrying charge. In the large dry-goods store and the small department store, for example, the selling expense is 4 per cent and the carrying expense 20 per cent. An upholstered chair that cost $100 and is marked up 50 per cent would sell at $150. If the chair were sold the day it was put on the floor, there would be no expense except for selling, which would be $6. The firm would actually have made $44. If it remains on the floor for a year, it will have charged against it $5.25 for rent, $9 for supervision, $4.50 for advertising, $1.50 for heat and light, $1.80 for delivery, $1.80 for insurance and taxes, $3.75 for general expense and $2.40 for depreciation and bad debts.

If at the end of the year the chair is sold for $150, the firm does not make $44 profit, but $44 less $30, which is 20 per cent of $150, or $14. If the chair should remain in stock for two years and the firm should still sell it for a 50 per cent mark-up, the firm would actually lose $16. The small additional discount secured by buying in large quantities seldom equals the carrying charge that must be subtracted from the gross profit.

#### Standard Costs Needed

Third—Standard costs for doing business must be worked out and adopted if the business is to be established on the high plane of prosperity that must be achieved if the job is to be done. At a recent dinner in Canada I sat between two merchandising managers, each in charge

of an electrical department. One of them told me that the overhead charge against his department is 15 per cent. The other man told me that it was 22 per cent, and yet they were both doing business in the same town and under practically the same conditions. The indications were that possibly neither of them knew what the actual overhead charges should be. If either one did know them, the other was being discriminated against. The facts are that the electrical industry, to be successful in merchandising appliances, must be willing to adopt standard costs of doing business.

The costs of hardware stores, dry goods stores and department stores are no longer experiments. These retail firms are actually making money and some of them accumulating millions in reserve on the store costs that have been adopted. In 1921, 366 department stores doing $600,000,000 worth of business did it on an average gross mark-up of 28 per cent. Their net profit on this volume of business was 1.9 per cent. Millions of profits were accumulated because the stock was turned seven or more times on an average. This 1.9 per cent did not take into account the profit made from cash discounts.

Fourth—Our merchandising drive should be set up for twelve months in the year. There was a time when the electrical industry thought that appliances, such as cleaners, could not be successfully sold except at house-cleaning time.. We have learned, nevertheless, that there is no closed season for the selling of appliances.

A Southern central-station company recently put on a special campaign for electric ranges in the winter and sold more than it had ever sold during the same time in the middle of the summer. There are just as many sales arguments for electric cleaners, table appliances, washing machines and electric ranges for winter as there are for summer use.

Every industry that prospers has an ultimate ideal, an aim that cannot be realized in a year and possibly not in a century. With us it is without question the servantless home made possible through the development and use of public utilities. The appliance industry should plan to enter in 100 per cent to bring about the elimination of housekeeping drudgery in every American home.

# Contractors in Cut-Throat Competition

### Owners of Buildings Under Construction Should Have Some Protection in Inspection—Guiding Cost Statistics Are Greatly Needed

By a Manufacturer

I AM WONDERING whether in all our talk about cut-throat competition among contractors we know just what we mean. Most of us probably have in mind the fact that there are a vast number of "chip-basket contractors" who lack all practical knowledge of the rudiments of business and therefore carry on a destructive strife for jobs among themselves. The contractor must be educated, we say, so that he will do "quality" work for a good price and be prosperous. But, as a matter of fact, I believe that our biggest, most educated contractors are probably practicing the worst cut-throat competition in the whole game.

In my opinion, the most conspicuous cut-throat competition that the business is cursed with today comes from the "silk-stocking," college-bred electrical contractor, who terms himself an "engineering contractor" and claims that he has to practice the cut-throat variety of competition to stay in business. How is it done? There are two ways most popular. Poor-quality materials are substituted for those which are specified. That is one method. The other is to bid down the price of the job and then build it up on extras made possible by changing details in the job to differ from the specifications.

#### Selling Down the Job

I have been disappointed, discouraged and disgusted with some of the owners, and even the architects with whom we have got into touch, who have taken the word of some of these large cut-throat contractors as gospel truth and allowed themselves to accept material that was absolutely not in any way up to the standard of the specifications. There has been an epidemic of substituting the cheapest of material in the cheapest method of installation in the past two years, and we are not over it yet. I remember some time ago an engineer telling us how he had actually "sold" the owner on the idea that his job was worth $12,000, and behold, the job was let to a contractor of standing for $7,800. The engineer himself said, "How can they do it?" I suppose by this time he has found out that they substituted in every line of material and "skinned" the job down in workmanship.

As to the "chip-basket" contractor, nobody has ever given him even the credit of having business ability, and naturally when the owner and architect call him in because his price is 20 to 30 per cent lower than that of other contractors and tell him that their appropriation necessitates cutting the electric work still another 20 or 30 per cent, he takes it for granted that they mean exactly what they say, and he proceeds to "skin" the job some more and still further reduce its value.

#### Inspection Ignores Specifications

The result is that, regardless of what is shown or called for on the plans and specifications for a job, the inspection is not based on it. The inspection ordinance in no way recognizes the architects or owners or the engineer's plans and specifications as the basis of an inspection, but instead calls for the contractor to submit a list of the outlets and lights for which he is wiring. That, of course, means the skinned-down job that he has made his price on, so that he can well afford to do the job well for the outlets and capacities of switches that he figured on, and naturally the inspection will give him a clear bill of health and a wonderfully valuable certificate of inspection, which in no way recognizes the capacity or conditions that were called for under the plans of specifications.

#### Education Needed

Now as to the remedy. In the first place, we must educate the architect and engineer and the owner to recognize that there is a classification of value among contractors just as there is in dry-goods stores or any other line of business; that there are some contractors who have the reputation of being cheap, and there are others that have a reputation for responsibility and good installations. It is not fair to have both of these figure on the same job. If the owner wants a good job, he should get a first-class, reputable con-

tractor. If he wants a cheap job, he should not call on the good contractors, but get a man who puts in cheap work. He should know that the price regulates what he is going to get on the job, and, furthermore, he must understand that the inspection is simply on the work as installed.

### Guiding Statistics Needed

Moreover, the electrical industry could well inform the owner, architect and engineer as to the proper cost of the electric work as compared with the cost of the entire building. Let us tell them what a less-than-average installation should cost, an average installation and a better than average installation, and advertise this broadly so that the owner and architect and the engineer will have something fundamental with which to compare their bids. The "quality" contractor could use it as an argument that the statistics of the industry prove that his bid is within reason for a less-than-average or better-than-average job.

I have followed up the residential wiring in one city for a number of years and know of electrical work in jobs running $15,000 and under that ran only from three-tenths to five-tenths of 1 per cent. Just consider the crime of such an installation! On the other hand, I know that where the contract was let to reliable contractors, it began to run up into 2, 3 and 5 per cent, and we have done a number of jobs that ran as high as 7 and 8 per cent. Of course, these could be classed as better than average.

As a matter of fact, I have been told several times by architects that they have quit trying to figure on what the electrical work will cost, because they know it will always be cheap enough anyway. That's a fine reputation for the electrical business.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

TRADE continues vigorous, with well-sustained volume, although the demand upon jobbers last week was decidedly spotty as regards the geographical distribution of orders. Improved transportation conditions are making it easier for distributors to serve their customers, but in most lines the trend of deliveries out of the factory is toward longer datings after receipt of orders. Little complaint of shortages was heard the first of the week, although it is virtually impossible for jobbers to build up stocks in the face of the present demand.

Few price changes of importance were announced last week, the trend being upward in general with firm maintenance of quotations issued in the latest sheets to sales representatives. The upward pressure of labor toward higher wage levels continues, combined with a distinct scarcity of workers in many lines. Prices of Western red cedar poles, 30 ft. with 8-in. top to 90 ft., increased approximately 10 per cent in the early part of the week.

General business is unabated in volume. Building contracts in New England for the latest reported week totaled $8,858,600 against $12,924,400 a year ago, but the former figure exceeds all other corresponding weeks for twenty years. Rubber, textile, metal-working and paper industries are almost overwhelmed with orders. Central-station new-business departments are taking on extensive additional loads, house wiring is running at "full blast," and electrical apparatus manufacturers are working well up toward plant capacity in most lines. Here and there the reconstruction of distribution lines will be necessary as a result of flood conditions on interior rivers, and important interconnections and plant construction for utilities are keeping engineers and sales forces busy. Large telephone and railroad equipment and reconstruction budgets are announced for this section.

## General Business Shows Continued Gain

IN A review of general business and financial conditions the Federal Reserve Board says further increases in production of basic commodities, wholesale prices, employment, wage rates and wholesale and retail trade took place in March.

The board reported, however, that during the month prior to April 11 a more moderate growth in the demand for credit for member banks in leading cities resulted in an increase of about $48,000,000 in their loans, made largely for commercial purposes, as compared with an increase of $235,000,000 in the preceding month.

"Through withdrawal of funds from investments and a further inflow of gold," the board says, "member banks have been able to meet demands of their customers for increased credit and currency independently of the reserve banks. Consequently, the total volume of Federal Reserve Bank credit, measured by the total earning assets, has remained relatively constant during the last month and, in fact, since the seasonal liquidation at the turn of the year."

Production in basic industries, according to the board's index, increased 4 per cent in March to a level 8 per cent higher than at the 1920 peak and 67 per cent above the low point of 1921.

The output of pig iron, steel ingots, automobiles and crude petroleum and the mill consumption of cotton exceeded all previously reported monthly totals.

Building operations showed a further large expansion and the value of contracts let for residences in March was the highest on record. Railroad freight shipments have been larger every week this year than in the corresponding weeks of the last four years. Car shortage has been reduced to the lowest point since September, chiefly as the result of the addition of new equipment, a decrease in the number of locomotives and cars in bad order and a concerted effort to increase the average loadings.

## Case Involving Right to Exchange Trade Information

ARGUMENTS were presented April 25 and 26 before the United States Supreme Court in the case of the government against the American Linseed Oil Company and others, involving the right of business to exchange trade information through associations or through private bureaus acting as clearing houses for such data. The case is considered to be the most important to all trade associations since the hardwood-lumber case, but it involves different questions from those presented in the latter.

The federal government alleged that by exchanging various forms of information which was distributed as statistics by the Armstrong Bureau of Related Industries the defendant linseed-oil companies created a condition tending to prevent competition in prices of their product. The United States District Court for Northern Illinois, where the suit originally was instituted in 1921, held for the defendants and ordered the suit dismissed, the Government appealing.

In arguing before the Supreme Court, Special Assistant Attorney General James A. Fowler declared that daily and instantaneous price reports were sent the bureau by the linseed-oil members and relayed back to the members by the bureau, charging that each day each member knew the prices quoted by his competitors.

Thomas M. Debevoise appeared as attorney for the American Linseed Oil Company and John Walsh, formerly chief counsel for the Federal Trade Commission, appeared in behalf of the Armstrong bureau and other defendants. They argued that while various statistical information was exchanged through the bureau, there was no restriction of output and no combination or agreement as to price. Prices of the oil followed the flaxseed market, they

argued. The right of business corporations to compile statistics on which to base judgment was upheld, they contended, by the fact that the Department of Commerce gathers and distributes statistics of business.

### Says Promotion Work Is Needed to Get Business in Porto Rico

A MUCH larger volume of electrical equipment could be sold in Porto Rico were American salesmen sent to that island with the idea of doing some promotion work. Porto Rico already is a large customer and knows American electrical goods. The central stations on the island are efficient and progressive. The San Juan Railway, Light & Power Company has made active use of the demonstration idea, but much of the business in electrical equipment simply has gravitated to American markets. Very little effort has been expended by American manufacturers or jobbers in increasing the amount of electrical goods which the country will absorb.

To all intents and purposes Porto Rico is domestic territory. There are no duties on imports from the United States. The rather high internal-revenue taxes which are levied on many articles of luxury have not been applied to electrical accessories. These are observations made by R. A. Lundquist, chief of the electrical equipment division of the Department of Commerce, who has just returned from a visit to the island.

Twenty-three out of the thirty-five sugar centrals on the island are electrified. The present price of sugar is encouraging the owners of the remaining mills to consider electrification.

Additional hydro-electric development is certain to come. To be handled to greatest advantage, however, all of the water powers on the island should feed into a single system. The island is 100 miles long and 35 miles wide. Conditions are ideal for meeting the power requirements of the entire island with energy which is produced hydro-electrically.

### Chicago Business Active with Advancing Prices

BUSINESS in Chicago electrical circles still remains active. The most important announcements this week are an advance in conduit and switches and a reduction in the list price of incandescent lamps. Conduit advanced three points. Service entrance switches, externally operated, three-pole, advanced 2 per cent, two-pole 5 per cent, slate fuse blocks 10 per cent, single-pole slate fuse blocks 4 per cent, type C switches 6 per cent and snap switches have advanced 3 per cent.

There has been an approximate reduction of 10 per cent on the entire line of incandescent lamps, the reduction being from 2 cents to 25 cents per bulb on the entire line. This is the first reduction of the entire line in several years. Pole-line hardware demand is extremely active since numerous large orders have been placed for this material during the week. High-tension-equipment sales still remain up to their previous standard.

The demand for flatirons has been very good, and it is the belief that no increase in price of this commodity will occur for some time, inasmuch as irons are highly competitive. While initial orders are being placed for distributors' requirements of fans, the demand has not yet started on this class of material. Prices are firm. Storage batteries are holding their own, with no increase anticipated at this time.

### Motor Demand Well Sustained; Prices Expected to Increase

TAKING the country as a whole, the demand for motors of moderate size continues active, taxing current manufacturing facilities close to capacity. There is no present sign of a lower volume of business, but in some circles the curve of increased sales is expected to swing toward a smaller angle against time within a few months. In other words, there is some doubt if the present rate of sales gains can be sustained indefinitely.

Prices are firm and some advance appears almost inevitable if the cost of materials and current wage scales continue to stiffen. Not all the small-motor business of recent months is believed to have been booked at a satisfactory profit, some orders having been taken at figures chiefly attractive from the standpoint of keeping plants well occupied. There appears to be no general tendency to enlarge motor factories unduly against a heavy increase in business, and this conservative policy is reflected in present deliveries.

### Range Sales Improving as Season Develops

STEADY improvement in range sales continues as the season develops. Raw-material shortage is less troublesome, and some reserve capacity in plant facilities exists to meet an expanded demand. At present no serious labor shortage is reported in this branch of electrical manufacturing. Development work is making good progress toward the early marketing of a new moderate-priced range by a representative manufacturer, which will probably retail in the vicinity of $100. Central-station rates are being formed with closer regard to the commercial exploitation of ranges, and the outlook is good for the next few months' sales.

## The Metal Market

The extreme dullness which has characterized the metal markets in recent weeks continues in even more accentuated form, with no buying of consequence in any metal. That producers are feeling this lack of demand is indicated by further price reductions, though there is no disposition to force large tonnages on an unwilling market, and most producers are well sold up with current production. The lowering of prices would probably not amount to much were it not for the fact that prices have dropped considerably in London. The increased unwillingness to buy on the part of local consumers is without doubt caused by the feeling that prices are tending downward rather than up and that no more metal should be booked than is necessary for the needs of the immediate future.

Very few buyers have been interested in the offerings of producers, even at slight reductions in price. The larger interests are generally asking 17 cents delivered, but this price is admittedly a nominal one. A little copper was sold last week at 16⅞ cents delivered, and an occasional carload brought even as much as 17 cents, but later offers at these prices brought no response whatever. A fair tonnage was sold at 16.75 cents, largely for June and July delivery.

NEW YORK METAL MARKET PRICES

| | April 25, 1923 Cents per Pound | May 2, 1923 Cents per Pound |
|---|---|---|
| Copper, Electrolytic | 17.00 | 16.75 to 17.00 |
| Lead, Am. S. & R. price | 8.25 | 8.00 |
| Antimony | 8.37½ | 8.00 to 8.25 |
| Nickel, ingot | 28.00–30.00 | 28.00 to 30.00 |
| Zinc, spot | 7.37½ | 7.37½ |
| Tin, Straits | 46.62½ | 45.00 |
| Aluminum, 98 to 99 per cent | 26.00 | 26.00 |

The export market showed some signs of life last week, owing to favorable fluctuations in exchange, but it is again very weak. Sales during the week have netted producers on this side about 17⅝ cents for most of the business that has been done.

The official contract price of the American Smelting & Refining Company was reduced from 8.25 cents, New York, to 8 cents. This is the first reduction that has been made since June 22, 1921, when the price was established at 4.40 cents. The reduction was caused by the factors mentioned last week, namely, the decline in import costs, and the fact that lead was being offered by others at the 8-cent level.

## Comparative Prices of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | $0.0326 | $0.0322 | $0.0236 |
| Cold finished shafting, per lb. | 0.0406 | 0.0406 | 0.032 |
| Brass rods, per lb. | 0.1913 | 0.1904 | 0.15 |
| Solder (half and half), per lb. | 0.2987 | 0.314 | 0.21 |
| Cotton waste, per lb. | 0.1231 | 0.1231 | 0.104 |
| Washers, cast iron (½-in.), per 100 lb. | 4.66 | 4.50 | 4.00 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 2.96 | 3.11 |
| Machine oil, per gal. | 0.349 | 0.349 | 0.40 |
| Belting, leather, medium, off list | 42% | 42% | 48½% |
| Machine bolts, up to 1-in. x 30-in., off list | 44½% | 48½% | 62½% |

# Activities of the Trade

Devoted to News of the
Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Landers, Frary & Clark Announce Window-Display Contest

Announcement is made of the "Universal" electric iron window-display contest and national advertising campaign by Landers, Frary & Clark, New Britain, Conn.

Twelve cash prizes are offered for the twelve best window displays. The first prize is $100. The contest closes June 30 and is limited to dealers who have the company's "Universal" irons in stock or who had ordered them at the time this contest was first announced.

Every week for six consecutive weeks "Universal" advertisements will appear throughout the United States in more than fifty big metropolitan newspapers, reaching millions of people each issue.

## Century Electric to Reconstruct Six-Story Factory

The Century Electric Company, St. Louis, manufacturer of motors, has just contracted for the reconstruction of the six-story factory building at the southwest corner of Eighteenth and Pine Streets. The building adjoins the six-story building recently completed by this company on the south side of Pine Street opposite its main factory on the north side of Pine Street. A spacious tunnel has been constructed under Pine Street connecting the two factories on the opposite sides of the street.

The building to be reconstructed was built forty or fifty years ago as a carriage factory. With this addition the Century Electric Company will have a six-story factory on the south side of Pine Street, almost a block long. The additional building was made necessary by the tremendous increase in the Century company's business. Plans for the reconstruction work were prepared by L. Bayton Pendleton, architect, who will have entire supervision of the work.

## Commercial Truck Company Receives Order for 177 "Electrics"

The Commercial Truck Company, New York City, has received an order for 177 one-ton electric delivery wagons from the Wagner Pastry Company of Newark, N. J. This is one of the largest electric truck orders placed at one time.

Engineers of the Commercial Truck Company anticipate a saving to the pastry company of $100,000 a year at the Newark plant, where these "electrics" will replace an equal number of gasoline trucks and wagons. Before placing the order the company experimented on all of its seventy routes for a year.

The Commercial Truck Company has opened up a new garage at 542 East Nineteenth Street, New York City.

## E. W. Bliss Moves Sales Offices to South Brooklyn Plant

The E. W. Bliss Company, Brooklyn, N. Y., manufacturer of machinery, has moved its sales and executive offices to its South Brooklyn plant, at the foot of Fifty-third Street, on the east shore of the upper New York bay. This plant comprises a group of seventeen buildings covering a ground area of 18 acres and has a total floor area of 21 acres. It has a water frontage of 390 ft., on which there are two piers, one being 200 ft. long and 80 ft. wide and the other 575 ft. long and 60 ft. wide. There is ample water to accommodate the average-size steamship.

During the war many large additions were made to this plant to meet war requirements until it reached its present large proportions. At the termination of the hostilities a very considerable amount of space and equipment was available.

The Bliss company determined that consolidation of its two Brooklyn plants had decided advantages, and accordingly it has moved practically all the machine equipment from the Adams Street plant to the South Brooklyn plant, using the space made available by the dismantling of the special machinery which was necessary for war requirements.

## Apex Company's New Appointments

The Apex Electrical Distributing Company, Cleveland, home appliances, announces that Albert E. Richter, who has been Northwestern district sales manager of the company, with headquarters in Minneapolis, has been called back to the Cleveland factory as sales promotion manager. B. D. Schock, who formerly was Mr. Richter's assistant, has been appointed sales manager of the Northwestern district.

## Pure Carbon New Representative

Announcement is made by the Pure Carbon Company, Wellsville, N. Y., manufacturer of carbon motor brushes, of the recent establishment of a Minneapolis representative, the Charles A. Etem Company, 917-A Marquette Avenue.

## Anaconda's 1922 Business Was Largest in Its History

The Anaconda Copper Mining Company, for the year ended Dec. 31, 1922, reports gross revenue of $175,450,384, the largest for any year in the history of the company. The increase, however, was due to the acquisition of the properties of the American Brass Company in the early part of 1922. The total of $175,450,384 compares with a total of $33,113,231 in 1921. After payment of all operating expenses and reserves for federal taxes, the company reports net operating income of $11,432,044, against a net operating deficit of $6,257,042 the year before.

After providing for reserves for depreciation, bond interest and writing off of loss in connection with suspended mining operations during the first quarter of the year, the company reports a balance of $3,539,239 available for the 3,000,000 shares outstanding of capital stock of $50 a share par value, or the equivalent of almost $1.18 a share. In 1921, after all deductions for interest, reserves and other charges, the company reported a deficit of $17,061,189.

## National Carbon Sales Manager Praises Dealers as Stabilizers

James R. Crawford, general sales manager of the National Carbon Company, New York City, gave out the following interview during the recent joint convention of the Southern Hardware Jobbers' and the American Hardware Manufacturers' Association at Jacksonville, Fla.

"It is little short of marvelous," says Mr. Crawford, "the way in which the United States has recovered its stride after the disrupting march of the war. All of the dire predictions of the pessimists in regard to the difficulties we should experience in reabsorbing into our industrial life the great mass of discharged soldiers have proved false. All the wild and disquieting talk about the dangers of bolshevism and the spread of radical doctrines has likewise been shown to have had no foundation in fact.

"Particularly remarkable and gratifying is the brave 'comeback' from industrial depression that the South has made. I doubt if at any previous period the agricultural prospects of the Southern States were so promising. Aided by vast acreage reclaimed by draining and by intensive and scientific study of the soils, the Southern farmer and fruit grower is filling an ever larger space in the markets of the world. In industry also, especially in cotton weaving and kindred arts, the Southern States have entered into keen and healthy competition with the New England States. I am glad to note that Southern industries as well as those in other parts of the nation have apparently learned and taken to heart the lesson as to the value of advertising in the daily press. Very fine

barometers of business are the advertising columns of the daily paper, which, after all, is the best advertising medium in the world when backed up by the proper advertising to the jobber, wholesaler and retailer in the business trade press.

"One of the chief factors in bringing business back to normal has been the retail dealer. By co-operating with the jobber and manufacturer, the utilization of the most modern merchandising methods, the use of newspaper advertising, window displays and other advertising material, and by teaching his clerks salesmanship, he has speeded the wheels of commerce and aided in the task of re-establishing prosperity.

"Only a country as resilient, quick to sense new value and grasp new opportunities, a country with a spirit large enough to march alongside the splendid opportunities America offers, could have got back into a steady business step as quickly as our country has done. There has been no gulf created between capital and labor; instead there is a growing realization that the interests of capital and labor, so far from being opposed, are identical. Fearing a great influx of cheap labor from the distraught countries of Europe, our Congress passed a selective immigration law designed to keep our own American workmen from being swamped by cheap competition. Really such a law may not have been needed at all, for business and industry have taken on such sturdy, new vitality that there is actually a shortage of labor and there is no excuse for a man being without a job at good wages."

## Westinghouse Lamp Prices Cut

The Westinghouse Lamp Company, simultaneously with other lamp manufacturers, announces a reduction in prices of lamps amounting to from 8 to 10 per cent.

## Allis-Chalmers Sales in First Quarter Were $5,221,691

Sales billed by the Allis-Chalmers Manufacturing Company, Inc., Milwaukee, manufacturer of electrical machinery, amounted to $5,221,691.78 during the first quarter of 1923, with net profit of $468,689.62 after provision for federal taxes was made.

| | Sales Billed | Net Profit After Provision for Federal Taxes |
|---|---|---|
| January | $1,616,955.28 | $123,479.17 |
| February | 1,727,414.91 | 156,711.47 |
| March | 1,877,321.59 | 188,498.98 |
| | $5,221,691.78 | $468,689.62 |

## G. E. Turbine Generator Order

The General Electric Company has just received a contract for a 60,000-kw. cross-compound steam-turbine generator from the Commonwealth Edison Company of Chicago. This is the largest unit ever purchased by that company and will be installed in the new Crawford Avenue station. The ultimate capacity of the station will be from 500,000 kw. to 600,000 kw.

## Hessel Merges with Southern New England Company

The James T. Hessel Company, New Haven, Conn., and the Southern New England Electric Company, Waterbury, Conn., both electrical supply jobbers, have merged under the latter name, with headquarters at 19 Prout Street, New Haven. Branches have been established at Waterbury and Hartford, and another will be opened shortly at New London or Norwich. J. R. Spurr is president and James T. Hessel vice-president and general sales manager of the new organization.

**The Ohio Brass Company**, Mansfield, Ohio, will soon make additions to the plant of the Ohio Insulator Company, Barberton, Ohio, a subsidiary. Two buildings will be erected providing additional floor space of 16,000 sq.ft.

**The Sterling Insulated Wire Company** of Providence, was recently incorporated under the laws of Rhode Island to engage in the manufacture of insulated wire products, etc. The capital stock consists of 500 shares of common stock without par value, and the incorporators include William Shardlow of Pawtucket, R. I., and Francis J. Brady and Harold W. Thatcher, both of Providence.

**The Star Porcelain Company**, Trenton, N. J., manufacturer of electrical porcelain products, will establish a new branch at Annandale, N. J., to be used primarily for the production of steel dies. The present plant at Clinton, N. J., will be removed to the new location.

**The Tuska Electric Company**, Homestead Avenue, Hartford, Conn., manufacturer of electrical specialties, will construct a one-story plant addition, 30 ft. x 70 ft.

**Harry Alter & Company**, electrical jobbers, are moving to a new location at Ogden Boulevard and Carroll Avenue, Chicago. The company is to have a five-story building containing 51,000 sq.ft. of floor space.

**Schulz & Ingram, Inc.**, electrical engineers, 31 Broadway, New Haven, Conn., have been organized to specialize in maintenance and electrical repairs of equipment used in industrial plants. They also expect to manufacture special equipment. O. H. Schulz is president.

**The Universal Electric Stage Lighting Company**, 321 West Fiftieth Street, New York City, recently incorporated with capital stock of $400,000, is engaged in manufacturing lighting equipment and appliances. It takes over a business which has been established for about twenty-five years in making electric stage-lighting devices. The company occupies a four-story building which will later be increased to six stores. Incorporators are J. H., A. T. and L. Kliegel.

**The Ormor Sales & Supply Company**, recently organized by C. W. Orr and W. H. Moore, is the latest addition to the ranks of manufacturers' agents in Denver.

**Lewis B. Stillwell**, consulting engineer, on May 1 moved his offices to 90 West Street from 143 Liberty Street.

**Pelton Water Wheel Company.**—A new 8,500-hp. impulse wheel for the Pacific Gas & Electric Company has recently been shipped by the Pelton Water Wheel Company, San Francisco.

**The Campbell Transmission Company** announces the appointment of R. J. Dundon as sales manager, with headquarters in Watertown, N. Y.

**The Flexlume Corporation**, Buffalo, manufacturer of electric signs, now occupying the Curtiss airplane factory in Kail Street, has recently purchased the Ericsson plant in Military Road. The transaction involved approximately $500,000, and the corporation plans to move into the new quarters next September.

**The Blue Ridge Electric Company, Inc.**, 709 National Bank Building, Charlottesville, Va., recently capitalized with $10,000, will handle a complete line of equipment and supplies, acting as manufacturers' agents.

**The Chicago Mill & Lumber Company**, manufacturer of wooden boxes for electrical purposes, announces the removal of its offices to 510 North Dearborn Street, New Boyce Building, Chicago.

**W. J. Jeandron**, American representative of Le Carbone brushes, sailed for Europe last week for a six weeks' visit to the factory at Levallois-Perret.

**The Atwater Kent Manufacturing Company**, 5936 Stenton Avenue, Philadelphia, manufacturer of electric equipment, has purchased a tract of 15 acres of land at Abbotsford and Wissahickon Avenues and will use it as a site for a complete new plant. Plans for the initial unit have been authorized, estimated to cost approximately $225,000. The ultimate plant will comprise a number of units, estimated to cost approximately $1,000,000.

**The Connecticut Telephone & Electric Company**, Meriden, Conn., has acquired the plant formerly occupied by the Wilcox & White Company, defunct, heretofore used for the production of piano-player mechanisms, and will utilize the property for expansion. A main four-story building will be remodeled for a factory for the production of electrical insulating specialties. Other structures will be used for radio and electrical instrument manufacture. The power house will be increased in capacity with the installation of additional equipment. As a result of this acquisition the company will hold in abeyance the construction of its proposed new plant, for which plans recently were drawn and bids asked.

**The Gifford-Wood Company**, Hudson, N. Y., conveying equipment for power plants, has moved its office from Buffalo to Pittsburgh, where it is now established in the People's Bank Building, Fourth Avenue and Wood Street.

**John W. Hooley**, formerly of 45 Barclay Street, New York City, electrical engineer, moved on May 1 to 70 East Forty-fifth Street, Grand Central Terminal.

## Foreign Trade Notes

BILL PASSED BY THE FRENCH GOVERNMENT TO SUBSIDIZE ELECTRICAL ENTERPRISES.—A bill granting a subsidy of 600,000,000 francs to enterprises for the distribution and application of electricity has been passed by the French government.

PROPOSED HYDRO-ELECTRIC SCHEMES FOR ITALY.—Three decrees affecting hydro-electric schemes in the Province of Venice, Italy, have been approved by the Ministero dei Lavori Pubblici as follows: The granting of a concession to the Società Idroelettrica Veneta to utilize the waters of the River Paive, near Soverzene, Belluno, to generate electricity; the development of the water power of Longhella Falls, and the organization of the Consorzio di Bonifica di Dese Inferiore (trust for the development of the Lower Dese River). The Italian government has decided to organize an association of hydraulic experts, hydraulic power users and other specialists, etc., to be known as the Associazione Utenti Acque Pubbliche d'Italia, to survey, control and promote the utilization of water and water power in all its forms.

PROPOSED ELECTRICAL DISTRIBUTION SYSTEM IN FRANCE.—Application for a concession to distribute electricity in the departments of the Drôme Isère, Ardeche, Loire and Rhône has been made by the Société des Forces Motrices du Vercors. A concession has been applied for by the Société Electrique "La Lanterne," established at Conflans, to take in a large portion of the Haute-Saône department. A concession to furnish electricity in eleven communes in the department of Savoy has been asked by the Compagnie Savoisienne d'Electricité, and a similar application has been made by the Compagnie de Gaz et d'Electricité de Melun for the district of Melun (Seinet-et-Marne). The Société "Le Triphase" is seeking permission to erect a system to supply energy in thirteen communes in the Seine-et-Oise department.

PROPOSED ELECTRICAL SCHEME FOR CORSICA.—A project to supply electricity in Corsica is under consideration. The plans provide for four generating stations, one at Laucom of 1,600 hp., one at Tavignano of 1,250 hp., a third at Tarrano of 2,250 hp., and a fourth at Fiurmorbo of 3,200 hp. About 550 km. of 20,000-volt transmission lines, and 1,450 km. of 5,500-volt lines will be erected. The initial cost of the scheme is estimated at 45,850,000 francs.

HYDRO-ELECTRIC SCHEME ON RIVER ARDECHE PROPOSED.—Work will soon begin on the construction of a large hydro-electric scheme on the River Ardeche, France, to develop 42,000 kw. The cost of the project is placed at 75,000,000 francs, and it will require eight years to carry out the work.

HYDRO-ELECTRIC PROJECT IN FORMOSA.—Active work is expected to be resumed in the near future, according to *Commerce Reports,* on the Jitsugetsutan (Lake Candidius) hydro-electric project in Formosa.

## Foreign Trade Opportunities

The following inquiries have been received by the Philadelphia Commercial Museum, which will furnish names and addresses of the inquirers to any desiring them and mentioning the number given: Parties in Maracaibo, Venezuela (No. 40,649), would like to communicate with manufacturers of electrical supplies, etc. Parties in Turin, Italy (No. 40,653), would like to get in touch with manufacturers of filaments for incandescent lamps, carbon filaments, tungsten wire and rods, molybdenum wire and rods, borated copper-clad wire, discontinuous tungsten coils for half-watt lamps, which they wish to purchase and for which they also wish to act as sole agents. A party in St. Martin, French West Indies (No. 40,654), would like to receive catalogs and prices on telephone and telegraph material, ice-manufacturing and refrigerating machinery, surveying instruments, etc.

ALUMINUM STEEL-CORED CABLE FOR AUSTRALIA.—Tenders will be received by the Victorian Electricity Commission, Melbourne, Australia, until Aug. 31 for 500 miles of aluminum steel-cored cable.

ELECTRIC TRUCKS, MOTORS, ETC., FOR ARGENTINA.—Tenders will be received by the Department of Navigation and Ports, Buenos Aires, Argentina, until June 4 for electric motors and general machine shop equipment, electric battery trucks, ceiling, wall and table fans, machine tools, etc.

ELECTRIC MACHINERY FOR NAPIER, NEW ZEALAND.—Tenders will be received by the Borough Council of Napier, New Zealand, for one 500-kva. alternating-current generator and exciter set.

ELECTRIC PLANT FOR HONDURAN CITY.—Additional custom duties, *Commerce Reports* states, have been established by the Honduran Congress in order to raise the sum of $130,000 for the construction of a water system and electric light plant for the city of Comayagua. The Mayor (Alcalde) of Comayagua is president of a board to control the expenditure of the funds, including the making of all contracts for this construction work.

## New Apparatus and Publications

RADIO RECEIVING OUTFIT.—The Betts & Betts Corporation, 645 West Forty-third Street, New York City, is distributing radio bulletin No. 188, covering its various radio devices.

FREIGHT AND TRACK-HANDLING MACHINERY.—The Link Belt Company, Chicago, is distributing bulletin No. 375, describing its freight and track-handling equipment, together with labor-saving equipment.

LINEMEN'S BELTS AND SAFETY STRAPS.—Mathias Klein & Sons, 3,200 Belmont Avenue, Chicago, have issued a bulletin listing specifications covering their linemen's belts and safety straps.

TURBINES.—"Where Better Turbines Are Built" is the title of bulletin No. 103 issued by the Kerr Turbine Company, Wellsville, N. Y., which describes and illustrates its plant and gives some details regarding the manufacture of the "Kerr" turbines.

LIGHTING UNIT.—The F. W. Wakefield Brass Company, Vermilion, Ohio, has added a ceiling unit to its "Red Spot" lighting specialties. It is especially adaptable for kitchens and bath rooms.

STEAM ATOMIZER REGISTER.—The Engineer Company, 17 Battery Place, New York City, has issued an instruction book entitled "Enco S-A-R" (Steam Atomizer Register), which gives instructions for the care and operation of "Enco" oil-burning installations.

RETURN TUBULAR BOILERS.—"Uniflow Improved Return Tubular Boilers" is the title of a booklet issued by the Lebanon Boiler Works (J. K. Petty & Company, Inc., proprietors, Lebanon, Pa.) describing the "Uniflow" boiler.

PULVERIZED-COAL EQUIPMENT.—The Ground Coal Engineering Corporation, Worcester, Mass., is distributing bulletin No. 72, which describes and illustrates the "Multi-Mix" method of burning pulverized fuel. The company is represented by the Sanford Riley Stoker Company, Worcester, Mass.

VACUUM CLEANER.—An electric vacuum cleaner ("Magnetic") has been placed on the market by the Birtman Electric Company, 640 West Lake Street, Chicago.

CUTTING MACHINE.—A machine for cutting gaskets, display signs, etc., has recently been developed by the International Register Company, 15 South Throop Street, Chicago.

## New Incorporations

THE ARKANSAS CENTRAL POWER COMPANY, Little Rock, Ark., has been chartered to take over the property of the Little Rock Railway & Electric Company. The officers are: D. H. Cantrell, president; A. Brizzolara, vice-president and treasurer; W. J. Tharp, secretary and auditor, and C. J. Griffith, general manager.

THE LEGGETTS (N. C.) ELECTRIC COMPANY, post office Tarboro, has been incorporated with a capital stock of $15,000 by Theodore Fountain and others.

THE WALWORTH (N. Y.) Light & Power Company has been incorporated by E. J. Blythe, A. J. Esley, F. A. Boynton and G. R. Wignall, all of Walworth. The company is capitalized at $20,000 and proposes to supply electricity in the towns of Walworth, Macedon, Palmyra, Ontario and Williamson.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

UNION, ME.—The Central Maine Power Company, Augusta, is planning to build a 3,500-hp. power plant at Union to supply electricity in Knox County. A new transmission line will be erected from Union to Rockland. The cost is estimated from $300,000 to $350,000.

FALL RIVER, MASS.—Work will soon be commenced on the tidewater power plant to be erected for the Montaup Electric Company, to cost about $5,000,000, with transmission system. The initial installation will have a capacity of 30,000 kw. A second unit of same capacity will be installed at an early date. Stone & Webster, Inc., 127 Milk Street, Boston, are engineers.

SPRINGFIELD, MASS.—The United Electric Company will build a meter service station at Baxter and Wilbraham Streets, to cost about $65,000. H. L. Sprague, 310 Main Street, is architect.

NEW BRITAIN, CONN.—The State Board of Education, Hartford, plans to build a power plant at the camp school division of the State Normal School, to cost about $45,000.

## Middle Atlantic States

COLLEGE POINT, N. Y.—The Purvis Machine Company has filed plans for a one-story addition, 30 ft. x 45 ft., to its steam-power plant.

JAMESTOWN, N. Y.—Bids will be received by the Board of Water and Light Commissioners, City Hall, until May 10 for miscellaneous incandescent electric lamps.

LAWRENCE, N. Y.—The Long Island Lighting Company, 50 Church Street, New York, contemplates extensions and improvements in the power plant and system of the Queens Borough Gas & Electric Company, recently acquired.

NEW YORK, N. Y.—Bids will be received at the office of the supervising architect, Treasury Department, Washington, D. C., until May 8 for furnishing and installing fire-alarm and watchman's call systems in the United States Veterans' Hospital, Webb Avenue and Kingsbridge Road, Bronx, N. Y.

NEW YORK, N. Y.—The American Smelting & Refining Company, 120 Broadway, contemplates the construction of a power plant in connection with a proposed copper and zinc smelting plant in Mexico. Electric power equipment will also be installed at the company's coal properties at Rosita, Mexico.

TOTTENVILLE, N. Y.—Electric power equipment will be installed in the plant to be erected by the Tottenville Copper Company to replace its works recently destroyed by fire, causing a loss of about $1,000,000.

CAMDEN, N. J.—The Philadelphia & Reading Railroad Company is preparing plans for a power plant to be built at its local terminal, now in course of erection, to cost about $150,000.

CAPE MAY, N. J.—The Atlantic City Light & Power Company has acquired the system of the Cape May Power & Light Company and will operate it in conjunction with its Wildwood plant. Extensions and improvements are planned. The installation of a lighting system on the Rio Grande Boulevard is under consideration.

MAYS LANDING, N. J.—The Atlantic Brick Company will rebuild its power house and plant, recently destroyed by fire, causing a loss of about $150,000.

NEWARK, N. J.—Electric power equipment will be installed in the printing plant to be constructed by the Newark *Evening News,* 215 Market Street, to cost about $200,000. Henry D. Scudder, Jr., 9 Clinton Street, is architect.

NEWARK, N. J.—The Public Service Electric Company will build an automatic substation on Norfolk Street. The equipment will include two 1,500-kw. motor-generator sets, six 2,000-kw. transformers, etc.

CHRISTIANA, PA.—The Christiana Planing Mills, Inc., will install electric

power equipment in connection with the rebuilding of its plant recently damaged by fire, causing a loss of about $100,000.

HARRISBURG, PA. — The Harrisburg Light & Power Company will build a two-story operating works at Walnut and Ninth Streets, to cost $30,000.

NORRISTOWN, PA.—Plans are under way by the Counties Gas & Electric Company for the construction of a 65,000-hp. power plant on Barbadoes Island, Schuylkill River, to cost about $400,000.

PHILADELPHIA, PA. — The Modern Laundry Company, 4089 Market Street, will build a one-story power house at Filbert and Forty-first Streets, to cost $25,000. William Lowenthal, 1208 Chestnut Street, is engineer.

PHILADELPHIA, PA. — The General Baking Company, Butler and Broad Streets, plans to build a one-story power house to supply power for its plant. C. B. Comstock, 110 West Fortieth Street, New York, is engineer.

PHILADELPHIA, PA. — Electric power equipment, refrigerating apparatus, etc., will be installed at the plant of the Abbotts Alderney Dairies, Inc., 222 Lombard Street, which will be enlarged and improved at a cost of $600,000.

WEST CHESTER, PA.—The West Chester Cold Storage & Ice Company will rebuild its power house and plant, recently damaged by fire, causing a loss of about $90,000.

CONOWINGO, MD. — The Susquehanna Power Company, a subsidiary of the United Gas & Electric Company, 61 Broadway, New York, contemplates the construction of a hydro-electric plant on the Susquehanna River at Conowingo, with ultimate capacity of 360,000 hp., to cost about $1,500,000. The plans include a transmission line.

CHARLESTON, W. VA.—The Virginia Power Company plans to build a 50,000-hp. generating plant at the mouth of Cabin Creek, to cost about $450,000.

HUNTINGTON, W. VA.—Electric power equipment will be installed at the plant of the West Virginia Rail Company, Second Avenue, in connection with additions to cost about $250,000.

ALTAVISTA, VA.—The Lane Company, Inc., has engaged Lockwood, Greene & Company, Charlotte, N. C., engineers, to prepare plans for a 600-hp. power plant at its cedar-chest manufacturing works.

## North Central States

GRAND RADIPS, MICH.—The Valley City Milling Company, 217 Michigan Street, contemplates the installation of a power house at its proposed flour mill on Turner Street, to cost about $600,000.

CLEVELAND, OHIO. — Two ornamental lighting systems, one to be installed on St. Clair Avenue and the other on East 105th Street, to cost about $100,000, have been approved by the City Board of Revisions and Assessments.

IRONTON, OHIO.—The Hecla Mining & Manufacturing Company, recently organized, is planning to erect a large electric plant to supply electricity for its properties and for commercial purposes.

JACKSON, OHIO.—The installation of gas engines in the municipal electric plant is under consideration. R. L. Lamb is director of public service.

SPRINGFIELD, OHIO. — Arrangements are being made by the Springfield Light, Heat & Power Company to place a large number of feed wires and cables underground in the downtown section of the city.

UPPER SANDUSKY, OHIO.—Arrangements are being made by the Council for the erection of a substation to distribute electricity to be supplied by the Ohio Power Company. Preparations are being made by the company to serve Carey, Sycamore and Alvada, as well as Upper Sandusky.

URBANA, OHIO. — The Northwestern Ohio Light Company contemplates the erection of a transmission line from its local plant to Kings Creek and also a line to Fremont City to supply electricity in those towns and to residences along the route.

MIDDLESBORO, KY.—The construction of a large hydro-electric plant on the Cumberland River in Bell County is under consideration by the Kentucky Utilities Company. An option has been obtained on a site near Pineville.

FORT WAYNE, IND.—Extension of the ornamental lighting system on Wayne Street is under consideration by the Board of Works.

FORT WAYNE, IND.—The International Harvester Company plans to build a one-story power house at its local motor-truck factory.

MUNCIE, IND.—Bids are being asked for the construction of a power house at the Indiana State Normal School and for furnishing two boilers with stokers, etc.

RICHMOND, IND.—The construction of a new power house, to cost about $70,000, is under consideration by the board of trustees of the Eastern Indiana Hospital.

RUSHVILLE, IND.—Improvements, it is reported, are contemplated to the municipal water and light plant, including an addition to the power house.

WHITEHALL, ILL.—Bonds to the amount of $54,000 have been voted for the installation of a municipal electric light plant.

EAU CLAIRE, WIS. — The Wisconsin-Minnesota Light & Power Company is considering plans for the construction of additional plants at Holcomb, Chippewa Falls and Dunnville.

EAU CLAIRE, WIS. — The Wisconsin-Minnesota Light & Power Company plans to erect a new transmission line from its Jim Falls hydro-electric plant on the Chippewa River to Hastings, Minn. The company also contemplates the erection of a high-tension transmission line from its Wissota Dam to Red Wing, Minn., a distance of 60 miles.

GREEN BAY, WIS.—The Wisconsin Public Service Corporation is considering the erection of a transmission line which will connect its Peshtigo and Oconto electric plants with its plants at High Falls, Menominee, Green Bay and Manitowoc.

HILLSBORO, WIS.—The Middle Wisconsin Power Company is reported to be negotiating for the purchase of the property of the Hillsboro Light & Power Company. Arrangements are being made by the Middle Wisconsin Power Company to extend its light and power lines from Union Center to this city.

KAUKAUNA, WIS.—The construction of a steam generating plant, to cost about $50,000, is under consideration by the Thilmany Pulp & Paper Company.

MILWAUKEE, WIS.—The installation of an improved street-lighting system on Center Street is under consideration by business men on that thoroughfare.

RHINELANDER, WIS.—The Rhinelander Light & Power Company is installing a 1,000-kva. generating unit, and waterwheel, and is also erecting an addition to power house and dam. E. W. Boyce is secretary and treasurer.

FOSSTON, MINN. — Arrangements have been made with the Northern States Power Company to extend its transmission line to Fosston this summer.

RED LAKE FALLS, MINN.—The Red River Power Company, Grand Forks, N. D., contemplates erecting a transmission line from Red Lake Falls to Terrebone, a distance of 28 miles, to cost about $32,000.

CHEROKEE, IOWA. — The Cherokee Electric Company plans to erect a new power house, 40 ft. x 100 ft., and will install new equipment.

FULTON, MO.—An election will be held May 8 to vote on the proposal to issue $50,000 in bonds for the erection of a transmission line and substation equipment for the municipal electric system and for waterworks expansion.

NEVADA, MO. — The National Asphalt Refining Company, recently organized, plans to build a power house at its proposed local refinery. The cost of the project is estimated at $450,000.

STOCKTON, MO.—The Stockton Electric Light Company contemplates the construction of a hydro-electric power plant on the Sac River, to cost about $90,000.

CHANUTE, KAN.—Bids will be received by C. G. Wood, city clerk, until May 8, for equipment for the municipal electric plant as follows: One 1,000-kw. turbo-generator, one surface condenser and pumps, one auxiliary exciter set, 30 kw., steam-driven, and two switchboards.

MEADE, KAN. — Extensions and improvements to the municipal electric light plant are under consideration.

## Southern States

BARNWELL, N. C.—Plans for the proposed local mill, to cost about $65,000, to be erected by the Barnwell Veneer Company include a power plant.

FAYETTEVILLE, N. C.—The Carolina Power Company is preparing plans for a local power plant, to cost about $750,000, including transmission line extensions.

GREENSBORO, N. C.—The Hill Flour Mills Company will install electric power equipment at its proposed milling plant, to cost about $200,000.

HIGH POINT, N. C.—The Lucas Lumber Company plans to build a power house in connection with a proposed local mill, to cost about $200,000.

SOUTHMONT, N. C.—C. M. Wall & Son plan to rebuild their mill and power house, recently destroyed by fire, causing a loss of about $150,000.

TRYON, N. C.—The Blue Ridge Power Company is preparing plans for a hydro-electric power plant to cost about $500 000. A steel-tower transmission line will be built, to cost $125,000. Mees & Mees, Charlotte, are engineers.

WACO, N. C.—The Rhodes Cotton Mills, Inc., plans to build a one-story power house in connection with a mill addition, to cost about $200,000.

ATLANTA, GA.—Additional plans of the Georgia Railway & Power Company include the construction of four new hydro-electric plants, substations and transmission lines, to cost about $11,568,000, work to be completed by the end of 1926. This, with the appropriation for 1923, will make more than $18,000,000 for new construction. Besides the Tugalo dam, work will be started on the Mathis-Tallulah power plants.

CLEVELAND, GA.—The Council is considering the construction of a municipal electric plant and a sewage and garbage disposal plant.

CLINTON, GA.—The Lydia Cotton Mills, Inc., plan to build a 1,500-hp. electric power plant in connection with a new local mill, to cost $130,000. Lockwood, Greene & Company, Charlotte, N. C., are engineers.

MOUNT DORA, FLA.—At an election to be held May 12 the proposal to issue $40,000 in bonds for an electric light plant will be submitted to the voters.

CEDAR SPRINGS, TENN.—The Wright & Pile Lumber Company will build a power house at its proposed local lumber mill, to cost about $90,000.

LAWRENCEBERG, TENN.—Plans are being prepared for the installation of a municipal power plant on Shoal Creek, to cost about $100,000.

BIRMINGHAM, ALA. — Electric power equipment will be installed in the new ice plant to be erected by the Birmingham Ice & Cold Storage Company, to cost about $400,000.

BIRMINGHAM, ALA. — The Alabama Power Company has petitioned the Public Service Commission for permission to erect a transmission line to connect the towns of Tuskegee, Union Springs, Childersburg, Waverly and Wetumpka, and to install electric distributing systems in each of the towns.

DOTHAN, ALA.—Bonds have been authorized by the city of Dothan for the construction of a hydro-electric plant on the Choctowhatchee River, about 20 miles from the city. The cost is estimated at from $800,000 to $900,000. The Ludlow Engineers, Inc., Winston-Salem, N. C., will have charge of the work.

HEFLIN, ALA.—W. M. Dodson, Wedowee, has been granted a local franchise and will erect a transmission system and substation, to cost about $30,000.

KREOLA, MISS.—The Southern Paper Company contemplates extensions to its mill at Moss Point, including a power plant and machine shop. The cost of the work is estimated at about $1,500,000.

PURVIS, MISS.—Bonds to the amount of $12,000 have been voted for the installation of an electric light and power system.

HOPKINSVILLE, ARK.—The local electric light plant and ice factory, owned by J. Dragoo, was recently destroyed by fire.

LITTLE ROCK, ARK.—The Arkansas Central Power Company, recently organized, has taken over the property and holdings of the Little Rock Railway & Electric Company, including local electric and traction systems. C. J. Griffith is general manager.

AGURES, LA.—Negotiations are under way for the establishment of an electric light plant in Agures.

SHREVEPORT, LA.—Preliminary plans are under consideration for a bond issue of $500,000 for the construction of a municipal electric plant.

GRANBURY, TEX.—Bids will be received by the Mayor and the City Council until May 9 for two crude-oil engines directly connected to alternators, two motor-driven centrifugal pumps, motor-driven air compressor, switchboard, etc. Proposals to be addressed to Mrs. Neil Hiner, City Secretary. The Municipal Engineering Company, Praetorian Building, Dallas, is engineer.

GREENVILLE, TEX. — The Greenville

Mill & Elevator Company contemplates the construction of a power house at its proposed local flour mill, to cost about $300,000.

TEXARKANA, TEX.—Electric power equipment will be installed in the ice-manufacturing and cold-storage plant, to be erected at Oak and West Broad Streets, at a cost of $100,000.

## Pacific and Mountain States

DEER PARK, WASH.—The Mount Spokane Power Company is planning to erect three rural transmission lines this summer.

KELSO, WASH.—Contract has been awarded by the Long-Bell Lumber Company for the construction of an electric plant. The ultimate capacity will be 16,000 hp., consisting of six units, three of which will be installed at once. The proposed plant will supply electricity for the town of Longview as well as for the mill. The cost is estimated at about $2,000,000.

PORTLAND, ORE.—The Portland Railway, Light & Power Company has issued $2,000,000 in bonds, part of the proceeds to be used for extensions and improvements.

REEDSPORT, ORE.—The Umpqua Mills & Timber Company will build a power house in connection with its proposed lumber mill, to cost about $100,000.

ST. HELENS, ORE.—The Columbia County Lumber Company plans to construct a power house and mill to replace its plant recently destroyed by fire, causing loss of about $300,000.

LOS ANGELES, CAL.—Bids will be received by the Board of Supervisors until May 14 for a 200-kw. motor-generator set and control equipment to be installed in the Hall of Records.

MARYSVILLE, CAL.—The Pacific Gas & Electric Company contemplates an addition to its local substation, to cost about $50,000.

MODESTO, CAL.—Bids will soon be called for the installation of a power distribution system. H. A. Storrs is consulting electrical engineer.

SAN BERNARDINO, CAL.—The Inland Oil Refining Company, recently organized, plans to build a substation in connection with a new refinery on West Rialto Avenue, to cost about $110,000.

LOGAN, UTAH.—A special election will be held on May 15 to vote on the proposal to issue $300,000 in bonds to rebuild the municipal power plant in Logan Canyon.

DENVER, COL.—A permit has been granted the Denver Tramway Company for the construction of a substation at 3,555 Gilpin Street.

WARD, COL.—Preliminary plans have been prepared by C. W. Thuringer, engineer, East Forty-second and Josephine Streets, Denver, for the construction of an electric smelter and a 40,00-hp. hydro-electric plant, to cost about $500,000. Owner's name withheld.

RENO, NEV.—The Sierra Pacific Electric Company has issued $1,643,800 in capital stock, part of the proceeds to be used for extensions and improvements.

## Canada

SOUTH VANCOUVER, B. C.—The British Columbia Electric Railway Company is planning to erect an automatic substation near Main Street. The cost of the equipment is estimated at $39,000.

CLIFFORD, ONT.—The installation of a municipal electric light plant is under consideration by the Town Council.

NORTH BAY, ONT.—Bids, it is understood, will soon be asked by the Temiskaming & Northern Ontario Railway Company for the construction of an electric branch line from either Dane or Swastika stations eastward to Lake Larder, 25 miles of single track. S. B. Clement is chief engineer.

NORTH BAY, ONT.—The Nipissing Central Railway Company contemplates building an electric railway eastward from New Liskeard into Quebec and then northward to Larder Lake from 60 to 80 miles, ultimately connecting with the Temiskaming & Northern Ontario Railway branch from Dane. The cost is estimated at about $3,000,000. S. B. Clement is chief engineer.

SARNIA, ONT.—The Hydro-Electric Power Commission of Ontario is preparing plans for extending the light and power lines from Sarnia to Corunna and Courtright, at a cost of about $42,000. E. R. Lawler, 190 University Avenue, Toronto, is engineer.

TORONTO, ONT.—Extensions will be made to the substation on Bay Street of the Toronto Hydro-Electric Commission, to cost about $90,000.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued April 10, 1923)

1,450,919. RHEOSTAT; P. Harris, New York, N. Y. App. filed July 15, 1922. Used in connection with storage batteries for wireless apparatus.

1,450,964. INCANDESCENT ELECTRIC LAMP; G. W. Turner, Cleveland, Ohio. App. filed Feb. 4, 1921. Method of renewing filaments.

1,450,966. SYNCHRONIZING SYSTEM; H. A. Affel, Brooklyn, N. Y. App. filed Sept. 30, 1919. For multiplex carrier-current communication systems.

1,450,969. RECEIVING CIRCUITS FOR WEAK SIGNAL CURRENTS; J. R. Carson, New York, N. Y. App. filed June 18, 1918. For long submarine cables.

1,450,970. TROLLEY HANGER; F. Chesszneky, Yukon, W. Va. App. filed Dec. 8, 1922. Clamping ear.

1,450,972. OUTLET BOX; L. H. Church, Roselle, and G. C. Thomas, Jr., Elizabeth, N. J. App. filed Aug. 19, 1921. Adjustable means for clamping cable or conduit therein.

1,450,998. HIGHWAY CROSSING SIGNAL; E. W. Vogel, Oak Park, Ill. App. filed March 3, 1920. Magnetically operated.

1,451,003. STORAGE BATTERY; W. H. Wood, South Euclid, Ohio. App. filed March 28, 1921. Separator of porous wood impregnated with magnesium sulphate.

1,451,024. COMBINED RHEOSTAT AND SOCKET; C. Klemmer and W. P. Koechel, Bogota, N. J. App. filed April 4, 1922. For radio apparatus.

1,451,051. WRAPPING AND UNWRAPPING MACHINE; F. M. Pierce, Chicago, Ill. App. filed Sept. 11, 1917. For the manufacture of tread-wrapped tires.

1,451,058. GRID PLATE FOR ELECTRIC CURRENT STORAGE BATTERIES; R. O. Shatzke, Denver, Col. App. filed Feb. 6, 1922. Allows for expansion and contraction.

1,451,166. SIGNAL DEVICE; D. J. McCarthy, Elgin, Ill. App. filed May 27, 1920. Polychromatic signal device from which shaft of light of selected color may be projected.

1,451,264. MOLD OR FORM; H. F. A. Kleinschmidt, Johnstown, Pa. App. filed June 4, 1921. For electrically uniting abutting ends of railway rails.

1,451,271. VAPOR-ARC LAMP; H. C. Rentschler, Wilkinsburg, Pa. App. filed Feb. 27, 1919. Concentrated-point light.

1,451,280. MILL; A. Sundh, Hastings-upon-Hudson, N. Y., and W. Westerman, Detroit, Mich. App. filed Oct. 8, 1920. Electrically operated device for indicating amount of material that is passing through mill.

1,451,281. INDICATOR; A. Sundh, Hastings-upon-Hudson, N. Y., and W. Westerman, Detroit, Mich. App. filed Oct. 8, 1920. Applied to mills for indicating the travel material through of mill.

1,451,283. THERMOCELL; J. L. Weatherwax, Wilkinsburg, Pa. App. filed Feb. 27, 1919. Means for varying pressure in thermocell tubes to change thermal electromotive force of couple.

1,451,328. ELECTRIC SIGNAL TRANSMITTER; D. Desplate, Buenos Aires, Argentina. App. filed Nov. 4, 1919. Push button type.

1,451,333. ART OF MAKING ELECTROLYTIC IRON; F. A. Eustis, Milton, C. R. Hayward, Quincy, and H. M. Schleicher and D. Belcher, Boston, Mass. App. filed Dec. 1, 1920. Electrolytic iron made by reducing ferric solution by electric current to ferrous state and then transferring ferrous solution to separate electrolytic cell.

1,451,347 and 1,451,348. STORAGE BATTERY; W. H. Thorpe, Mount Vernon, N. Y. App. filed Feb. 1, 1922. Automatic means for keeping proper amount of electrolyte in battery.

(Issued April 17, 1923)

1,451,678. VARIABLE-RESISTANCE UNIT; W. J. Cameron, Chicago, Ill. App. filed May 9, 1921. For controlling electric heating devices.

1,451,687. ELECTRICALLY HEATED BURNISHING MACHINE; H. E. Dow, Beverly, Mass. App. filed May 6, 1921. For burnishing sole edges of boots and shoes.

1,451,704. ATTACHMENT PLUG; S. McClatchie, Cambridge, Mass. App. filed Sept. 2, 1919. One-piece insulating body adapted to slip into a threaded socket shell.

1,451,746. MULTIPLEX SELECTING CIRCUITS; M. Sultzer, Brooklyn, N. Y. App. filed Dec. 23, 1921. Selective arrangements for multiplex signalling channel.

1,451,758. MANUFACTURE OF DRY-BATTERY CANS; F. G. Breyer and W. H. Finkeldey, Palmerton, Pa. App. filed Jan. 12, 1922. Uniform corrosion of zinc takes place in normal action of battery.

1,451,767. COMPOSITE RINGER FOR MULTIPLEX-TRANSMISSION SYSTEMS; L. Espenschied, Hollis, N. Y. App. filed Sept. 27, 1919. Interference between the various carrier currents eliminated.

1,451,801. PROCESS FOR HANDLING, DRYING AND FORMING PASTED BATTERY PLATES; C. M. Angell, Chicago, Ill. App. filed April 1, 1922.

1,451,847. ELECTRICALLY HEATED AND CONTROLLED STEAM BOILER; W. H. Rowe, Jacksonville, Fla. App. filed Feb. 10, 1922. Automatic control as to pressure and water content.

1,451,863. LIQUID HEATER; W. F. Clark, Warren, Pa. App. filed April 2, 1921. Water circulated through and around the heating element.

1,451,877. ADVERTISING DEVICE; J. E. Koehler and R. Paul, Chicago, Ill. App. filed Feb. 6, 1922. For doors or gates.

1,451,880. ELECTRIC HEATING APPLIANCE; E. N. Lightfoot, New York, N. Y. App. filed Feb. 28, 1921. Elongated electric heater arranged within a casing and embedded in metal contained therein.

1,451,885. PRIVATE-BRANCH-EXCHANGE SYSTEM; M. L. Nelson, Chicago, Ill. App. filed July 9, 1917. Subscribers establish connections by means of automatic switching mechanism.

1,451,886. SIGNALING APPARATUS FOR TELEPHONE SYSTEMS; M. L. Nelson, Chicago, Ill. App. filed June 13, 1921. Audible signaling equipment for automatic telephone systems.

1,451,894. ELECTRIC RIVETING MACHINE AND PROCESS; A. B. Rypinski, Laurelton, N. Y. App. filed Jan. 26, 1921.

1,451,896. TELEPHONY; H. S. Turner, San Diego, Cal. App. filed Feb. 27, 1915. Switchboard systems of the central-energy multiple type.

1,451,900. ELECTRICAL SIGNALING AND RECORDING SYSTEM; J. M. Diegel, Minneapolis, Minn. App. filed Dec. 6, 1920. For automatic journal and fire alarms, fire doors, etc.

1,451,912. TELEPHONE TRUNKING SYSTEM; A. E. Keith, Hinsdale, Ill. App. filed May 21, 1907. Automatic system in units of fifty subscribers' lines with ten first selectors.

1,451,968. INSULATOR; L. Steinberger, Brooklyn, N. Y. App. filed July 25, 1918. Strain insulator with heat-resisting covering.

1,451,969. INSULATED CONNECTOR; L. Steinberger, Brooklyn, N. Y. App. filed May 23, 1919. Connectors in which bodies of oil are utilized as insulating element.

1,451,979. ELECTRIC CONDUCTOR COUPLING; T. H. Penn, Cleveland, Ohio. App. filed May 17, 1921. Particularly designed for factory buildings, machine shops, etc.

1,452,032. OSCILLATING GENERATOR FOR SIGNALING SYSTEMS; J. F. Farrington, New York, N. Y. App. filed April 30, 1918. Vacuum-tube type with feed-back coupling.

1,452,064. RADIO TRANSMITTER; V. Bush, Chelsea, Mass. App. filed Nov. 22, 1918. Closed circuit of impact type in which a series of undirectional pulses are produced.

1,452,115. DIMMING MECHANISM; A. Herz, Chicago, Ill. App. filed July 24, 1918. Utilizes inductance coil.

1,452,143. DYNAMO FRAME AND METHOD OF FORMING THE SAME; J. Purke, Erie, Pa. App. filed Nov. 6, 1919.

1,452,157. INDICATOR MOTOR; C. J. Henschel, Brooklyn, N. Y. App. filed Sept. 18, 1820. Remote control of motors actuating indicators.

1,452,158. TRANSFORMERS; S. Horelick, Pittsburgh, Pa. App. filed July 21, 1921. Arrangement of coils for high-tension units.

1,452,163. CURLING-IRON HEATER; H. G. Levy, San Francisco, Cal. App. filed March 14, 1921.

1,452,169. SYSTEM OF ELECTRICAL CONSTRUCTION; A. T. Sampson, Lynn, Mass. App. filed May 7, 1917. Layout of conduit system.

1,452,194. ELECTRICAL TESTING CLIP; G. B. Dusinberre, Elmira, N. Y. App. filed June 22, 1921. Spring clip.

1,452,207. DEHYDRATOR; W. Meredith, Alameda, Cal. App. filed Oct. 28, 1920. Emulsion circulates in path of electrical discharge.

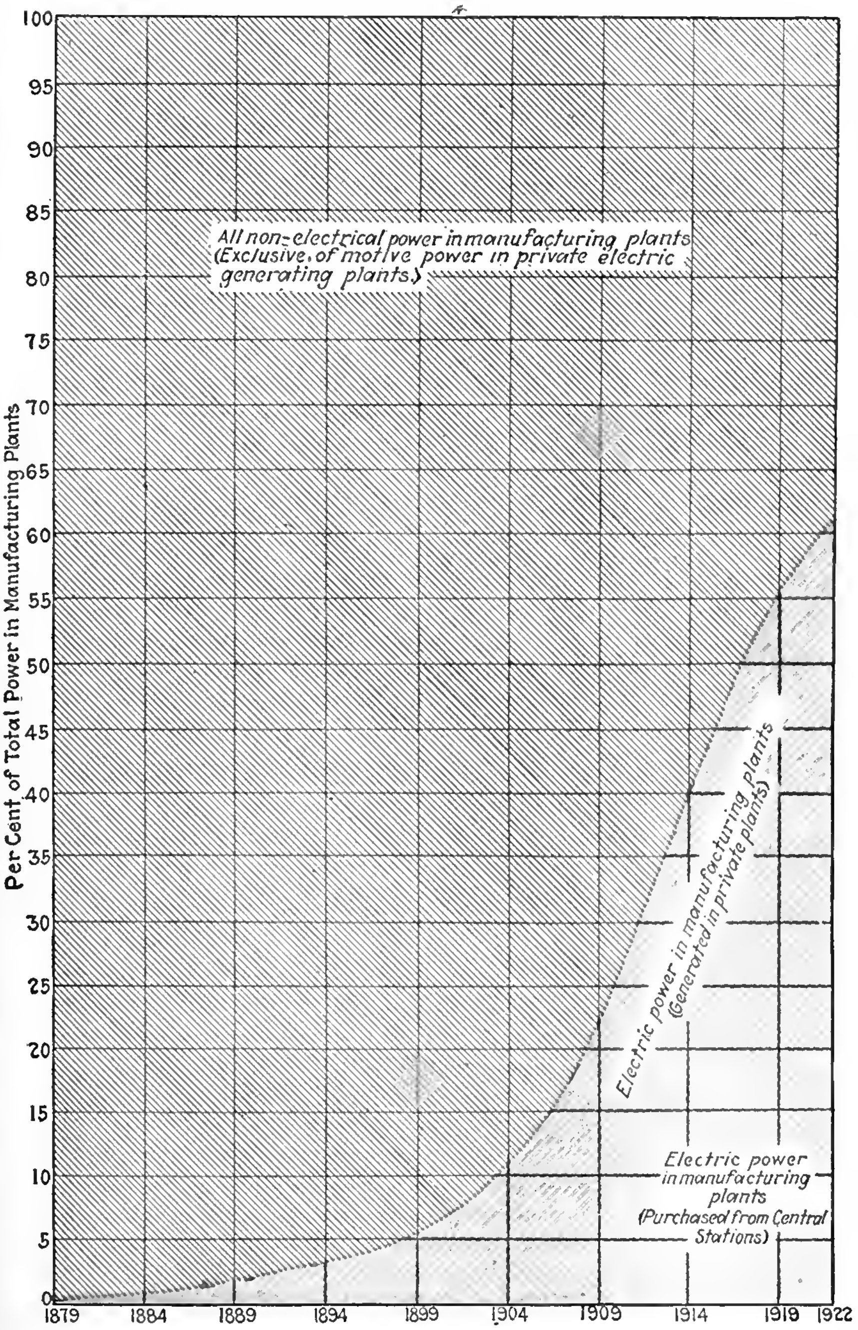
1,452,212. BRAKE-ACTUATING MECHANISM; R. A. Neal, Lexington, Ky. App. filed July 20, 1921. Electrically controlled brake for automobiles.

1,452,230. HIGH-POWER DRY BATTERY; A. A. Wells, Montclair, N. J. App. filed Jan. 2, 1918. Of Leclanché type.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business

## Approximately 61 per Cent of the Primary Power in American Manufacturing Plants Is Now Electrical



Most of the data for statistics in the Electrical World are gathered by it from original sources. Privilege is freely given to readers of the Electrical World to quote or use these statistics for any legitimate purpose. While there is no requirement that the source of data be given, yet it would help the Electrical World in obtaining and compiling further basic information if those using these statistics in any manner would credit the Electrical World.

## The Conquering Force in American Manufactures

The wholesale adoption of electric drive by the manufacturing plants of the country during the past forty years reads like the story of the automobile. In fact, these two great servants of mankind, electrical energy and gas propulsion, have experienced much the same skyrocket type of growth, and yet a growth which has so intertwined these forces into the very economic being of the nation that they will endure as long as the nation itself. And yet there will probably always remain certain types of service which the horse can accomplish more efficiently and economically than the gas-driven machine, and the steam engine and water-wheel will probably always fill most effectively a certain niche in our industrial life.

The accompanying diagram, based on United States Census data and data collected by Electrical World through its four-year, nation-wide industrial survey, tells very effectively the story of the adoption of electric-drive by the manufacturing plants of the country, and the consequent decrease in steam, hydro and gas-driven machinery in the factories and mills of the land.

In 1879 steam and hydro power held full sway as the forces turning the wheels of industry. By 1922 electrical energy had pushed all other forms of machine-drive into the background, leaving the steam, hydro and gas-drive only 30 per cent of the total horsepower of the manufacturing establishments of the country. But the installation of electric motors in new plants and the conversion of steam drive to electric drive is still on the increase, with a consequent further decrease in the percentage of other forms of energy. The day does not seem far distant when three quarters of the motive power of the factories and mills as a whole will be electric.

Another very significant fact to be drawn from the diagram is the increasing proportion of electrical energy supplied by central stations as opposed to private plant generation. Back in 1904 more than 72 per cent of the electric motor load was carried by private generating plants. Today only about 30 per cent is carried by private plants and 61 per cent by central stations, and every year is witnessing the advance of the central station into the territory of the private plant.

## Bank Cash Exceeds Needs for Credit

THE present lending capacity of the country's banking system is now far in excess of the credit needs of the country's productive activity, according to the monthly review of the New York Federal Reserve District. The review also shows the following as among the increases that have taken place since July 1, 1921: Production, 67 per cent; employment, 28 per cent; wholesale trade, 23 per cent; retail trade, 15 per cent; prices, 15 per cent, and wages of unskilled labor, 22 per cent.

# "Vice-President in Charge of Sales"

EXECUTIVES of central-station companies are beginning to appreciate more fully that their business, like any other, is built on the plan of a three-legged stool. The three legs which support it are finance, production and sales. Kick any one of these legs from under and the stool falls.

Since the beginning the attention of the executive has been closely, and naturally, focused on two legs mainly. He has been absorbed in the problems of engineering and operating—that is, production—and intent on financing—that is, raising money and meeting obligations. The sales leg—commercial management and public relations—has been a neglected, insecure one. But the stool has borne the weight upon it and the matter has had little thought.

Now comes a broader conception of the commercial opportunities and business obligations in the electrical industry. Bigger plans are forming. Greater expansion than ever is ahead. For the public *will* be served. And the development of a more general and intelligent equipment and electrification of buildings and industry, the development of a greater electrical merchandise market—in other words, the development of a more nearly universal application of electric service—presents an absorbing problem. More equipment and more appliances, which will use more energy and provide more service, are to be sold to industry, to agriculture and to the home. And naturally in each community the central station must lead in this work.

BUT this entire program means much more than just the selling of energy or appliances. The intelligent guidance and control of the expansion is the real issue. It is a problem of public relations, of community contacts. The need is thus for men rather than materials. And the important problem that confronts the president of the electric light and power company today is to strengthen the third leg of the stool by building up an adequate commercial organization that will go forward with the creative development of this greater market and service. Where he does not already exist in the president himself, the first need is for a commercial executive in every city who possesses the personality, the imagination and courage, the business experience and the commercial genius that will enable him to become the responsible head of this major activity of the business. In other words, the importance of the commercial division must be recognized, and it must be manned as effectively as are now the engineering and financial departments. The commercial executive of the central station is, moreover, the man who should make himself the head of the local electrical family, the leader and guide of all the electrical commercial activities in the town, working with a broad conception of the interest and service of the dealer, contractor, jobber and manufacturer as well as of his own company, to promote the expansion of the entire market for electric service and appliances. He should be a man of large caliber, a natural leader, able to win wide popularity without the sacrifice of proper dignity, amply qualified to take a prominent position among the influential business men of the community.

IT HAS long been customary for large and successful manufacturing enterprises to organize their personnel into these three departments of finance, production and sales. The problem of the central-station company is very similar, and the complete commercial function, embracing public and industry relations, customer contacts, publicity and selling, appears to be of sufficient magnitude to warrant its being headed, in the larger companies, by a "vice-president in charge of sales." In smaller organizations there should be a man no less appropriately titled and qualified to build sales and good will for the electrical industry.

Chief executives of central stations today can scarcely make any one move which will ultimately mean so much to the success of their business as to establish, where it has not already been done, commercial and public relations executives with the authority and support that will enable them enthusiastically and intelligently to develop the expansion of the industry. They will do this broadly in the public interest. Complete electric service will be brought into universal use, and the time to make adequate preparation is not some day—but now.

# George Edward Miller

*An exponent of the doctrine of a broad spirit of co-operation in business building for central stations.*

THE city of Cleveland has long been rated as one of the most advanced centers of electrical development. As the home of an exceptionally enterprising central-station company and a large and very active group of electrical manufacturers, it early became the source of much of the promotional activity of the electrical industry, a proving ground for many new ideas in electrical development. The Cleveland Electric Illuminating Company has been the moving spirit throughout this interesting evolution and finally itself withdrew from the sale of appliances, with the idea of encouraging the local electrical merchants.

For the last twelve years the executive direction of electrical development in Cleveland has been in the hands of George E. Miller, sales manager of the Illuminating company. Possessing rare business judgment and tact, he has functioned in an advisory and co-operative capacity, but in effect he has been placed in the position of an active sales manager for the local electrical family. He was the first president of the Cleveland Electrical League and has devoted much of his time and energy through these years to planning and making possible the broad advancement of the electrical idea in Cleveland and the development of a greater prosperity for the electrical business there.

Mr. Miller was born on a farm near Weldon Spring, Mo., in 1872. He was graduated from the State University at Rolla, Mo., in 1895 and for two years was assistant instructor in the civil engineering department of its School of Mines and Metallurgy. For a time he was engaged in consulting and designing electric light and waterworks plants in Middle West states.

But the problems of market development appealed to him very strongly, and in 1899 he became a sales engineer in the St. Louis office of the Westinghouse Electric & Manufacturing Company. A year later he was transferred to the Westinghouse headquarters at Pittsburgh, and for a period of seven years he engaged in sales work and confidential activities for the vice-president. He was assigned to the Cleveland district office in July, 1907. This brought him into close contact with the fascinating opportunities for market building that lie in the field of co-operation between the central-station company and the local electrical family of any community. He decided four years later to enter utility commercial work and joined the Cleveland Electric Illuminating Company, where he has won for himself a national reputation as one of the foremost utility sales managers of the day.

## Rendering Service a Business for Engineers

THROUGH his knowledge and training the engineer is particularly fitted to render service for the public welfare; but, being largely a creature of tradition, he is inclined to be exasperated by incompetence and ignorance and to fail to grasp the significance of facts not related to engineering. He looks upon commercial activities with distaste, not infrequently labeling business a "money-grabbing game." What the engineer fails to realize is that conditions now existing in our industrial civilization require his services, that he is under a heavy obligation to improve the civilization his engineering activities have produced, and that the only possible outlet for such services is through business channels. Engineering activities are really business activities, and the only touch with the public that can be maintained by the engineer is through the business contacts of his engineering operations.

The best salesman is the man who knows his product, and the engineers, therefore, should sell engineering service to the public if they are to develop and become an agency for the improvement of the national life. There is too much loose talking about water powers, transportation facilities, aviation, radio and other engineering subjects by politicians, lawyers, business men, economists and village gossips. If their imaginations are allowed to run wild, such men will hypnotize themselves into believing that their conjectures are facts. This is all wrong. Engineers must become publicists and must bring home the engineering side of these things to the public as business facts. Every engineering argument can be reduced to an economic fact or phrased in a popular manner which can be grasped by the public. If put forth by men who know whereof they speak and who are capable of stating it in a way dictated by business sense and a knowledge of mass psychology, these statements will carry conviction and belief.

## Petersen Coil Limited in Its Application

WIDELY different impressions have been left in the minds of engineers who attended the Pittsburgh convention of the American Institute of Electrical Engineers regarding the desirability of the Petersen grounding reactor. Some engineers, and possibly the majority, believe that the Petersen coil is a dead issue and has no application. Others quite as confidently believe that it can be adapted to any transmission system of moderate voltage.

The latter group are evidently impressed with the fact that the Petersen coil installation on the Alabama Power Company's system performed its function satisfactorily in 166 out of 168 cases of operation. While it was brought out in the discussion that the Petersen coil in this installation had to be short-circuited during switching operations to avoid producing severe voltage surges, it was not sufficiently emphasized that a still more practical disadvantage is the necessity of adjusting the reactor for every change in line conditions. If some simple scheme can be developed which will readily and quickly adjust the Petersen coil taps to the capacitance of the line which it is protecting, both these disadvantages will largely be eliminated and its field of application extended. Until that time it appears that the application of the Petersen coil will be limited to moderate-voltage branch lines.

## Why Not Centralize Experimentation in Station Design?

IT TAKES courage to be a pioneer in power-station design under existing conditions even though the economic prizes in prospect are unusually attractive. The rapid increase in the demand for power, the size of stations under consideration and the enormous investment required to build a modern station place a premium on conservatism and make reliability the governing element in design. Yet we find many stations under way which incorporate very radical departures in design principles, differ widely in their design details and involve experimentation and untried practice.

This fact is an indication of the courageous and forward-looking thinking prevalent in the central-station industry, which will surely achieve beneficial results. Yet a glance over the designs for contemplated stations shows a startling amount of variation in practice and a great amount of duplication in experimental work. Even though powdered fuel is adopted for many new stations, investigation shows that data for large boiler units are missing and that a great deal of experimentation will be necessary before the new stations operate satisfactorily. Even greater differences in practice and greater dearth of actual data are found in other contemplated practices. For example, one group of engineers enthusiastically plans several stations using reheated steam; another group advocates air preheating and cannot "find" economizers; still another group uses specially designed economizers and condensers and an unusual scheme for heat balancing. On top of all this stations are planned for the use of steam pressures of 375, 550, 1,200 and even 3,000 lb., with steam temperatures ranging up to 900 deg. F. No new basic theory has been developed which would prompt these designs; no great quantity of field data has been obtained, nor has there been any outstanding improvement in equipment recently. The wide adoption of new designs must therefore be largely a psychological reaction to the unprecedented demand for power, the good money market and the healthy state of the industry, coupled with a supreme confidence that the technical problems involved will be conquered.

While this general movement is fundamentally sound

and will prove its value, yet it does seem that there is a good opportunity to achieve the same results in a less expensive and less hazardous way. Why not centralize the equipment and personnel needed to determine experimentally the commercial limits of pressure and temperature and to obtain real data on preheating, economizers, steam reheating, condensers, burning of pulverized fuel and so forth? Would this not seem a logical way to approach an engineering problem of this importance and size? Most of these questions will have to be decided by getting data on installations of magnitude and by doing a great deal of research work, and the centralization plan would be the cheapest way to insure results, to say nothing of eliminating the duplication, false designs and operating hazards that may occur in the individual installations.

## Rating of Insulator Should Be Guide to Selection

FROM the user's standpoint the nominal line-voltage method of rating pin-type insulators has always been a source of confusion. One reason is that the ratings, as between different manufacturers, have not been uniform, and, what is more important, no rating of this character can take into consideration all the factors entering into the selection of insulators for any given situation. An insulator of a given nominal line-voltage rating may be good on one extreme for a line voltage of more than its rating. This condition occurs in some sections of the dry desert country of the West. On the other extreme a line operating at the same voltage may demand an insulator, rated on the same basis, at as high as eight or ten times the line voltage. This occurs where salt or chemical fogs or like conditions put a conducting deposit on the insulators. Between these two extremes lie the long list of system and climatic conditions which call for a selection that has little direct relation to the nominal voltage of the transmission line.

As a result of these conditions the more experienced designers have for a number of years been selecting pin-type insulators largely on dry-flashover voltages after careful consideration of the conditions under which the insulators are to be used. The less experienced designers have been placing dependence on the catalog ratings and then paying for the mistakes of selection in operating trouble and expense.

A demand, voiced by a few individual engineers, in addition to the action taken at the Pacific Coast convention of the American Institute of Electrical Engineers at Portland in 1920, was for a complete standard specification for insulators. When the committee came to examine the manufacturing situation, it was apparent that ceramic engineers have not yet had sufficient experience to write a standard specification for high-tension porcelain and that such a specification would be likely to prove a hindrance rather than a help. While the users were struggling with the rating situation, the manufacturers were struggling with a demand for tests and for compliance with specifications that were almost as numerous as the engineers responsible for the selection of insulators. Transmission-line designers were also embarrassed by the lack of specifications recognized as standards and the consequent uncertainty as to just how any two test voltages for different insulators could be compared. Some of the demands for acceptance tests were largely of the freak class, and the general result of the condition was an economic waste that could be obviated if a standard for design and factory testing could be devised. Since the standardization of the entire insulator specifications could not be undertaken, the committee devoted its attention to clearing up the two conditions which seemed the most embarrassing and that, from a practical standpoint, could most easily be met.

At the Pittsburgh meeting last month the committee presented a recommendation for the standardization of ratings on the basis of dry-flashover voltage, at the same time recommending a standard set of both dry and wet flashover tests. Any discussion of the proposed standards should proceed with a knowledge of the past work and should be devoted to determining constructively whether the committee has presented material that will really clear up the two conditions mentioned. On the one hand, will the designer be enabled, with the proposed rating, more intelligently to select the pin-type insulator he needs and, on the other hand, will the manufacturer be able to put his production processes on a more satisfactory basis and devote less energy to meeting half-baked ideas as to the proper tests to which pin-type and also suspension insulators are to be submitted for acceptance? If this can be done, he will receive more time to work out improvements in insulator design and manufacture. Complete standardization will have to be a step-by-step process based on the development of the art and the economics of insulator production.

## Non-Fading Light Needed to Preserve Colors

THERE are numberless examples of paintings which have faded beyond all semblance of their pristine selves. Very serious loss of color has taken place in many museum specimens which it was imperative to preserve as nearly as possible in their original state. In an endeavor to combat this deterioration Sir Sydney Harmer of the British Museum has within the last few years conducted a long series of experiments to determine the character of color changes produced by the exposure of pigments to sunlight or other light, the cause of these color changes in so far as it may be ascertainable, and particularly the possible remedies. The experiments were made by exposing pigmented and other objects under plain and tinted glasses with a control series under black glass, the exposure lasting for several years. The screening glasses covered a range from practically light window glass to a strongly absorbing glass similar to what used to be known as Euphos ordinary yellow green, cutting off all the ultraviolet and most of the violet and blue. This last-named glass had decidedly too strong a color to be a satisfactory permanent housing. Years before this same ground had been, for the same good purpose, pretty thoroughly explored by Dr. Russell and Sir William Abney.

The first fact which was clearly established was that, on the whole, fading from the action of light does not ordinarily take place in the absence of oxygen and moisture. This immunity probably does not extend to some of the very fugitive dyes like erythrosine, but the relation is generally true that where there is no oxygen and no water there is no fading. Moreover, as

might be anticipated from our general knowledge of photochemical reactions, the strongest fading effects were produced by direct sunlight, which was at least a score of times more injurious than the strong devised daylight. The control experiments, which freely let through a large part of the heat associated with the illumination, showed plainly that the effect of heat as such was substantially negligible.

Fading due to artificial electric light was much less than even with devised daylight—about one-sixth as much according to the experiments—the electric light used for the comparison being a powerful gas-filled incandescent lamp. Such a lamp is by no means free from ultra-violet radiation; hence there is the probability that a toning screen which would hold down the radiation on objects to something substantially within the limits of the visible spectrum would be of material assistance in still further preventing fading. Indeed, artificial daylight, when not abnormally rich in blue, gives promise of displaying colored objects as in a museum to better advantage in many respects than natural daylight. However, one must remember that while a great deal of photochemical activity has been charged up to the ultra-violet light, pretty nearly every part of the spectrum has under favorable circumstances a chemical effect upon something.

From a practical standpoint it would seem to be worth while to work out a source of non-fading light and then take up wherever possible the additional problem of preserving valuable objects with a still greater probability of success by sealing them from the air. There is probably no such thing as absolute prevention of all fading, but if the danger could be put far off down the centuries by means which now can be easily applied the end would seem well worth the effort.

## Modulated High-Frequency Telephony Over Transmission Systems

INTERCOMMUNICATION between substations and other strategic points on a transmission system and its distributing center or generating stations has always been more or less troublesome. In the early days, when transmission lines were short and the energy sent over the lines moderate, it was no difficult matter to string telephone lines as transposed metallic circuits below the power lines and to obtain reasonably good and reliable results. Sufficiently accurate transposition was, however, not always easy, and hearing was somewhat interfered with by the effect of leaks. Moreover, the line ran a risk of contact with the transmission circuits through a break in the latter. None the less, when most circuits were on wooden poles and the duty comparatively light the telephone line got on fairly well.

Today, with very long transmission lines carrying great amounts of energy and strung for the most part on steel poles or towers, the erection and maintenance of a first-class communication system is very far from easy. All sorts of protection have to be used both for the safety of operators and to guard against interruption of communications in case a surge starts on the power line. When everything is in order good results may be obtained over long distances, but abnormal operating conditions will very easily put the line out of service at just the time when it is most needed. In a few instances separate pole lines on the same right-of-way have been used for the telephonic communication, but this is such an outrageously expensive proposition both in first cost and maintenance that it is not likely to become popular.

Recently a good deal of interest has been excited in radio communication, particularly the variety of it somewhat loosely known as "wired wireless." In point of fact this is nothing but telephony by modulated high-frequency currents, which in this case have their locus on the transmission lines to which the oscillations are communicated instead of being in the free ether customarily employed for radio. A good many attempts have been made by central-station companies and others to utilize this particular variety of telephony on a considerable scale. Without wishing to be censorious of a new development just finding its application, considerable is still to be learned and accomplished before it can be adopted as an emergency means of communication with any assurance. It is encouraging, however, to see so many companies willing to do a little pioneering and experimenting in this connection. Out of experiences like those related in this issue and that for April 21 should come knowledge which will enable the manufacturers' development departments to put in installations of greater reliability.

Actual tests reported in the April 21 issue show what in fact might have been anticipated—that the efficiency of the power line as a carrier for extremely high-frequency oscillations depends in very large measure on the electromagnetic properties of the system considered as a high-frequency proposition. It is not surprising, therefore, to learn, first, that the frequencies desirable on the ordinary transmission system for wave telephony are comparatively low, and that there is a marked preference on any given system for certain groups of low frequencies. In one case which was well investigated the shortest wave length by which transmission was well effected was about 2,000 meters, with another useful range at say three times this wave length, and still another at about 18,000 meters. Near these points transmission was good, away from them bad and sometimes entirely ineffective. This may mean that there are resonant frequencies on the system which virtually form short circuits for oscillations of most wave lengths, or that impedances of equally bad effect may turn up.

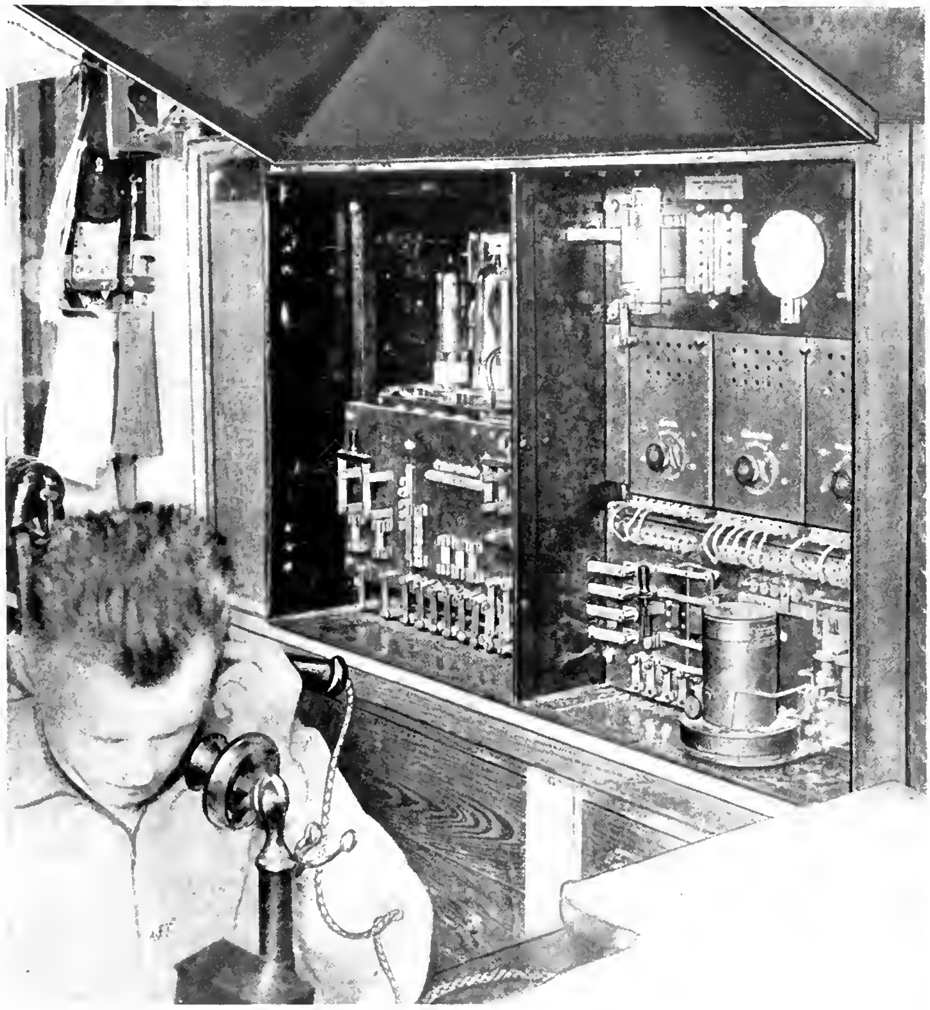
As might be expected, the scheme is interfered with by surges, short circuits and even the effect of switching. In fact, it should be easily seen that anything of this kind is likely greatly to upset the balance of the high-frequency system. Further trouble has been encountered from "spitting" insulators, which, of course, means variable leakage with all that that implies, and similarly electrolytic lightning arresters are likely to upset the successful operation of the system.

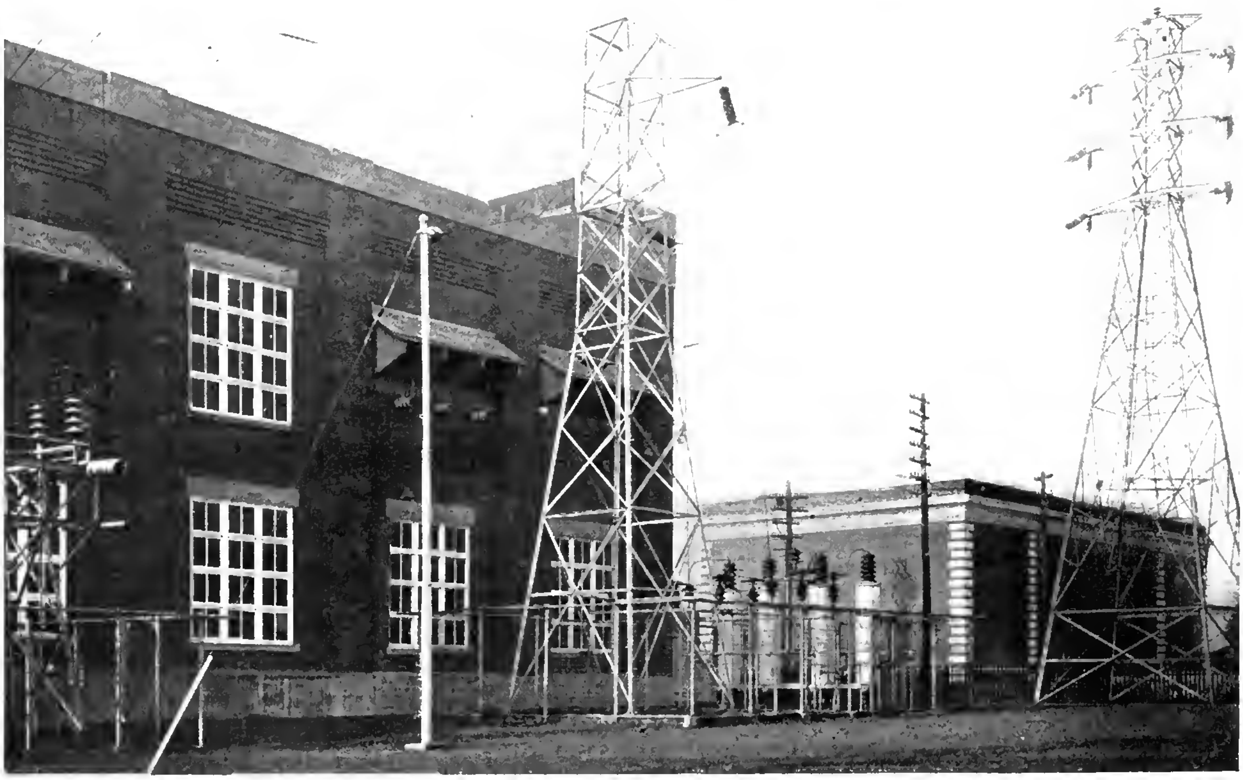
Doubtless, one factor in the successful operation of the Baltimore-Holtwood system, reported in this issue, is the simplicity of the transmission lines—that is, a single line without taps. This is in somewhat sharp contrast to the complicated system of the Duquesne Light Company, whose experiences were recorded in the April 21 issue.

It remains to be seen how far "wired wireless" can be used in a general way, although at present it may surely be said to be promising. Beyond all this comes the ordinary wave telephony, which has troubles of its own and plenty of them, but which may still "make good" over ordinary transmission system distances. It also seems likely that recent improvements may help the situation very materially so far as ordinary radio is concerned.

# Load Dispatching by Wired Wireless

IN ANY new development or application it is nothing unusual for various obstacles to arise. To a limited extent this has occurred with the application of carrier-current telephony to load dispatching and interstation communication. Remarkable strides have been made already by manufacturers in ironing out the obstacles, but further progress will be made in proportion as the operating companies exchange experiences with their fellow companies and manufacturers. Experiences of the Duquesne Light Company appeared in the April 21 issue of ELECTRICAL WORLD, and in this issue are presented those of the Pennsylvania Water & Power Company. One transmitting and receiving set is shown at the right and the line coupling below.





# Baltimore-Holtwood Carrier Current Giving Excellent Service

### Tested Under Service Conditions to Determine the Effect of Grounding Lines, Severity of Ground Currents, Charging Lightning Arresters, Nature of Coupling, Etc.—Three Months' Operation Entirely Successful

SEEKING some reliable means of assuring telephone communication between its Holtwood (Pa.) generating station and its main distributing substation at Baltimore,* the Pennsylvania Water & Power Company has installed and tested a carrier-current telephone outfit. It has been in operation since the beginning of the year and, according to tests and the experience of the operators, it is entirely successful—so much so that similar facilities for communication are contemplated between the generating station and the Lancaster (Pa.) substation.

In the past telephone communication between these points has been conducted solely over two physical wire circuits consisting of No. 9 B. & S. copper wires supported on wooden poles midway between the two tower lines connecting these points. These physical telephone circuits have provided good service except in cases of ground current and lightning surges. The need of supplementing these circuits by some other means of communication was emphasized, however, on July 25, 1921, when wire communication between Holtwood and Baltimore was totally interrupted for more than seven minutes owing to the failure of the telephone circuits. Prompted by this occurrence, General Electric carrier-current equipment was installed, using the high-voltage circuit as a guiding medium for transmission of speech. Tests were conducted to compare the operation and reliability of the carrier-current equipment with the physical-circuit telephones under service conditions involving grounds on the circuits at various points, ground current between stations, charging of lightning arresters and different degrees of carrier-current coupling.

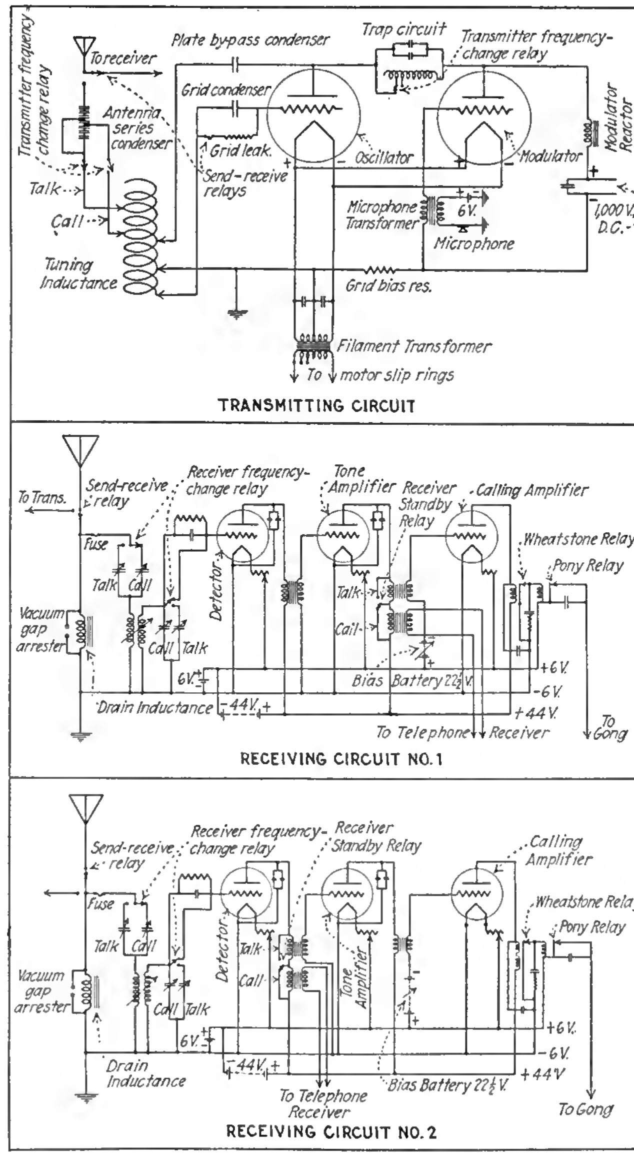
#### NATURE OF EQUIPMENT USED

The carrier-current equipment installed provides for calling and talking, but transmission of speech or call signals can be carried on in one direction only at a time. A carrier current provides means of transmitting speech and call signals, the calling and talking carrier frequencies being approximately 16,000 cycles and 12,000 cycles respectively

Modulation is accomplished by means of the well-known constant-current system. The calling and talking frequencies are separated by a frequency-change relay operated by a key on the telephone stand. This relay selects the taps on the tuning inductance, antenna series condenser and trap circuit corresponding to the talking or calling frequencies. Power for operating the small motor-generator set is received from the control battery at the station, and energy for lighting the filaments of the tubes is obtained from slip rings on the motor at 154 volts, 30 cycles, and is transformed to 10 volts, 6.5 amp. for the filaments.

As in the transmitting set, relays are employed to

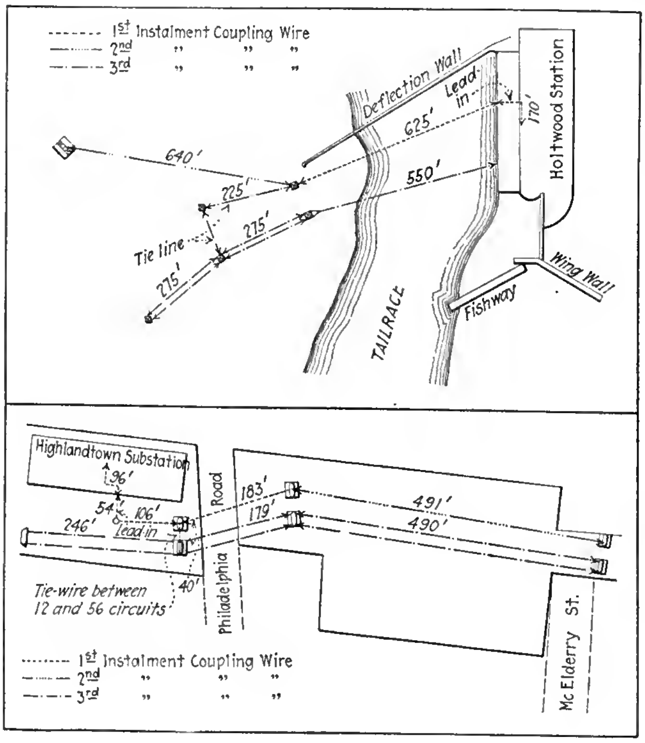
*Approximately 40 miles between stations.



TRANSMITTING-SET CIRCUITS AND TWO RECEIVING CIRCUITS WHICH WERE TRIED

tune the receiving set to the talking or calling frequencies, being operated by raising or lowering the telephone switch hook. The last tube is connected to a calling relay which operates a pony relay to ring a call bell. These call relays are disconnected from the circuit when the receiver is taken from the hook, and at the same time the receiver is automatically connected in the circuit.

Coupling of the transmitting and receiving sets with the transmission line is accomplished by utilizing the



LINE COUPLINGS AT HOLTWOOD AND HIGHLANDTOWN TERMINALS

existing ground wires over the circuit, sections thereof being insulated from the remainder of the ground wire and from the towers and brought to the sets by lead-in wires. The method of coupling is indicated in two of the accompanying illustrations. The coupling wire at the generating station and the wire at the substation end of the line differ in length and have been added to since the equipment was originally installed.

Tests were made under three different conditions: (1) With original coupling wires over circuits Nos. 1 and 2; these were 290 ft. at the Baltimore end and 625 ft. at the Holtwood end. (2) With lengthened coupling wires over circuits Nos. 1 and 2, consisting of 780 ft. at Baltimore and 1,265 ft. at Holtwood. (3) With the coupling wires of condition No. 2 in parallel with coupling wires over circuits Nos. 5 and 6.

The lead-in at Holtwood is 170 ft. in length and that at Baltimore is 150 ft. At Baltimore there are two ground wires on circuits Nos. 5 and 6, both of which are used as coupling wires, while at Holtwood the tailrace span now used as a coupling wire consists of a single wire. The wires are tied together between towers so that an H-shaped coupling is formed. The coupling wires consist of seven-strand $\frac{3}{8}$-in. steel cable.

Using the coupling wires as originally installed over circuits Nos. 1 and 2 (condition No. 1), the transmitters and receivers at Holtwood and Baltimore were adjusted to the best conditions for operation. Receiving condition No. 3 was used both at Holtwood and Baltimore. The quality of the speech was excellent. However, two limitations to the use of the short coupling wire became evident: (1) The talk and call frequencies could not be separated far enough to prevent the talk frequency from ringing the call bell, and (2) the frequency of the carrier could not be lowered to a value which would prevent interference from commercial long-wave radio stations.

Using the same coupling, a series of grounding tests were conducted on circuits Nos. 1 and 2. The procedure followed was to take the circuits out of service and ground a number of phases at Holtwood or Baltimore, or at both stations as desired, and to attempt conversation and ringing over the carrier.

The results from this test show that under the conditions employed, communication was impossible in either direction with circuits Nos. 1 and 2 grounded at both Holtwood and Baltimore. However, with one phase ungrounded entirely and the other five conductors grounded at both ends communication became possible. With one circuit ungrounded at both ends and the other circuit still grounded at both ends talking and calling became entirely normal.

### Coupling Increased

As a result of the difficulties previously mentioned, the coupling over circuits Nos. 1 and 2 was lengthened both at Holtwood and Baltimore. This necessitated a retuning of both sets to allow for the increased capacity

and inductance due to the additional wire. Receiving connection No. 3 was still used at both stations. With circuits Nos. 1 and 2 carrying load under normal conditions, reception was very loud and clear. The quality of speech, however, was not so good as with the shorter coupling wire, since the signal strength was increased beyond the limit of some of the apparatus. Furthermore, the 25-cycle hum was increased somewhat, as would be expected. With the longer coupling it was found possible to separate the call and talk frequencies so that there was no interference between the two, and in addition code interference was avoided. Frequency measurements with a wave meter at Baltimore determined the call frequency as 16,200 cycles and the talk frequency as 12,400 cycles (wave lengths, 18,500 m. and 24,200 m. respectively).

### Compare Line and Carrier Telephone

In an attempt to reproduce the conditions which caused total interruption of the physical telephone circuit on July 25, 1921, eight ground current tests were made and the behavior of the carrier-current equipment was carefully observed and compared with that of the physical lines. No. 1 generator and No. 1 transformer at Holtwood, with the transformer neutral grounded and the ground stack shunted, were connected to circuit No. 2. Phases B and C of this circuit were short-circuited and grounded at Baltimore, and phase A was left open. A separate exciter was used to control the generator voltage. Circuits Nos. 1, 5 and 6 were kept in service and carrying load.

The results of the tests with these conditions are arranged in condensed form in the accompanying table. With the neutral of the telephone-phantom transformers grounded at Holtwood and Baltimore, furnishing a metallic return for ground currents, the physical lines became useless as soon as the ground current reached an appreciable value. The arresters flashed over at both ends of the line, causing very loud clicking in the telephones, which continued until the fuses blew at Baltimore. The carrier equipment was less seriously affected. The chief disturbance seemed to come from the periodic flashing over of the physical-line arresters, causing a clicking in the carrier receiver. This clicking ceased as soon as the fuses blew on the physical lines. Switching conversation could be carried on successfully in spite of the noise.

With the "disconnects" opened on the telephone lines and the lines short-circuited and grounded at both ends, little or no noise could be noticed in the receiver of the carrier equipment. This indicates that the noise in the carrier was largely due to interference from protective apparatus on the telephone lines.

The most serious trouble occurred when the phantom neutral at Baltimore was opened while that at Holtwood remained grounded. The carrier actually became so noisy that communication was impossible for about twenty or thirty seconds. However, this was due to the same cause. The noise ceased after arresters had failed and fuses at Baltimore had functioned.

Two ringing tests were made. Holtwood called Baltimore successfully, but when Baltimore attempted to call

Holtwood the Holtwood bell rang continuously. The test was repeated with both equipments in position to receive calls (that is, receivers on the hooks), and while there was no effect at Baltimore, the Holtwood bell rang intermittently.

A second series of grounding tests, more comprehensive than those made under condition No. 1, were made with the longer coupling over circuits Nos. 1 and 2. In certain of these tests grounds were made between terminals of the transmission lines as well as at the ends.

As in the previous grounding tests, satisfactory communication could not be obtained with circuits Nos. 1 and 2 grounded at both ends. Baltimore could consistently hear Holtwood, but the speech was too faint to be understandable. The test is of significance in showing that the longer coupling wire at Holtwood was a better transmitter than the shorter wire at Baltimore. With five phases grounded at both ends and one phase open throughout, talking was about two-thirds of normal strength in both directions. Ringing was possible in one direction only, but this was shown to be due to a slight misadjustment in tuning at Baltimore, since it was found that, after retuning, calls could be received in both directions satisfactorily. This test, together with a similar test made with the short coupling, pointed out the desirability of adding coupling wires over circuits Nos. 5 and 6 in addition to those over

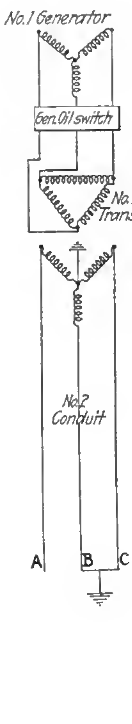
Hd., no damage. | Hd. bell rang intermittently. Hn. bell did not ring. |



No ground current. Ground switch accidentally left open at Hd.
NOTE:—Telephone bells rang until physical lines failed.

circuits Nos. 1 and 2, so as further to insure there being always one clear phase in the event of trouble on the circuits. Accordingly, coupling wires were added over circuits Nos. 5 and 6 at Holtwood and Baltimore and tied in with the coupling wires over circuits Nos. 1 and 2, forming an H-shaped coupling wire.

After the addition of coupling wires over circuits Nos. 5 and 6, the set was again retuned. The output to the coupling wire at Baltimore was then 0.35 amp. at the talking frequency and 0.36 amp. at the calling frequency. The output at Holtwood after retuning was 0.29 amp. on the talking frequency and 0.25 amp. on the calling frequency. With the new adjustment the speech was very loud but not modulated quite so well as in the two previous conditions. The voice had to be pitched to a low tone or speech was unintelligible. Furthermore, the 25-cycle hum was very loud. An attempt was made to lower the speech intensity to a comfortable value by introducing a resistance in series with the high-voltage generator field, thus lowering the plate voltage. This cleared up the speech to some extent, but interfered with calling. Consequently the receiving-set connections were changed to connection No. 2 in the accompanying diagram. This made some improvement in modulation of speech and practically eliminated the 25-cycle hum. Calling was satisfactory.

Only one grounding test was completed with this connection. All phases of circuits Nos. 1 and 2 were grounded at Holtwood and Baltimore. There seemed to be no noticeable difference in transmission, talking and calling being normal in both directions.

With the receiving connections just named, a test was made to determine the effect of lowering the input voltage to the motor-generator set. It was found that conversation could be carried on with a voltage as low as 140, while calling required a minimum of 180 volts input to the motor.

### Effect of Arrester Charging

For the purpose of observing the operation of the carrier equipment during arrester charging, a series of tests were conducted during the regular daily charging period in order to obtain actual operating conditions. Each arrester at both Holtwood and Baltimore (circuit No. 2 arrester at Baltimore out of service) was charged in the normal manner. Observations consisted of talking and listening at both stations, thus enabling each station to compare the intensity of the disturbance caused by the local arresters with that from the arresters at the other end of the transmission system. In addition, the effect of arrester charging on the call bell was noted at each end.

While the arrester gaps were closed, no disturbing noises were noticed, but a loud static discharge was heard each time an arrester gap was opened or closed. The intensity of this discharge was about twice as great at the station at which the arrester was charging as it was at the other station. Throughout the test speech could be understood satisfactorily at both Holtwood and Baltimore on account of the short duration of the discharge. However, if the discharge had continued an appreciable time, reception would have been practically impossible at the station at which the arrester was charging.

Charging of arresters at either Holtwood or Baltimore did not affect the Holtwood equipment with both receivers on the hooks in position to receive calls. At Baltimore, however, during charging at either station the bell gave short clicks each time an arrester gap was opened or closed.

A number of tests similar to those conducted on the carrier equipment were made on the physical lines during arrester charging. As before, observations consisted of talking and listening at both ends. The results obtained showed that there were no disturbing noises when the gaps were actually closed, but when the operator opened or closed the gaps a faint static discharge followed by a louder click was heard in the receiver. The intensity of this discharge was at all times much less than that heard over the carrier.

Observations made on the carrier equipment during sleet runs on the transmission systems—that is, a practice adopted during sleet storms to melt the sleet from the wires by circulating sufficient current through them to melt the sleet—showed that these runs in no way affected communication. Conversation was carried on with each of the four circuits on a sleet run. The physical circuits were also not affected during sleet runs.

### Radiation Negligible

Little or no radiation is to be expected from the carrier wave because of the low frequency employed and the close coupling with the circuits. On one occasion, however, it was reported at Holtwood that conversation had been overheard from the Holtwood station by a Westinghouse "type RC" receiving set in the clubhouse. This occurred during the period of adjustment with the original coupling wire. Since then no report of any reception of this character has been received. An attempt was made later to repeat the above experience with the present adjustments, but no conversation could be picked up. An attempt was also made to pick up signals using a number of single-circuit amateur receiving sets installed near circuits Nos. 3 and 4 at Holtwood, but no reception was reported. However, in no case were the sets tuned to the wave length of the carrier, their range being limited to the broadcasting wave lengths.

### Carrier Current Meets Operating Requirements

As a result of these tests it was concluded that conversation and calling can be conducted in an entirely satisfactory manner over the carrier equipment for all conditions met in normal operation. With coupling on circuits Nos. 1, 2, 5 and 6 communication is practically unaffected by grounding circuits Nos. 1 and 2 at both ends. Previous tests (those made with one coupling wire over circuits Nos. 1 and 2) indicate that when using the present coupling wire over all four circuits conversation would be satisfactory with but one phase of the four circuits free from grounds. Conversation can be carried on with the carrier under conditions which render the physical lines totally inoperative as demonstrated by the ground-current tests.

No final conclusions can be drawn at this time as to the comparative operation under all conditions of the carrier equipment and the physical lines, because of the short time the former has been in service. Further observations will be made during heavy static and at times of electrical storms. A careful check is being made of day-to-day operation to determine the effect of variation in weather conditions.

The foregoing information is based on tests made by J. E. Allen, chief of tests for the Pennsylvania Water & Power Company.

# Lead Resistance for Current Transformers*

Advocates at Least 0.1 Ohm of Non-Reactive Resistance in Leads of All Current Transformers Subject to Precision Tests

By F. B. Silsbee
Physicist, Bureau of Standards, Washington, D. C.

FROM the time of the first introduction of current transformers the doctrine which has been preached continually by professors, engineers, manufacturers and every one else has been "keep the secondary burden small if you want to obtain accuracy." Like any other good thing, this idea can be carried too far; hence this plea from the testing laboratory for "moderation in all things."

In the precise testing of a current transformer the methods used in any laboratory require the insertion into the secondary circuit of a certain amount of impedance. In the use of the comparison methods, where one transformer is compared with a standard, this impedance can be fairly small (0.02 ohm), and can often be neglected. In the more precise "absolute" methods which test a single transformer, however, the impedance is necessarily large and is often from 0.1 ohm to 0.2 ohm.

## Problems in Precision Testing

If the user of the transformers requests a test with a burden consisting of, say, an ammeter, wattmeter and 0.1 ohm in leads, then all is well; for it is very easy for the laboratory to connect the instruments in the circuit with short, heavy leads and substitute the testing circuit in place of the 0.1-ohm leads. Even if the burden is specified as an instrument having 1 millihenry and 0.4 ohm with 0.01 ohm leads, the laboratory can still "beat the game" by substituting an inductor having the desired 1 millihenry and only 0.2 ohm, thus gaining a margin of 0.21 ohm for the testing circuit. This is not perfectly satisfactory, however, since (1) the impedance of the actual instruments may vary slightly from the values stated (which are usually obtained from the manufacturer as representative of the type), (2) the reactance of the instruments often changes somewhat from one point of the scale to another, and (3) if the magnetic circuit of the instrument contains iron, the reactance will vary with the current and hence the air-core coil of fixed value is not equivalent to the actual instrument.

The rub comes, however, when the user requests a burden of which the time constant (ratio of inductance to resistance) is greater than the value (0.005 second) which can be obtained with air-core coils of moderate size or in which the total resistance of the burden is less than 0.1 ohm. "One watt-hour meter with 3 ft. of No. 10 B. & S. gage (i.e., 0.003-ohm) leads" is a typical example of such a burden.

What can the laboratory do in such a case? It is theoretically possible to test a current transformer with zero burden, but to adapt the apparatus for such a method is very impracticable. Actually in such a case the laboratory now does double work. It first makes a test with the least resistance it can use—i.e., with a burden of "one watt-hour meter plus 0.10 ohm." It then repeats the test, using "one watt-hour meter plus 0.197 ohm." If the ratio and phase angle vary linearly with resistance in the secondary (which is roughly true), then an extrapolation gives the desired data.

The purpose of this article is to suggest that instead of doing this, the customer should always include a non-reactive resistance as great as 0.1 ohm, with transformers which are likely to be submitted for precise test.

A consideration of the objections that can be offered to the adoption of such a practice in various cases follows:

Current transformers submitted for laboratory tests may be classified according to the purpose for which they are used, thus:

A. *For special measurements of the highest precision.*—Here the transformer is always first tested with the actual burden with which it is to be used and the necessary corrections to its ratio and phase angle are applied in working up the results of the measurements made with it.

B. *For general use under conditions which cannot be foretold, but which may require high precision.*—Here the test is made with the burden which will most probably be used later and the corrections are often but not always applied in the actual use of the transformer later.

C. *For work of less precision.*—Here a test is needed to make sure that the performance does not depart excessively from the theoretical. Only the nominal value of the ratio is used in the future use of such transformers.

D. *For a type test.*—Here the test is desired to indicate the relative merit of the particular type of transformer relative to other types. The results of the test will probably not be utilized in actual measurements made with the transformer later.

Besides these four classes, there are the great body of transformers which have never been and never will be subjected to laboratory test and which need not be considered.

For transformers of class D there is obviously no objection to the insertion of an additional 0.1 ohm in the burden in all cases, since the comparison of types is not affected thereby. For class A also the presence of the 0.1 ohm will not increase the labor of observation or computation, except for the purely physical labor of seeing that the 0.1-ohm coil is correctly inserted. Any such difficulty is more than offset by the fact that, when desired, the transformer can be used with the same correction table when 50 ft. away from the instruments if connected to them by No. 10 wire.

In cases B and C, however, the question arises whether or not the insertion of the 0.1 ohm increases the ratio and phase-angle errors of the transformer. Such an increase in error might appear either as a greater departure from the ideal, nominal ratio and zero-phase angle or as an increase in the variation in ratio and phase on passing from one value of current or burden to another value of current or burden. An examination of the magnitude of such effects is next in order.

## Errors Not Proportional to Burden

It is very natural, though erroneous, to consider that the errors in a current transformer are, at any rate roughly, proportional to the external secondary burden and that if one reduces his burden from 0.15 ohm to 0.05 ohm by eliminating lead resistance, he will cut his errors to one-third. The fallacy of this appears when one considers that the secondary winding has a resistance of several tenths of an ohm, to say nothing of its leakage reactance. The secondary resistance of an assortment of twenty-five current transformers selected at random varied from 0.158 ohm to 0.55 ohm, the average being 0.35 ohm.

*Published by permission of the Director of the Bureau of Standards of the United States Department of Commerce.

The reduction of the burden from 0.15 ohm to 0.05 ohm, therefore, on the average reduces the total resistance from 0.50 to 0.40 and probably reduces the errors to 80 per cent of their former value instead of dividing them by 3.

Actual data on a number of transformers tested at the Bureau of Standards during the past few years show that the change in ratio when 0.1 ohm is inserted in the secondary was in the worst case only 0.1 per cent at 5 amp. and 0.2 per cent at 0.5 amp. In most other cases, however, the changes were decidedly less and seldom exceeded 0.02 per cent. The same poor transformer showed a phase-angle change of 25 minutes when 0.1 ohm was added, but no other showed more than 2 minutes at full current or 6 minutes at 0.5 amp.

It appears from this that the errors introduced by using the nominal instead of the actual ratio of the transformer are only very slightly greater when a lead resistance of 0.1 ohm is used. Furthermore, fully 50 per cent (an actual count of transformers tested at the bureau showed 66 per cent) of transformers have ratios less than nominal, so that the chances are about even that the ratio of a given transformer will be improved rather than impaired by the insertion of resistance.

Similar data show that the changes in ratio and phase angle with current at a given frequency and burden are only very slightly affected by the addition of 0.1 ohm. The increase in the change in ratio is only a few parts in 10,000, and the increase in the change in phase angle is only a few minutes in most of the transformers.

The conclusion is thus reached that the practice of allowing at least 0.1 ohm of non-reactive resistance in the burdens of all current transformers which are likely to be submitted to precise tests is at once highly desirable in the testing and perfectly harmless in the use of the transformer.

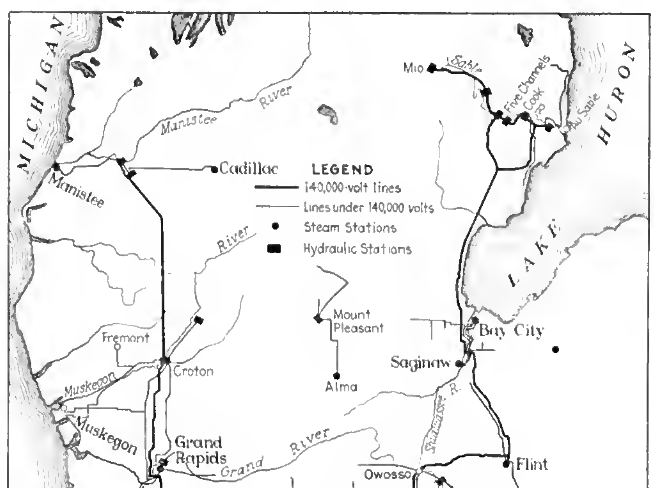
# Co-ordinating Steam and Hydro Operation

## Entire System Economy More Important than Individual Plant Economy—Must Keep Pace with Weather Conditions—Problem Is When to Use Steam and When to Use Hydro Equipment

By F. W. POLLOCK
*Consumers' Power Company, Jackson, Mich.*

OWING to the necessity of shifting loads on interconnected hydro-electric and steam plants in order to keep pace with weather conditions, to protect against line breakages and to improve power factor or voltage regulation, it is not always economical to operate stations at their highest individual efficiencies. If proper consideration be given to *system* economy, however, it may sometimes even pay to sacrifice individual plant economy.

The Consumers' system might be visualized in the shape of an enormous "U," formed by the 140-kv. transmission lines which convey energy from the Au Sable River on one side and the Manistee River on the other side of the state down to Battle Creek, which is the center of southern distribution. The principal sources of hydro-electric energy are at the extreme northern ends of the "U," while the large distribution centers are at the southern intersections of the two lines. This "U" is somewhat distorted as the transmission line connects with steam generating stations at Grand Rapids, Kalamazoo, Jackson, Flint, Saginaw and Bay City. Moreover, other hydraulic stations are connected by 40-kv., 70-kv. and 22-kv. transmission lines, which, along with the lower voltage circuits, complete the network for serving the people of Michigan.



THE "U" TRANSMISSION LINES OF THE CONSUMERS' POWER COMPANY

The maintaining of frequency and correct voltage, the question of power factor and the protection of service at different points are problems which become more complicated with long stretches of high-voltage transmission lines. Because of the fact that this system is a hydro-electric system and consequently somewhat dependent upon the ever-changing weather conditions, changes in methods of operation are often necessary over night. The yearly cycle of operation for the system is divided into four periods which follow the four seasons of the calendar year. This is indicated on the chart showing comparison of rainfall with hydraulic output. With the spring comes the break-up of the winter ice and snow, which, with the customary rains, results in a high-water period. Summer brings the hot, dry weather accompanied by drought, resulting in the low-water period of the system. The fall rains somewhat relieve the conditions of the summer, giving better water conditions. This allows the steam equipment of the system a breathing spell before the cold weather of the winter again freezes up the small creeks and river

tributaries, thereby cutting down the flow of water to a second low-water period.

But, one might ask, what has this to do with system efficiency? If the rivers of the state had an absolutely constant flow during the year, a scheme of operation could be devised which would attain to a high degree of efficiency, or at least one which would need little or no attention. This, however, is a dream of conditions which could exist only in an ideal climate. Plants must be designed to handle the largest possible percentage of water discharged during the high-water periods without having a great amount of capacity lying idle during the low-water periods. These plants must be operated on a basis which will give certain desired conditions at all points on the system, regardless of individual plant efficiency. The same holds true with steam-plant equipment. Sufficient installed capacity is necessary not only to handle the required portion of the load during the low-water periods, but enough to meet any emergency which might arise through the loss of a transmission artery from one of the northern rivers. Some steam plants are subjected to the same varying load conditions at times to obtain proper system conditions.

Some of the Consumers' Power Company steam and hydraulic plants are among the most efficient in operation. There are in all twenty-two hydro-electric plants supplying current for the system. These plants range in capacity from 150 kw. to 18,000 kw. and are tied into the transmission system at points greatly removed from each other. Many of these plants are operated at their most efficient point continuously throughout the year. They are operated at the most efficient governor-gate opening, and the headwater is not allowed to drop below certain limits. The length of operation on each unit varies with the river conditions, depending on the season of the year. With all units 100 per cent governor-gate opening is practiced during maximum water periods.

The Plainwell hydraulic station operates week after week during the low-water period on a governor-gate opening of 82 per cent. This is the most efficient point. The headwater does not fluctuate more than 0.2 ft. or 0.3 ft. from crest. There are three units of equal

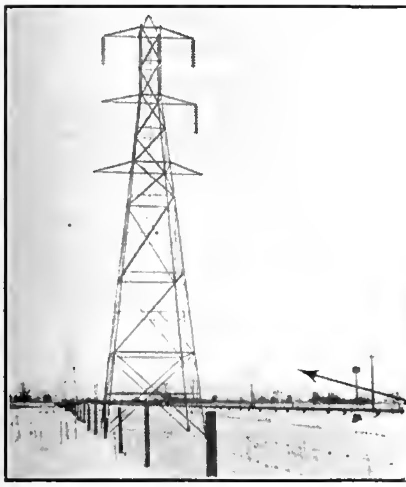
TWO FORMS OF RECORD FROM WHICH THE DAY-BY-DAY OPERATION OF THE CONSUMERS' POWER COMPANY STEAM AND HYDRO PLANTS IS DETERMINED

They contain the routine data on plant operation and conditions, both of water supply and the physical conditions of apparatus that can be operated.

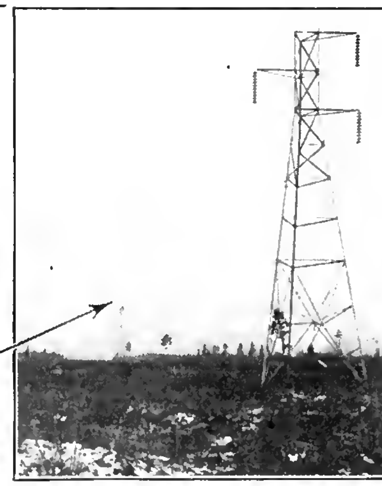
capacity in this plant. If the river flow is greater than one unit will handle, the headwater is allowed to gain with one unit in operation at 82 per cent governor until maximum elevation has been reached. A second unit is then placed on the line at 82 per cent governor opening and the headwater pulled down 0.3 ft. At this point one of the units is taken off and the headwater allowed to return to crest. The water is handled between these limits by the use of one, two or three machines, depending on the river conditions. In this way maximum efficiency is obtained.

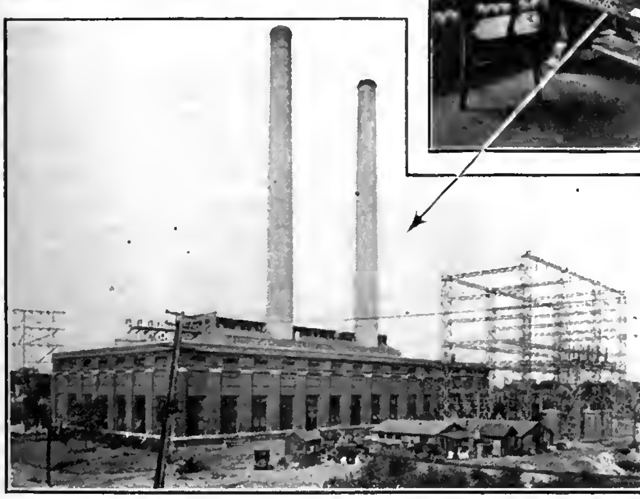
This scheme could not be applied throughout hydraulic operation, since it would necessitate an enlarged at crest, an excessive amount of fuel would be consumed at the steam plants during the day, making it necessary to waste water at night on the off-peak period.

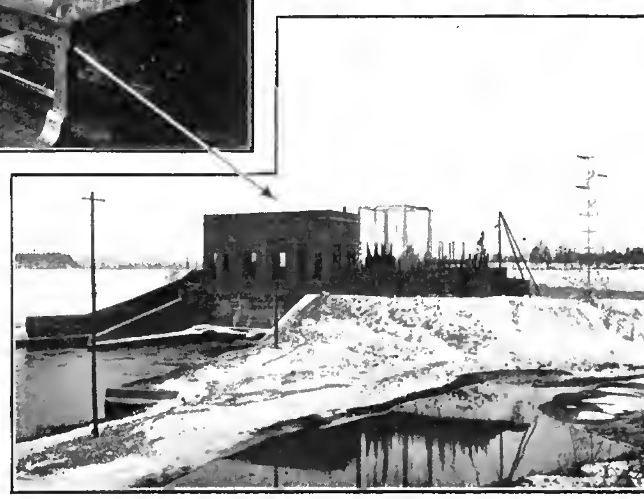
A compromise between these two possibilities results in better economy, which gives steam generation as near a constant daily load as possible for twenty-four hours. As the load comes on the system each morning it is picked up by the water stations, which are operated on efficient governor openings. One plant is known as a "regulating plant" and takes all the fluctuations in load. The load factor of this plant may be low at times since the load swings from no load to full plant capacity. The hydraulic stations accommodate the



STATION SWITCHING AND LINE CONTROL ARE SUPERVISED FROM THE SYSTEM OPERATOR'S DESK SHOWN IN THE CENTER







steam generation during the heavy-load period of the day and because there would not be sufficient load to accommodate the hydro plants during the off-peak period should several of them arrive at full head at the same time. The amount lost in fuel consumption and wasted water would prohibit this plan.

The ideal arrangement would be one which would give steam generation a straight-line curve twenty-four hours a day with a hydraulic plant operation on the plan mentioned above. As this is not possible because of the irregularity of the load, certain changes must be made affecting both steam and hydraulic stations. It must be decided what portion of the load will be carried on steam or water. If steam generation is reduced below a certain point, the system suffers by so lowering the headwater at the various hydraulic stations that inefficient operation results. On the other hand, if the headwater were continuously maintained load drop during the noon hour, and as fast as the power load drops off in the evening the hydraulic capacity is shut down, thereby allowing the ponds to fill up for the next day's operation.

During low-water periods when the river flow is very small it is primarily essential to keep the headwater of the various plants up to crest, since with low heads much additional steam is required to build the water level up again. If the plants are operated on low head, much is lost in efficiency. This problem is handled by the Consumers' Power Company as follows: Accurate records of each day's operation are kept both in the form of a summary of the day's operation and in hourly readings giving operating conditions at each generating plant. At midnight, when the total output figures are received from each plant by the load dispatcher on duty, a perusal of the headwater figures is made comparing them with those taken the previous night. This

shows at once whether there has been a loss or a gain in the headwater as a whole. It is then decided whether it is necessary to operate more or less steam on the coming day in order to bring the headwater back to its normal level.

Going further into the scheme of handling water conditions, the natural location of the hydraulic plants on the Au Sable River is also utilized. The Mio station is about 40 miles upstream from the other plants, which are closer together further down the river. This means that it takes approximately twenty hours for water discharged from the Mio plant to reach the other plants below. The water used one day at Mio is used the next day at the other four plants. Figures and charts have been devised so that it may be accurately determined at midnight from the previous day's output at Mio just what the value of water on the Au Sable River will be for the coming day and just what amount may be generated and full heads still be maintained.

As the total output on the system can be determined approximately, definite figures can be obtained on both steam and water. Thus there is no guesswork in cutting in boilers and placing steam units on the line.

Since certain boilers must be banked during the hours from 12 midnight to 5 a.m. in order to carry the daily maximum-demand load, the resulting steam plant efficiency is often decreased. Boiler operation at any steam plant on a poor load factor is seldom necessitated, with the exception of the operation of turbines at certain times as synchronous condensers to correct the power factor. This indicates one of the big problems in steam-plant operation. As an illustration of this point, during high-water periods it is often necessary to operate a steam plant with a large unit on a minimum load during the heavy-load period merely to maintain voltage. It is also true that an improved power factor would not entirely correct this condition since the capacity effect of the high-voltage line must be considered. But were the equipment such that a 100 per cent power factor might be obtained during the heavy load period, several units would still be required to operate as synchronous condensers during the off-peak period to compensate for transmission line capacity effect. This condition is not limited merely to one station on the transmission system, but involves great expense in order to keep conditions normal.

The operation of generating equipment for the correction of power factor is not limited to steam stations. Hydraulic capacity is sometimes operated during both heavy and light load periods daily in order to control voltage conditions at distribution centers. Several of the system hydraulic units are especially equipped for breaking the vacuum in order to be operated as synchronous condensers. Breaking the vacuum reduces the energy consumption, although approximately 200 kw. hourly is required to propel one of these units under such conditions.

Protection to service or insurance against interruption is very important and sometimes causes inefficient plant operation. When the system is visited by electrical or sleet storms, steam generating equipment must be placed on the line with sufficient boiler capacity to handle the load, even though this means backing down on the hydraulic plants and wasting water. If the storm is severe, boiler capacity is increased at all plants and steam units are often operated over long periods on light and inefficient loads so that they will be ready if any emergency arises. This represents a necessary expenditure to insure continuity of service.

## Business Activity Continues to Increase

INDEX figures upon which the "Electrical World Barometer of Business Conditions in the Electrical Industry" is based indicate another record operation within the industry during March. Pig-iron production, generally regarded as the most accurate single indicator of productive activity, made a new high record in that month, exceeding even the war-time production of December, 1918.

The basic data upon which the "Electrical World Barometer" is based indicate an increase of 4.4 points on the barometer scale as compared with February activities. During this interval the industry had grown 2.2 points, leaving a net increase in activity of 2.2 points on the barometer scale as compared with February. The electrical industry as a whole was operating in March at 27.9 points or per cent above what would have been the point of seasonal demand if growth in the industry had been normal. In February it was operating at 25.7 points or per cent above the point of normal demand.

# Industrial Electric Heat Applications—II*

## Types of Ovens and Their Field of Application—Limitations as Regards Duty and Temperature—Typical Installations Described and Operating Results Recorded—Advantages of Electric Heat Applications

By J. L. McK. YARDLEY
*General Engineer Westinghouse Electric & Manufacturing Company*

THERE are many types of ovens for industrial heating purposes and each has a well defined field for its application. In their use judgment must be exercised to secure best results and the proper type must be selected for the work under consideration. In order to bring out some of the commercial industrial ovens tabulations will be made with a brief comment on each type:

1. Electric range for the household. In connection with this application it is interesting to mention that over a test period of six months the average monthly power consumption for twenty-four families of four to six persons each was 100 kw.-hr.

2. Bread-baking ovens—reel type. One commercial size bakes 120 1-lb. loaves in a thirty-five-minute bake, which is equivalent to 175 loaves per hour. The input is 25 kw., or 7 lb. of bread are baked per kilowatt-hour. The loss to maintain the oven at the temperature required amounts to from 7 kw. to 8 kw. Larger and sectionalized types of ovens will be discussed later in their application to bread baking.

3. Enameling oven. These operate mostly at a temperature of 400 deg. to 500 deg. F., and there are many subdivisions: (a) The kiln type of oven, hand-operated, which produces 6 lb. to 8 lb. of work per kilowatt-hour; (b) the kiln type of oven, truck-operated, which produces 10 lb. to 12 lb. of work per kilowatt-hour; (c) the semi-continuous conveyor type, which produces 10 lb. to 12 lb. of work per kilowatt-hour; (d) the continuous conveyor type with air seal or exhaust fan, which produces 25 lb. to 30 lb. of work per kilowatt-hour.

In the making of bread, when the reel-type oven is used, the reel rotates and every loaf is baked equally by the heaters in the bottom of the oven. The oven, of course, is completely equipped with automatic control. In the continuous-conveyor type, which may make 1,200 loaves of bread per hour, the bread continually passes through the oven. The sectional type is made in several sizes, as from twenty to sixty loaves in a section. The idea is for the baker to buy one or two sections or hearths according to his needs and then add sections later as his bakery grows. Each section is heated from top and bottom and is provided with independent automatic control. The circuits are controlled by a motor-operated snap switch, which in turn is actuated by a small thermostat in the usual manner through the effect of furnace temperatures.

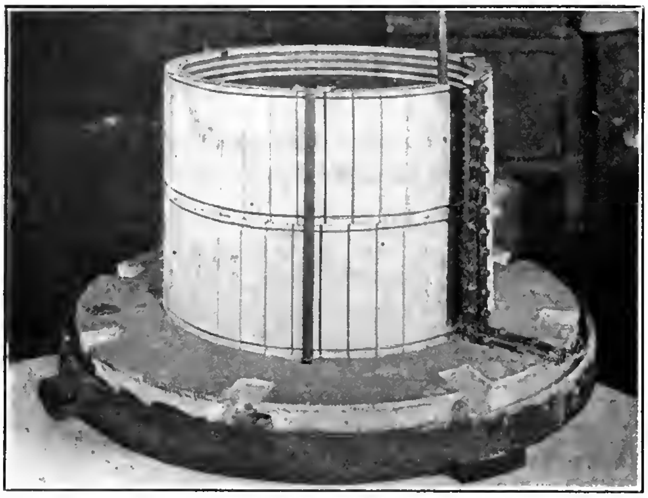
The heaters in the kiln-type oven are usually mounted in a vertical rather than in a horizontal position. The fresh air coming in at the top and passing through the heating elements at the side of the oven takes up the vapors which are heavier than air and is then exhausted from the bottom of the oven. This type of oven is largely used in the automobile industry and in furniture enameling. In some arrangements baffles with slits for admitting air to the interior of the oven are provided extending from the bottom to the top, and heaters are placed behind the baffles. The air inlets are placed beneath the heaters and the air passes up through the heaters and out through the slits into the baffles and into the oven. Fans for supplying the air are installed on the top of the oven.

A CONTINUOUS-CONVEYOR-TYPE OVEN FOR THE BUICK MOTOR COMPANY, DETROIT

Smaller ovens of the kiln type are made for hand operation. For example, a small oven with interior dimensions approximating 3 ft. x 3 ft. x 3 ft. is equipped with four 2½-kw. oven-type heaters and with the degree of heat insulation employed comes up to a temperature of 550 deg. F. in forty-five minutes. With power cut off, the temperature drops in two hours and ten minutes to 300 deg. F. Three kilowatts is required to maintain this temperature. The oven is designed to be operated with full automatic control at a temperature of 450 deg. F. The average thermal conductivity is approximately 0.8 B.t.u. per inch per square foot per degree Fahrenheit. Another size of hand-operated kiln type of oven in practical use has interior dimensions of approximately 4 ft. wide, 4 ft. high and 3 ft. deep.

Ovens of the semi-continuous conveyor type are being used extensively in the automobile industry, for example, at the Jordan Motor Company's plant, Cleveland. Here the work coming through the oven is allowed to

*This article is based on an address given by the author before the Toronto Section of the A. I. E. E. and the A. S. M. E.



ASSEMBLY OF HEATING ELEMENTS FOR 750-LB. SOLDER POT

hang on the conveyor over the drip tank. The work then passes into the oven and is baked while the conveyor over the drip tank is being filled again.

In the continuous-conveyor type, which is extensively used, the work goes through the oven continuously. One of the largest installations is at the Royal Typewriter Company's plant for the enameling of typewriter frames. Another large oven is installed at the works of the Buick Motor Car Company in Detroit. This oven has a capacity of 1,550 kw. The heating elements are all protected by screens. On the entering end they are mounted on the side walls and on the exit end on the floor. The reason for mounting them on the side walls at the entering end is that the work drips to some extent while passing through this part of the oven. Separate exhaust flues from the oven are brought outside to dissipate the noxious gases. This oven has been so satisfactory that it is now being practically duplicated in an extension of the same plant.

### SMALLER APPLICATIONS

The heating element in solder and babbitt pots is of considerably different construction from the others used. It may be operated up to a maximum of about 1,800 deg. F. and hence is applicable for work of 1,000 deg. F. or perhaps 1,200 deg. F. The 30-lb. preheat type of solder pot consists of a cast-iron shell lined with 1-in. molded insulation. The heating elements are directly underneath the cast-iron pot and are insulated by 1½ in. of "Nonpareil" brick. The brick is placed directly in contact with the heating elements and above the wire, so that all connections are amply protected. With terminals at the bottom it is well arranged for conduit attachment. About 1,300 watts is required to bring a 30-lb. charge to a temperature desired in fifty-five minutes; 650 watts is ample to keep the charge at temperature.

MOLTEN SALT IS USED IN THIS FURNACE AS THE RESISTOR ELEMENT; HEAT TREATMENT OF TOOLS TO 1,450 DEG. F. PRELIMINARY TO HARDENING

### HEAVY-DUTY-TYPE INDUSTRIAL FURNACES

The heavy-duty type of industrial furnace employs heating elements made of nickel chrome alloy. These elements are placed in grooved refractories or muffle plates of special composition which is a good dielectric and at the same time is a good conductor of heat. The heating elements, together with the grooved refractories, are held in position by T-shaped supports which fit loosely into recesses in the sides and roof of bricks. All terminals and connections between heating elements are made on the outside of the furnace. When operating on work the temperature of which is within 100 deg. or 200 deg. of that permissible for the elements, the intervening muffle plates are eliminated and the heating elements are arranged to radiate as directly as possible upon the work. It is obvious from the type of construction that there is no reasonable limit mechanically or electrically to the size to which this type of furnace may be built, and that it may have single or double doors. In the larger furnaces, of course, a substantial framework is required to carry the weight, and where heavy-duty work is involved the same attention to mechanical strength and ruggedness as in fuel-fired furnaces must be given.

The field for this type of furnace is very extended, being limited principally by the fact that the resistor itself cannot be operated for any appreciable length of time at more than 2,100 deg. F. An increasing number of these furnaces are being installed. Among others, arrangements have recently been made for the installation of the following, showing the variety of applications: A 60-kw. furnace for the treatment of wire, hardening at 1,650 deg. F., tempering at 900 deg. F.: a 210-kw. furnace for vitreous enameling at 1,800 deg. F.; a 33-kw. furnace for lead-bath treatment of steel saw blades at 1,600 deg. F.; a 220-kw. furnace of car-bottom type for the heat treatment of locomotive parts, piston rods, crankshafts, etc.; a 160-kw. pot and retort for the refining of sulphur, melting at 350 deg. F., distilling at 850 deg. F.

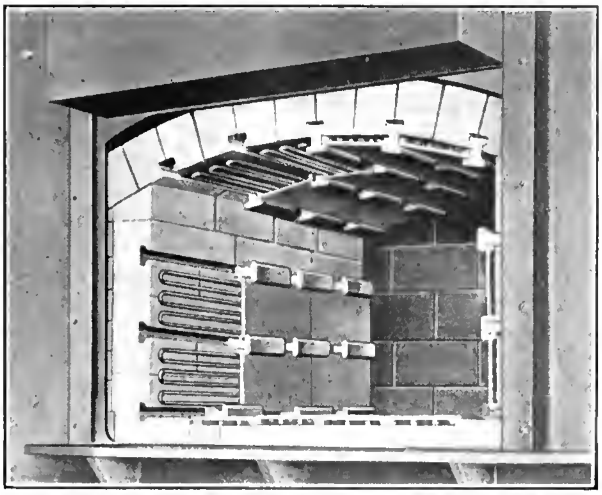
### FURNACE WITH MOLTEN-SALT RESISTOR ELEMENT

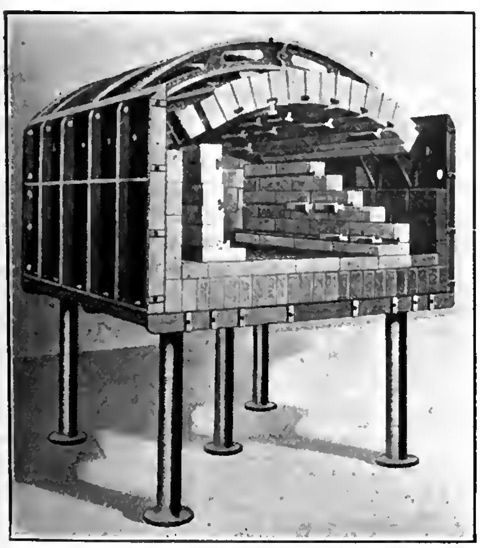
In the extensive search which led up to the development of the industrial heat-treating furnace of metallic resistor type, many other types of furnaces were, of course, tried out. It is of interest to refer to one or two of these which have given satisfactory results in practical operation.

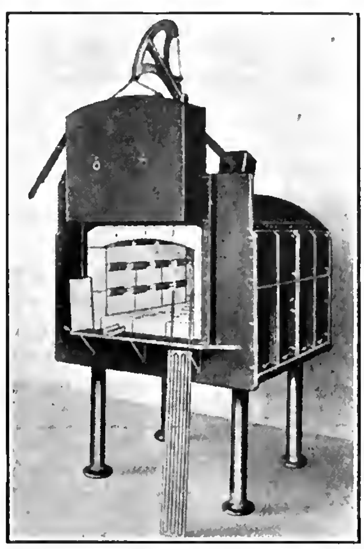
In one of these a molten salt is employed as the resistor element. The furnace is used for the heating of carbon-steel tools, reamers, etc., at a temperature of 1,450 deg. F. preliminary to hardening. It consists of a cast-iron cylinder 4 ft. high and 4 ft. in diameter,

open at the top and filled with firebrick, except for a well at the center 9 in. in diameter and 14 in. deep. Four blocks of carbon are built into the walls of the well, two on each side, and are connected to the electrical circuit. Power is supplied by a 24-kva., 30-volt to 60-volt transformer and switching panel. The furnace is started by connecting the carbon blocks by carbon rods. A mixture of dry barium chloride and sodium chloride is fed in and melted by the heat from the rods. The rods are then removed and the salts are kept molten at temperature by the passage of electric current through them. A number of advantages have been claimed for this type of furnace:

1. The temperature of heat treatment can be altered by varying the proportions of the salts employed.
2. For any given mixture of barium chloride and sodium chloride, or other salt, a practically uniform temperature is obtained.
3. The metal under treatment is in no danger of burning or scaling.
4. The cutting edge of a tool can be heated to any desired depth for hardening.







HEAVY-DUTY TYPES OF INDUSTRIAL FURNACE

Chromel-metal heating elements are placed in grooved refractories or muffle plates and are held in position by T-shaped supports fitting into recesses in the sides and roof, which are made of fire brick.

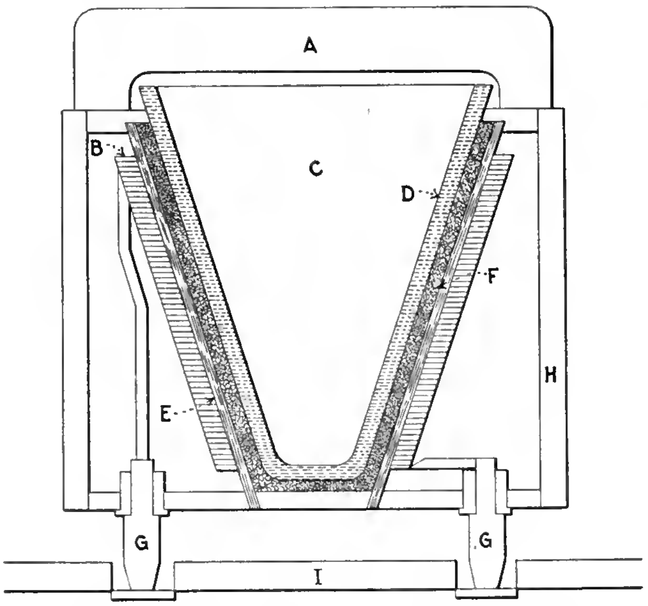
5. Labor cost in tool hardening is reduced and production increased.

As has been mentioned, the chromel resistor is not good for maximum working temperatures above approximately 2 100 deg. F. In searching for a resistor material which could be used in furnaces for applications requiring temperatures above 2,000 deg. F., and after a number of unsuccessful attempts had been made to use carborundum or silicon carbide for such work, a furnace was devised which shows considerable promise for the future. In this furnace the resistor element consists of a pile of carbon plates held together by spring pressure. An experimental furnace of this type has been kept at a forging temperature of 2,300 deg. F. for six weeks at a time and used in an extended operation, heading bolts. This furnace is 4 ft. long, 3 ft. deep and 4 ft. high over all and is mounted on 2½-ft. legs. The chamber is 30 in. long, 9 in. deep and 20 in. high. It takes from 16 kw. to 40 kw., 1,000 amp. to 1,200 amp., over a 20-volt to 60-volt range. In the operation of heading bolts the input was from 16 kw. to 22 kw. for small and medium-sized bars. The carbon resistor plates are 6 in. x 2½ in. x ¼ in. thick, and the pile of plates is held together by 200-lb. spring pressure. The heating element has been found to handle 100 kw. safely. Water-cooled bronze terminals are provided. The roof above the element consists of 4-in. x 4-in. carbon bars covered by from 6 in. to 8 in. of carbon dust and two layers of insulating brick. "Carbofrax" and firebrick are used in the side wall. It was found that the element must be protected by oil or gas flame from oxidization in order to have reasonable length of life. One gallon of oil or 100 cu.ft. of gas per day was sufficient. It was also found that the life of the element could be extended materially by changing the construction so as to seclude the element from the furnace chamber in a trough covered by "Carbofrax" brick or by a carbon plate protected by a covering of coke dust or granular carbon, and the earlier experimental construction is no longer used.

While the future for this type of furnace in forging work looks promising, the same principles have been employed in an experimental way in a muffle-type calcining furnace and also in a brass furnace, and the interesting results have been in the brass furnace, with an input of 50 kw., 100 lb. of metal in cold pigs has been melted in fifteen minutes.

A review of what has been done and the possibilities for the future in high-temperature work could be incomplete without reference to high-frequency inductive

heating, by which method temperatures above 2,550 deg. F. are readily obtained without carbon being essentially associated with the operation of the furnace. This type of furnace seems to have a multitude of applications. One of these is the melting of metal and alloys where low volatilization losses are essential, as in the case of molybdenum, platinum, gold and silver alloys. The furnace may also be used in graphitization work, when the carbon blocks to be graphitized are embedded in lampblack or carbon black, or in the heat treatment of knife blades and thin steel sheets. One of the miscellaneous applications which have been suggested is the manufacture of centrifugal castings.



HIGH-FREQUENCY INDUCTIVELY HEATED CRUCIBLE FOR MELTING PLATINUM, GOLD AND SILVER ALLOYS

A—Lid; prevents radiation and conduction of heat to the outside, confining heat to the crucible interior.
B—Electrical coil; carries the current, which produces the heat inside the crucible; coil itself is water cooled, making the furnace box cool and comfortable to work with.
C—Metal; where the heat is generated and left.
D—Crucible lining; holds the metal and helps keep the heat in the crucible.
E—Electrical insulation; for protection and to help keep the heat in the crucible.
F—Heat insulation; keeps the heat in the crucible where it is generated.
G—Terminals; where circuit is broken by lifting crucible to pour.
H—Box; for mechanical rigidity and ease of handling.
I—Table; supports the electric crucible and provides contact to the electrical power supply.

In order to provide the high-frequency power required for this type of heating, a frequency converter is employed for sizes up to 20 kw. per phase. This converter consists of an oil-cooled transformer with internal reactance, a set of static condensers and a metal discharge gap. For larger capacities it seems probable that a high-frequency alternating-current generator will be required. Such generators have been built and are obtainable. The electrical manufacturers appear to have no hesitancy about building this type of generator in larger sizes of, say, 200 kw. or 400 kw., at a frequency of 10,000/12,000 cycles, and it is probable that such capacities will take care of all the applications of this type of furnace.

The future will see a greater application of electric heat. Glass annealing will undoubtedly be done to a much greater extent by electricity. A total possible connected load of 60,000 kw. has been estimated. It is considered that the temperature gradients in the mass of homogeneous glass are solely responsible for the setting up of strains. Very accurate temperature control, such as is obtainable by electrical means, is therefore desirable. This should be within plus or minus 4½ deg. F., and the temperature required usually lies between 1 000 deg. and 1,450 deg. F.

An interesting account of the boiling of linseed oil with electric heat appeared in *Chemical and Metallurgical Engineering* for Nov. 2, 1921, page 844, and an account of the use of electric heat in the Western mining industry for the drying of fine concentrates, printed in the *Engineering and Mining Journal* of May 28, 1921, gave cost figures of from $5.66 to $6.86 per ton of water extracted with power at 0.65 cent per kilowatt-hour. Many other processes will be electrified, owing to the superior quality of product, even with high-priced power. Others will be electrified where power is cheap or where waste hydro-electric power is available.

In the textile industry in some localities the slashers, the tentering machines and the singeing machines will probably be electrified, as well as the dye vats and various other apparatus. In considering the extension of electric heating into this industry, the following advantages have been indicated: (1) More uniform heating of liquids, dyes and size; (2) more uniform consistency of liquids in dye vats, etc.; (3) elimination of steam piping and its losses; (4) higher temperature, taking the place of additional dry cans in increasing production; (5) higher temperatures in calender rolls and more uniform temperature throughout rolls than is obtainable with steam or gas heat.

In the paper industry, particularly where power is cheap or waste hydro-electric power available, there should be further use of electrical heat. This will probably be in the cylinders of the board machine, in the calenders and in the general steam requirements.

Even the time-honored limekiln is likely to be invaded by the metallic-resistor heating element some time when waste or cheap hydro-electric power is available. In the modern coal-fired limekiln 500 lb. to 1,000 lb. of coal is burned per ton of lime produced at a temperature between 1,100 deg. and 1,650 deg. F. Industrial engineers have recently projected an electric limekiln employing metallic-resistor heating elements in a locality where fuel for the fuel-fired kiln is difficult to obtain and some excess hydro-electric power is available, and they expect to obtain a ton of lime at an expenditure of about 3,400 kw.-hr.

## Germans Seek to Hasten Electrification

UNQUALIFIED public and professional interest is centered on the German government's present efforts to circumvent the coal shortage by the electrification of all state railways, says United States Consul B. S. Hayen, Leipzig, in a report to the Department of Commerce. By demonstrating the superiority in service and economic efficiency of electricity over steam it is hoped to offset the handicap to German railway transportation resulting from the occupation of the Ruhr coal fields and the deliveries previously made under the Versailles Treaty. Not only railways, but factories, will be compelled to use electric power. Lack of coal has forced the German State Railway Administration to withdraw a large number of trains. Even now the remaining trains run principally on imported English bituminous coal. Leipzig is already the terminus of several electrified lines.

# Man Development in Public Utility Companies*

## The Personnel Problem that Confronts Every Central-Station Manager—His Responsibility to Either Release or Build Up His Men

BY H. A. LEMMON
Personnel Department, Stone & Webster, Inc., Boston, Mass.

PROBABLY all central stations have men in their employ who are not equipped temperamentally or otherwise to gain success in this very exacting business, and yet who are gifted in many respects and still young enough to prosper in other lines. Perhaps many of these were employed at a time when of sheer necessity standards were somewhat relaxed. Presumably they have rendered the best service that they are capable of giving, and if so are clearly entitled to sympathetic consideration.

> THERE is no single problem of utility operation today more deserving of executive attention and guidance than that of the development of personnel. Whether the central-station staff number, twenty-five employees or five thousand, the importance of those individuals to that organization is equally vital. For here is a public service corporation, owned by the people through share holding, regulated by a popularly appointed commission, and dependent for its prosperity upon public sympathy and approval. Its employees are in constant contact with the people of the community it serves, and only by their representation is the company known. The kind of men and women who work for and speak for the light and power company make the character of the company in the mind of all its present and prospective customers. The question is how can the right kind of personnel be developed? It is this point which Mr. Lemmon discusses in this article.

Utility managers should frankly discuss the situation with all such, picture to them the probability of a greater measure of success in other lines, advise with them, and help them to become established in new activities. One may expect that within a reasonable time the industry as a whole will become more active. Men will then be in greater demand than now, and every effort should be made to assist "misfits" in obtaining employment with some other concern conducting a business more congenial to them. Even with present conditions, it is not clear that the industry is making as earnest an effort to accomplish this very desirable improvement as it can and should.

Any one can eliminate many applicants for positions as being ill trained or temperamentally unfit, but no man can and no system has yet been devised which will eliminate all of them. However, certainly two years' observation at most of a young man actually on the job and associating with his fellow employees and coming in contact with people outside should be a sufficient time in which to enable one to determine his fitness for public service. If there is any substantial doubt in the minds of his superiors, he should be carefully tested and considered, and if still found measuring up as anything less than desirable, he should be weeded out. Fairness to the man himself, if there were no other consideration, dictates this course. Yet we have not always so done, and the fact that we have not is responsible for the further fact that unfortunately there is much dead wood in many departments of most companies.

If we do not part company with the undesirable employee in the early stages of his employment, we are certain to wish to do so later, when perhaps so many years have elapsed that we are responsible for a conviction on his part that his position is permanent, and that, too, when he has passed the period of mental flexibility which would have enabled him to begin all over. We assume a tremendous responsibility by retaining in our service any newly made employee unless we are reasonably certain of his adaptability. It is no hardship to discharge a *young* man from the employ of an industry to which he does not belong, but it is nothing less than a tragedy to turn loose upon the world an old man whose long years of employment with us have robbed him of ability to adapt himself to other conditions. Our industry will avoid this crime against the man if it will be more ruthless at the beginning.

Promotion from time to time and increase in salary, however small, are official notice to the employee that he is making good. Except in rare circumstances, no such notice should be given unless it is a really significant one and will be interpreted by the employee.

In times gone by some utility managers have been guilty of recommending men for promotion for the sole purpose of getting rid of them. There is the typical case of a man who was recommended for, and received, five transfers to other companies and only after seventeen years' service was there found a manager with courage enough to proclaim him unsuited to the business, and yet in going back and interviewing fellow employees and superiors who had been with him at various parts of his career it was learned that he never had been desirable in any of his previous positions.

His first manager admitted this to be true and yet recommended him for transfer and promotion. It would have been easy to have corrected the mistake of his employment when his deficiencies were first discovered, inasmuch as he is a man of intelligence and industry and doubtless would have enjoyed a reasonable measure of success in some other line of business. Moreover, he was an unmarried man at the time when his faults should have been first discovered and was without serious financial responsibilities. Now he is the sole support of a mother, a stricken father, and has an invalid wife and two children, one of whom is feeble-minded. Lack of courage to face an unpleasant duty, or lack of interest, has robbed that man and his family of seventeen years of his life—more than that, it has robbed him of his chance for a future of reasonable contentment and progress.

We talk much of accident prevention. We might well interpret this to mean the exercise of our best efforts to prevent accident to the material welfare of our employees—a paralyzing disaster to the daily lives of the "misfits."

There appears to have grown up in the minds of some company officials a feeling that the young man sent to them from the headquarters office comes stamred with the parent organization's seal of approval. Such is not the case. Six to eight months in the home office, under supervisions, may or may not tell the story. Many a young man develops traits and characteristics in the field of which he gave no visible evidence while

*From a paper read recently before the Stone & Webster managers.

in the head office. These young men are on trial, and with precisely the same standing as the young men a local manager employs. Give them no favors. Judge them on their merits, and if found wanting, notify the department head from which they were sent.

No proper manager will recommend for promotion any man whom he would not like to keep in his own organization. Consciences in the past have sometimes been anesthetized by the thought that perhaps the man, though a failure with his present manager, would be successful if he might be transferred to a different environment. This actually occurs just frequently enough to prove that the theory is not without foundation in fact, but it is the exception rather than the rule, and in any event we can much better justify losing a few good men than we can justify becoming committed for the future of many indifferent ones.

Men are developed by having increased responsibilities placed upon them—ordinarily through promotion in the company with which they are connected or by transfer to a similar position in a larger company. Transfers are expensive to all parties concerned, but many years' experience of the Stone & Webster organization has demonstrated their efficiency and their desirability. They are rendered extremely difficult, however, in many instances by managers demanding a finished product to fill their open positions, instead of being content with a man who has had some experience but who, above all, can quickly grow into his new work. Unless the new job is actually a bit bigger than the man who is transferred to it, nothing whatever has been gained by the change except the filling of a position, while on the other hand an opportunity for man-development has been lost, perhaps for years. Every company must be a training school in continuous operation.

If we might take any given company and start fresh, selecting its new personnel from any and all available sources, the problem of building up that particular organization would be extremely simple. However, there is no such happy and easy solution. What we actually have to do in practice is to take such units as we now possess—inefficient and otherwise—working each over into the things he can do best and thereby shape all into a smooth-working machine. Some of our own companies present remarkable illustration of the possibilities of creating an unusually strong organization without any stars in the cast.

### Supervising and Graduating Men

Supervision is the magic formula for producing results in either man or property development, but as applied to men it doesn't mean sleuthing and, above all, it doesn't mean nagging. The failures of employees' associations, clubs and benefit societies, staff conferences, company spirit and cohesion and so on are almost invariably due to lack of the right sort of supervision. One cause of man failure in industry as a whole—and perhaps to a considerable extent in our own—is a natural tendency to set aside a considerable group of employees as occupying merely minor positions. In the public utility business—both from a standpoint of public relations and man development—there is no such thing as a minor position.

It has been said that if we very materially raise the standard of our personnel we cannot hold many of the best of our recruits—that they will not be able to advance as rapidly with us as their talents merit, and that therefore we shall find ourselves in the position of training men for other institutions. Even so, we can view many things with less equanimity than a situation in which our personnel shall be largely made up of brilliant young men who, having been trained in both the Stone & Webster spirit and ideals, will often enter into commanding positions with other great leaders in industry and still retain their affection and their regard for our organization. Promoting men out of our organization into better positions with others—under proper conditions—is not to be contemplated with alarm but with pleasurable anticipation.

### Relative Fields of Space Radio and Carrier Current

*To the Editors of the* ELECTRICAL WORLD:

I was very much interested indeed in the article by R. C. Denny of the San Joaquin Light & Power Corporation regarding its experience with radio telephones. The article is an excellent one and is timely.

In my opinion, a sufficiently strong case could have been made for the radiophone without putting arbitrary limitations on the carrier-current system. The carrier-current system will not, of course, meet all needs. However, we do not know its limitations even in the present first stage of development, and we should not therefore set up any limitations on its use at this time except the one limitation that there must be only conductors running between the two points between which we desire to communicate.

The article brings out the long distance over which broadcasting has been heard and the number of these long-distance receptions. It would be very interesting to know also how reliable the radio communication will be between the stations during the summer period when static is bad, and most particularly during lightning storms. Lightning is one of the major causes of transmission and station trouble in many districts, and a communication system which is put in with the idea of functioning at the time of electrical trouble when other means of communication have been interrupted should, of course, have very nearly 100 per cent reliability at these particular times.

The use of a loop receiving set with possibly some added features to improve selectivity works in the direction, of course, of reducing the effect of static. It is probably safe to say, however, that even the loop receiver will not permit completely reliable communication unless the received signal is exceptionally strong. It would seem that a 50-watt transmitter would not give a sufficiently strong signal over a distance of 135 miles to permit reliable communication during storms in that vicinity.

In this particular regard the carrier-current system appears to offer greater reliability than the radiophone system.

The radiophone will undoubtedly be used by a large number of companies operating over long distances, and the choice between a straight radio system and a carrier-current system can only be properly made after all elements that have a bearing on the case have been considered. We should not set up arbitrary limitations for either system and discard it on these assumptions.

The estimate of $1,000 per set, including transmitter

and receiver, is perhaps a little modest when all costs, including erection, are considered. However, the expense of $2,000 or $3,000 is small if it results in restoring service more quickly just a few times a year on a system of any magnitude.

The extension of the use of the carrier system can be made more rapid by continued reference to the installation of this means of communication as additional companies adopt it. This would be accomplished, of course, by each company submitting its experience in an article on the application of carrier current to its system when the system is installed.

### The World's Greatest Reservoirs

*To the Editors of the* ELECTRICAL WORLD:

My attention has been called to a letter by Wilhelm Fleischer, supervising engineer for the Norwegian Hydro-Electric Nitrogen Company, Norway, which appears in your issue of April 21, 1923, page 922. Mr. Fleischer states that his company has in Telemarken, Norway, the second largest reservoir in the world, the capacity being given as 768,000,000 cu.m.

Let me point out that the Quebec Streams Commission completed in the year 1917 what it asserts to be the largest storage reservoir for power purposes in the world. The Gouin Storage Dam, in the upper part of the St. Maurice River watershed, in the Province of Quebec, Canada, assures the control of the water which is supplied from a drainage area of 3,650 square miles (9,456 sq.km.). The reservoir created by this dam has a capacity of 160,000,000,000 cu.ft. (4,500,000,000 cu.m.), and its area is 300 square miles (780 sq.km.).

The Gouin reservoir is twice as large as the Assuan reservoir.

O. LEFEBVRE,
Chief Engineer.
Quebec Streams Commission,
Montreal, P. Q.

[The following tabulation of the approximate capacities of the largest reservoirs in the world is of interest in this connection. It is possible that some large European reservoirs are not included. The capacities are stated in millions of gallons. The figures for the American dams were compiled by the *Engineering News-Record*. That for the Assuan Dam is derived from an article in the *Engineering News* for Sept. 30, 1909, by F. H. Fowler, who puts the storage capacity of the reservoir before its enlargement at 795,000 acre-feet. According to the *Encyclopædia Britannica*, the raising of the dam, completed about twelve years ago, increased the former capacity two and a half times. This factor applied to Mr. Fowler's estimate figures out as indicated below, making the Assuan basin rank fourth in size. The *Encyclopædia Britannica's* own figure for the entire 200-mile reservoir created in the Nile was 3,750,000 millions of cubic feet with the old dam. Multiplied by two and one-half and converted to gallons this gives the enormous figure of 70,312,500 millions. Obviously, estimated in this way the Assuan reservoir is not comparable with any other.

| | Millions of Gallons | | Millions of Gallons |
|---|---|---|---|
| Gatun (Panama) | 1,373,000 | Moosehead Lake (Maine) | 177,000 |
| Gouin (St. Maurice River, Quebec) | 1,200,000 | Ripogenus (Maine) | 157,000 |
| Elephant Butte (New Mexico) | 863,000 | Clear Lake Klamath (Oregon) | 150,000 |
| Assuan (Nile River) | 650 000 | Shoshone (Idaho) | 149,000 |
| Roosevelt (Arizona) | 425,000 | Ashokan (New York) | 132,000 |
| Pathfinder (Wyoming) | | Twin Lakes (Maine) | 123,000 |
| | 349,000 | Hebegen (Montana) | 115 000 |
| Lake Winnibigoshish (Minnesota) | 338,000 | Tirso, not completed (Sardegna, Italy) | 110,000 |
| Jackson Lake (Idaho) | 276,000 | Medina (Texas) | 98,000 |
| Burrinjuck (Australia) | 252,000 | Big Meadows (California) | 96,000 |
| Leech Lake (Minnesota) | 247,000 | Bridgewater (North Carolina) | 94,000 |
| Mosvand, Telemarken | | Lahontan (Nevada) | 94,000 |
| (Norway) | 203,000 | Arrowrock (Idaho) | 91,000 |

Of these dams the last-named, at Arrowrock, Idaho, is the highest. It measures 354 ft. to the top of the parapet wall.—EDITORS.]

### Underground Transmission at 150,000 Volts

*To the Editors of the* ELECTRICAL WORLD:

The Pacific Coast practice of joining distant power stations by a network of tie lines and operating them as a unit has gradually spread eastward until it has invaded the populous regions where electrical transmission must be of necessity by underground cables. The interest now being shown in "superpower systems" indicates that the near future will see an important demand for insulated cables of increasingly higher voltages.

The city of Paris has a 60,000-volt system using single-conductor cables, and a large system in the Middle West is now contemplating 132,000-volt underground transmission. The day when 150,000-volt underground systems will be required is not far distant.

A well-known professor of electrical engineering told his students that the problems he gave them differ from those they would encounter in practice in that the former were always capable of solution whereas the latter seldom were. Then, with a twinkle in his eye, he added that insoluble problems could generally be solved by eliminating certain unessential conditions which had been unconsciously assumed and thereby converting them into soluble problems. The insoluble problem of cable engineering is to make insulation of a fixed thickness and slowly improving quality carry greater and greater transmission voltages. The unessential condition in this case is the assumption that the transmission voltage cannot be raised without putting a greater stress on the insulation. Years ago, however, the invention of the three-phase system with grounded neutral enabled the transmission voltage to be raised 73 per cent without increasing the stresses in the insulation, proving this assumption to be unnecessary.

A. M. Taylor* has carried this idea further, first by conceiving of a six-phase instead of a three-phase system which would increase the ratio from 1.73 to 2.0. He then amplifies this scheme by resolving each phase of a three-phase star into six components 60 deg. apart by bringing the other two phases into play through special transformers. He thus obtains an eighteen-phase system for which six three-conductor cables are required. The transmission voltage then becomes three and one-third times the voltage between adjacent phases, so that 45,000-volt insulation may be used for 150,000-volt transmission.

Mr. Taylor proposes to use concentric three-conductor cables, but all the advantages of the scheme would not be lost if ordinary triplex cables were used, as its essence is to place conductors between which the diametric voltages are imposed in different cables and thus split the insulation into separate elements. Mr. Taylor's paper is largely devoted to an extended and somewhat complicated account of this idea. The details of his calculations may be questioned by American engineers who are prepared to operate their cables at higher temperatures and stresses than he assumes, but the general idea is well worth consideration where the complication of transformers and switching apparatus which is involved is not too serious a factor.

The real interest in the scheme is the idea of raising the transmission voltage to such a high value compared with the voltage between conductors. Perhaps other and simpler ways of doing this may be devised.

WILLIAM A. DEL MAR,
Chief Engineer.

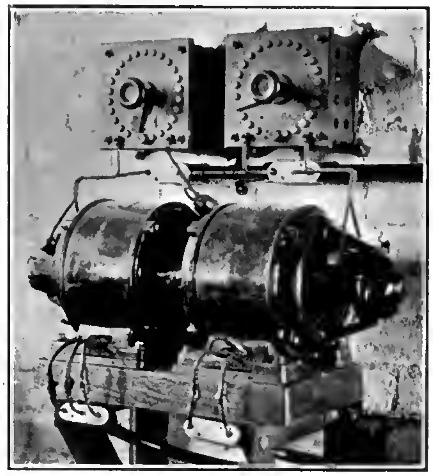
# Central Station and Industrial Practice

**Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants**

## Protection for Frequency-Changer Sets

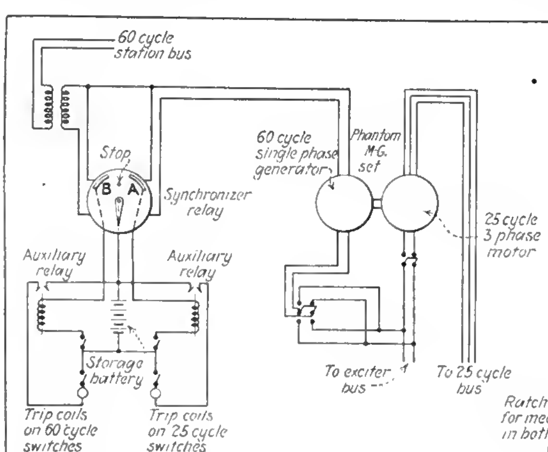
WHERE two systems of different frequencies are tied together through frequency changers it is difficult to provide relays which will protect the machines against overload and at the same time permit an interchange of power between the systems. The Central Arizona Light & Power Company has recently perfected a novel device for overcoming these difficulties. It consists of a small phantom synchronous motor-generator set and a contact-making synchroscope, shown in the accompanying illustrations.



PHANTOM MOTOR-GENERATOR SET WITH CONTACT-MAKING SYNCHROSCOPE PROTECTS FREQUENCY CHANGERS

The city of Phoenix, Ariz., is supplied with power from two sources, one source comprising a group of five hydro-electric plants, part of the reclamation system of that vicinity, which deliver energy over an 80-mile line. This system, with an aggregate rating of about 19,000 kw., operates at 25 cycles. The Phoenix company converts this 25-cycle power to 60 cycles for local distribution by synchronous motor-generator sets and rotary converters with a total rating of about 4,500 kw. Power is also obtained at 60 cycles from the hydro-electric and steam plants of the Arizona Power Company over an 85-mile line. This system has a total capacity of 12,000 kw. and is tied into the Phoenix buses. The motor-generator capacity at the Phoenix plant is in several units, so that at times less than 1,000 kw. is in service to hold in synchronism a 25-cycle system of 19,000 kw. and a 60-cycle system of 12,000 kw. Exchange of power is sometimes desired from one of these systems to the other through the motor-generator sets. When either system experiences severe transmission disturbances or develops a sufficient fluctuation of speed by reason of overload, the motor-generator sets, being of insufficient capacity to hold the other system in synchronism, are thrown out of step, subjecting the station apparatus to severe strains. These strains were such that the slot wedges of the generator stators have been pulled out and the cement grouting under the bedplates driven out for a distance of several feet. Reverse-current relays in both of the incoming line could not be employed to protect the frequency changers from these strains because of the desire at times to exchange power between the two systems. After ineffectual efforts to obtain a relay which would permit the flexible operation desired and at the same time protect the motor-generators, the apparatus described here was devised by H. L. Aller, vice-president of the company. A small synchronous motor-generator set was built, the 25-cycle motor of which is operated from the 25-cycle buses. The 60-cycle generator has but one phase winding, correctly placed to correspond with the windings of the large frequency changers. This winding is connected to one winding of an old synchroscope, the coils of which would permit of continuous excitation. The other winding of the synchroscope is connected to the corresponding phase of the 60-cycle station bus. The phantom generator is not paralleled with the 60-cycle system, and, being without load, the synchroscope shows at all times the difference in phase

FREQUENCY-CHANGER PANELBOARD



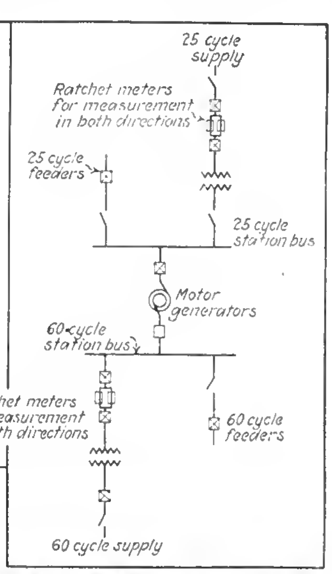


FIG. 1 (ABOVE)—SCHEMATIC DIAGRAM OF PHANTOM MOTOR-GENERATOR AND SYNCHROSCOPE RELAY CONNECTIONS. FIG. 2 (AT RIGHT)—DIAGRAM OF 25-CYCLE AND 60-CYCLE STATION CONNECTIONS

relation between the two generating systems. When either system begins to lag in speed, the synchroscope needle is deflected from its zero or normal position, the direction of deflection being dependent upon the relative speeds or frequency of the two systems. The exact position of the synchroscope needle when the frequency changers are pulled out of step was ascertained by trial, and contact-making plates were placed in the synchroscope face at these positions. When the needle touches plate *A* (Fig. 1) a positive acting relay, through the station storage battery, opens all of the switches connecting the Phoenix station to the 25-cycle system, leaving the Phoenix load connected to the 60-cycle system. The reverse action of the synchroscope makes contact with plate *B* and in like manner isolates the 60-cycle system, leaving Phoenix feeding from the 25-cycle system. An exchange of power can be effected from either system to the other up to the point when the motor-generators would pull out of step, at which point the system being fed is thrown off and entirely disconnected.

W. C. HORNBERGER,
Assistant General Manager.
Central Arizona Light & Power Company,
Phoenix, Ariz.

# Extracts from Operating Code

BY FIELD EDITOR ELECTRICAL WORLD
New York, N. Y.

## Operating Centrifugal Pumps for Boiler Feed

THE discharge and suction valves of boiler-feed pumps of the centrifugal type may be kept open because a check valve is placed on the outlet of all such pumps. The equalizing connection is placed on the pump to help balance the thrust along the shaft and thus relieve the thrust bearing of some of its work. The pressure regulator is not placed in service until the pump is delivering proper pressure to prevent erratic action while the pump is coming up to speed. When the regulator is cut in, the steam line is opened before the water line, to prevent an unbalanced water pressure in the regulator from closing off the steam in the turbine. Usually a cold-water spray line is tapped into the pump suction, the function of which is to admit cold water to the pump when it becomes vapor-bound from pumping hot water. The valve of this spray line should be kept closed except when it is needed, because, when open, the water going to the boiler is undesirable, lowered in temperature and is also not metered. The following instructions for starting and shutting down boiler-feed pumps of the centrifugal type are part of the operating code of the Philadelphia Electric Company, from which they have been abstracted:

STARTING

1. See that the pressure gage on the discharge side of the pump is operating.
2. See that the suction valve is open.
3. See that the discharge valve is open.
4. See that the pressure regulator valves are closed.
5. See that cooling water is on the bearings and seals.
6. Start the turbine or the motor and bring up to working pressure.
7. See that the proper pressure is on the equalizing pipes to balance the thrust.
8. Inspect the oil system.
9. Open the steam-line valve to the pressure regulator.
10. Open the water-line valve to the pressure regulator.
11. Adjust the regulator to give the proper differential between the feed pressure and the steam pressure. In case of running pumps in parallel, the load may be equalized by partially closing the suction and discharge valves on the pumps which are taking the most load.
12. Open the spray-line valve if the pump becomes steam bound.

SHUTTING DOWN

1. Close the spray-line valve, if open.
2. Shut down the turbine or motor.
3. Close the steam-line and water-line valves to the pressure regulator.
4. Shut off the cooling water from the bearings and seals.
5. Close the suction and discharge valves, if the pump is to be dismantled.

## Method of Paralleling Phase-Balancer Exciters

WHEN operating two or more phase converters with voltage balancers in parallel, it is also desirable to parallel their exciters and auxiliary exciters, so that the load will be equally divided among the converters. The following instructions have been abstracted from the operating code of the Philadelphia Electric Company and apply in particular to the phase-converter installation at the Schuylkill No. 2 station. Instructions for starting and shutting down phase converters were given in the last issue of the ELECTRICAL WORLD, under "Extracts from an Operating Code, page 1042.

Paralleling phase-balancer exciters and their auxiliary exciters:

1. Close the field switches for No. 1 and No. 2 auxiliary exciters in the "down" position. This is an interlock on the "close" control circuit for the equalizer breakers and the balance-exciter tie breaker.
2. Push the button-type control switch "in" and hold until both red indicating lamps show that the equalizer breakers and the balance-exciter tie breaker have closed.
3. See that all limiting resistance switches are open.
4. Close the two field switches for the auxiliary exciters (mentioned in No. 1) in the "up" position simultaneously. The phase-balancer exciters and their auxiliary exciters are now in parallel.

To "cut apart" phase-balancer exciters and their auxiliary exciters:

1. Pull the button-type control switch "out." The equalizer breakers will open simultaneously as indicated by both green lamps.
2. Either or both of the field switches for the auxiliary exciters may now be closed in the "down" position.

To feed No. 1 phase-balancer field from No. 2 balancer-exciter, or vice versa:

1. Close No. 2 balancer-exciter circuit breaker if starting No. 1 phase balancer, or vice versa.
2. Push the button-type control switch "in." The red lamp should indicate that the balancer-exciter tie breaker is closed.
3. Proceed according to Rules 12 to 17 inclusive of "Phase Converters with Voltage Balancers" (ELECTRICAL WORLD, May 5, page 1042). No. 2 balancer-exciter is now feeding No. 1 phase-balancer field, or vice versa. The interlock is so arranged that only one phase-balancer set can be fed with this connection.

Resuming normal operation, or shutting down with this connection:

1. Close the auxiliary exciter-field switch in the "down" position.
2. Proceed to shut down the phase balancer or to return to the normal method of operating.
3. Pull the button-type control switch "out." The green lamp should indicate that the balancer-exciter tie breaker is open.

## What Should Be the Proper Distribution Voltage?

FOUR-WIRE distribution at 4,000 volts is generally favored, and companies that are not now distributing at this voltage are rapidly adopting it, according to the opinions expressed at the recent meetings of the sub-committees of the Technical Section of the Pacific Coast Electrical Association. Greater capacity of existing circuits, better voltage regulation and the fact that 2,300-volt transformers on the lines can be

utilized by connecting between phase wires and neutral are the factors influencing this preference. Some engineers favor one three-phase regulator for four-wire, three-phase, 4,000-volt circuits, while others feel that satisfactory regulation can be obtained with one regulator.

The city of Los Angeles feels that 4,000 volts is not the answer to the city distribution problem and has adopted a 4,800-volt, three-phase, delta-connected system for its distribution, and transformers, regulators and other equipment are being purchased for this voltage. All transformers being purchased are insulated for 7,500 volts to ground so that the system may later be changed over to four-wire star operation if load conditions warrant.

San Francisco, Cal.

## Increased Coal Output by Better Mine Lighting

AS A RESULT of using six times the ordinary strength of illumination (the miners' standard electric lamp) the increase in coal output reached nearly 15 per cent, according to an investigation carried out in a Lancashire (England) coal mine on behalf of the Institute of Industrial Psychology. The more intense light was carried by men who had volunteered for the work. One of these carried the heavier lamp to the coal face during eight weeks with the following results: Average output per man per shift before use of big lamp, 2.47 tons; average output with new lamp, 2.83 tons, or an increase of 0.36 ton. The percentage improvement is 14.57 per cent. These figures refer to two men working together.

Deductions for dirt during the eight weeks' use of the big lamp decreased by 3.5 tons, equivalent to a reduction of 21.87 per cent. The man was now instructed to return to his ordinary lamp, and the following figures were obtained after a further eight weeks: Average output per man per shift during use of big lamp, 2.83 tons; average output per man per shift after use of big lamp, 2.57 tons, or a decrease of 0.26 ton, or 9.2 per cent. Deductions for dirt during this period increased by 5.95 tons, equivalent to an increase of 47.6 per cent.

As the workers in close proximity to these two men had no marked change of output, it seems reasonable to suppose that the cause of the increase was better illumination. It is suggested in the report of the investigation that the weight of the standard lamp might be doubled without proving a serious handicap to the miner. Such bright light would allow a margin of intensity which would permit diffusion of the light by means of a slightly opaque cylinder and thus add to the miners' comfort and powers of vision.

New York, N. Y.

## Radio Used to Locate Line Trouble

RADIO communication is destined to play a vitally important part in maintenance of continuity of service on high-tension power transmission lines in the future, in the opinion of operating officials of the Northern States Power Company. This newest form of communication already has been used successfully by the company in quickly locating "trouble" on its lines, and it has proved greatly superior to the wire telephone method previously used.

When the two St. Croix transmission lines tripped out at 1:55 p.m. on Jan. 30 both telephone lines to St. Croix were put out of commission. F. J. Gerlich, superintendent of the service department, lost no time in getting to the radio set and upon tuning in immediately heard the wireless operator at St. Croix calling Minneapolis. By means of radio-telephone communication the trouble on the transmission lines was quickly cleared up, and both lines were back in service by 2:05 p.m. (within ten minutes). Wire telephone communication was not reestablished until half an hour later.

### SEVERAL NEW STATIONS TO BE CONSTRUCTED SOON

Radio communication has been established between the St. Croix Falls hydro-electric plant and the Minneapolis office for several months, and a complete transmitting set now is ready for installation at the Coon Rapids hydro-electric station, 17 miles from the Minneapolis headquarters building. Plans are under way for installation of a high-powered station at Mankato, after which stations probably will be installed at Eau Claire, Wis.; Montevideo and Faribault, Minn., and eventually at Sioux Falls, S. D. It is expected to have the station at Eau Claire, and possibly the one at Montevideo, operating before the end of 1923.

The stations at Minneapolis and St. Croix are rated at 100 watts and use five 50-watt tubes—two tubes serving as oscillators, two as modulators and one as a speech amplifier. The circuit which is employed is known as a Colpit-Heising circuit, and the tubes are so arranged that one, two, three or five may be used, depending upon the power required for communication with the desired station. Motor-generator sets, rated at 750 watts and delivering 1,000 volts direct current, are used to deliver the required power to the sets.

These two stations are equipped for both telephone and telegraph communication, although they are designed primarily for the use of the telephone. Both sets are licensed for operation on a wave length of 525 m. and are in charge of licensed commercial operators.

The receiving sets are standard Westinghouse type RC single-circuit receivers. The Minneapolis station is equipped with a loud speaker and power amplifier, making it unnecessary for the operator to wear head telephones while operating the set.

## Is Megger Insulation Test Too Exacting?

AFTER an experience with the use of a megger for testing the insulation of a direct-current exciter and its wiring, which was put out of commission by a flood, it is the writer's opinion that the test is too exacting.

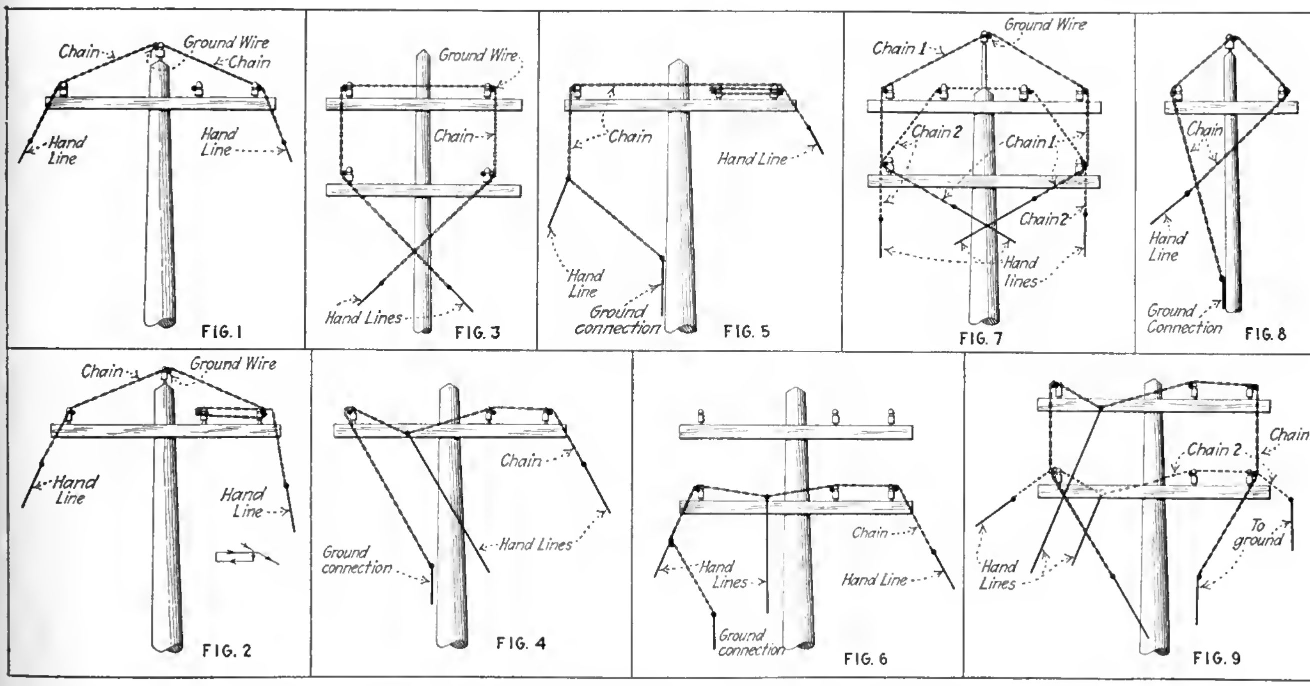
After the above accident occurred the exciters tested grounded both with megger and magneto. The armatures were removed and were prepared for a drying-out process with electric heaters, the field windings being subjected to the hot blast from the transformer core drier. The wiring from exciters to switchboard was installed in conduit and was also grounded. After seventy-two hours' drying the exciter armatures tested clear of grounds, but the field coils still showed a ground, although not a serious one. As the accident at this station crippled us considerably, it was decided to put the machines back in operation for a test run without removing the grounds. After a six-hour run the machines were put in operation under full load. After a twelve-hour run a megger test still showed a ground on the ex-

citer, although a test made two weeks thereafter failed to show a ground anywhere in the system. Had we waited until the megger tested clear we believe we should have been delayed for several days more. As you know, a central station man will take a chance to restore service that would be condemned by a factory service man.

S. G. HUNTER,
Operating Manager.
Malone Light & Power Company,
Malone, N. Y.

## Grounding Chain Practice Standardized

WITH the purpose of insuring uniform practice in the use of grounding chains by linemen, the Public Service Company of Northern Illinois has issued a set of rules accompanied by a diagram. These orders are the result of considerable experimental work by the testing department of the company to determine the most suitable method of grounding lines.



COMPLETE PROTECTION AGAINST ACCIDENTAL ENERGIZING OF LINES AFFORDED BY GROUNDING CHAINS

Various types of line construction used by the Public Service Company of Northern Illinois and the method of using chain to ground each one. All grounding methods shown are started from the left side of the pole excepting chain No. 1 in Fig. 7.

The instructions describe in detail and by blueprint just how chains are to be applied to the line under various types of construction with and without the overhead ground wire. If properly applied, full and complete protection against accidental energizing of lines from any cause while work is being performed on them is provided in the grounding chains. The instructions to linemen read as follows:

Whenever it is desired to take any transmission line out of service in order to repair or do any work on it, the recognized routine should be complied with. Furthermore:

If the line is reported dead by recognized authority, the party about to do the work will proceed to ground the line. Rubber gloves should always be worn when handling hand lines and chains while the latter are being placed on the transmission line. When the grounding is made by means of chains, the chains must be kept taut or no protection is afforded by them, and the following rules must be observed:

1 *Class A and B single-circuit construction with ground wire, with or without distribution lines on same poles.*

A single length of chain 25 ft. long with a hand line of suitable length, strength and insulation attached to each end appears to be the most suitable for grounding and shorting on these types of line construction. This is to be applied as follows:

One hand line will be thrown over all the wires, including the ground wire, and the chain pulled over these wires to make contact as shown in Fig. 1, a good strain being maintained on the chain and hand lines throughout this procedure. The first-mentioned hand line should then be thrown over the remaining wire and the chain pulled taut as shown in Fig. 2, or pulled into contact with the remaining wire while taut, as shown in Fig. 3. Precaution should be taken to keep the chain away from any distribution lines at any stage of the work. Care must also be taken not to come in contact with the chain or the line conductors until all the conductors and ground are in good contact with each other through the chain.

2. *Lines without ground wire.*

A chain of such length to reach across all conductors and extend to ground will be used. For this purpose a sufficient number of the 25-ft. lengths should be coupled together to furnish the necessary length. One end of this chain is to be clamped to an established ground and a hand line attached to the other end of the chain. The hand line will then be thrown over all the wires and the chain pulled into contact with at least the two outside conductors, as shown in Fig. 4. The hand line will then be thrown over the remaining wire by throwing the hand line up between the two line wires with the wide spacing and the chain pulled taut, as in Fig. 5.

3. *Other types of construction.*

Methods of grounding other types of construction in use in the Public Service Company territory are shown in Figs. 6, 7 and 8. Fig. 7 makes use of two separate grounding chains. If a distribution line is attached to the poles carrying a transmission line upon which it is intended to place a ground, it is necessary that the chain be kept clear of the distribution lines at all times.

When the line conductors are to be parted or are already separated, one chain should be placed on either side of the place where work is being done if there is the remotest possibility of either end of the line becoming energized from any source whatever. After the work is completed, chains must be removed from the line first, before being disconnected from ground, and line cleared and put under orders of the system operator.

FIG. 1—PRESENT FORM OF RECORDING INTERRUPTIONS ON ALABAMA SYSTEM, ON WHICH DATA FOR EACH TRANSMISSION LINE ARE CLASSIFIED BY DATE, CAUSE AND DURATION

## Analyzing Causes of Interruptions

TO MINIMIZE interruptions of service the Alabama Power Company requires that very accurate records be kept of interruptions, their cause and duration, so that efforts can be made to prevent their repetition. Now the records are kept in the form shown in Fig. 1. This form is considered preferable because it tells at a glance what outage any customer on any line has suffered, its cause, duration, etc. Once a year this information is recapitulated in the form shown in Fig. 2 so that the most serious causes of interruption can be attacked and removed.

As indicated by the form in Fig. 1. now in use, records are kept for each line. Interruptions of service on the whole line are classified by date, time, cause and duration. Opposite each space are places for showing interruptions to individual customers' service, their cause and duration as well as any remarks pertaining to any unusual conditions encountered.

### Poles, Guys and Crossarms Most Vulnerable Parts

As may be seen from Fig. 2, which recapitulates the serious interruptions of the year 1920, the most serious interruptions on the 110,000-volt lines from the viewpoint of duration were due to poles, guys and crossarms. These were extremely unusual cases of trouble, however, as the two interruptions thus ascribed were both caused by a cyclone on April 20, 1920, which destroyed two structures on the Huntsville line and five structures on the Sheffield line, causing lines to go out for a total of 3,720 minutes as noted. In terms of number of interruptions, lightning was the most serious cause. On the 110,000-volt, 44,000-volt and 13,200-volt buses the most serious cause of interruptions from the viewpoint of duration and number was trouble on other sections of the system, as distinguished from trouble on the buses themselves. The same was true on the distribution system. The degree of seriousness of other causes is indicated.

From this analysis and the correction of weakness which it permitted the interruptions have been greatly reduced, because it has been possible to direct attention where it was most needed instead of aimlessly attacking all possible causes.

## A Well-Planned Merchandise Salesroom

**A Study of Ideas that Have Been Carried Out in the Arrangement of the New Display Room of the Kansas Gas & Electric Company in Wichita**

THE Kansas Gas & Electric Company in its new general office and salesroom in Wichita has given a most interesting demonstration of the value of careful planning in a central-station display room. The company's officials believe that an attractive merchandise display not only sells more appliances but raises the standing of the business of the company in the eyes of the public and therefore contributes to the development of energy sales as well.

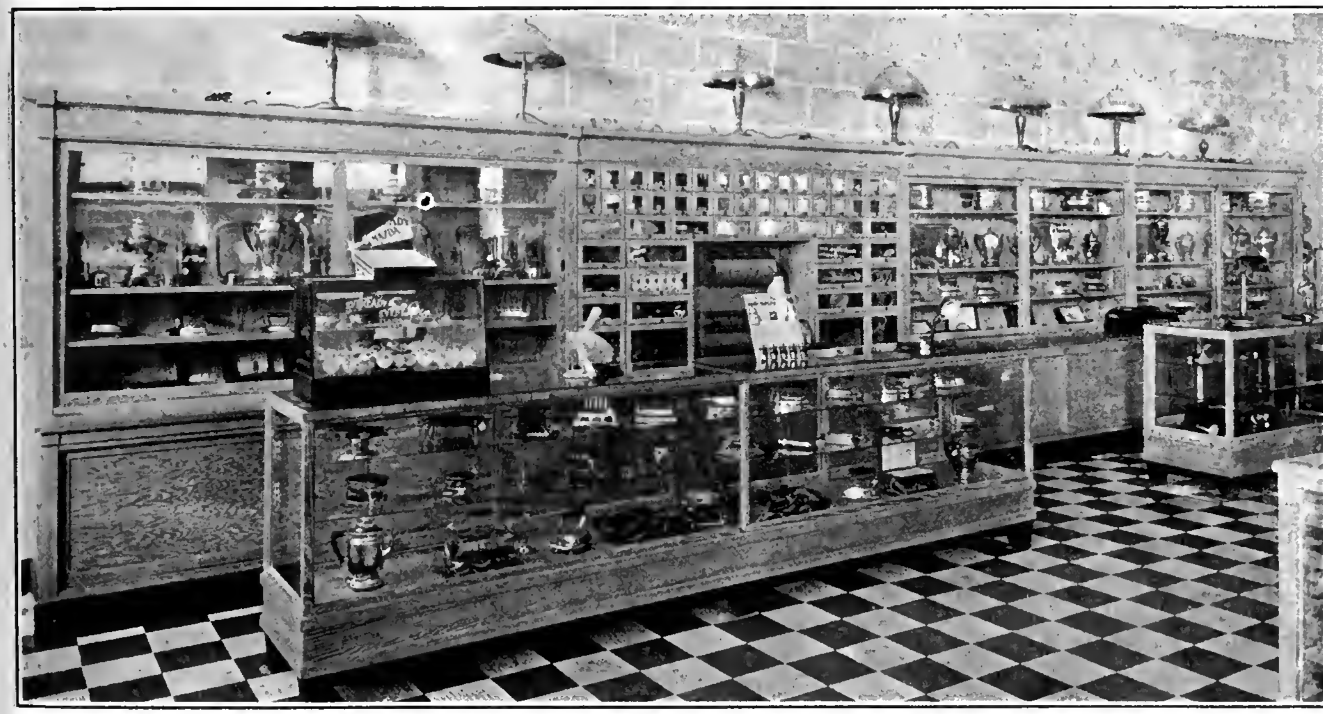
A consumer cannot pass through such a room to the cashier's window or the adjustment window without feeling the effect of the attractive display of merchandise and without gaining a higher respect for the company as a local business concern. Whether it is admitted or not, the feeling of pride in local enterprise is bound to be stirred. All this helps in maintaining public interest and good will for the company.

The primary object, of course, is the sale of merchandise. To accomplish this there is a definitely planned arrangement of the floor space and equipment so that the merchandise can be displayed to the best advantage as the seasons change.

The salesroom in this building, into which the Kansas company has just moved, is the headquarters from which it serves about thirty communities in central and southern Kansas and is an example of the most improved practice in central-station salesroom arrangement. Reference to the illustrations shows that, in place of the usual showcases in the center of the floor, almost the entire floor space has been left clear. The merchandise which is being pushed hardest, either for seasonal or other reasons, is placed in the most prominent positions. The customers' room, where all bills are paid, where troubles are adjusted and other business concerned with the sale of energy is transacted, is at the rear of the merchandise salesroom, and persons visiting the customers' room pass entirely through the display.

Particular thought has been given to the arrangement of the displays on the floor so that merchandise that requires especial educational or promotional support shall have a strong position and conspicuous display. On studying such merchandise it will be found that certain articles occupy a more staple place in the general demand than does the rest of the stock handled. Every effort is made to give this type of merchandise a prominent and permanent location on the floor so that the volume of sales can be maintained.

While the center of the floor in the Wichita display room has been



Here is a most ingenious innovation in the electric shop, adopted from hardware practice. Behind the glass counter-case is a display unit largely made up of drawers, each with a display compartment in the front where samples of the device carried inside are shown behind glass. Customers can easily select repair parts.

## Glimpses of the Kansas Gas & Electric Company's Wichita Salesroom

THE most interesting feature of this merchandise display room is the obvious fact that it is planned to promote sales: (1) The show windows are large and line two sides of the building. (2) A bright sign calls from afar. (3) The entrance is in the center on the corner. (4) A three-step, movable display platform presents the most seasonable appliance as the customers enter. (5) One aisle of the display floor, with the lamp counter in the rear, with lamps of all types and sizes connected for demonstration. (6) Another aisle and the main counter where small appliances are displayed and sold. (7) A view through the center of the salesroom, with the "customers' room," where bills are paid, in the rear.

left clear for the larger articles and the counters apparently occupy a secondary position in order to make the handling of merchandise displays more flexible, this lack of the usual large central counters has been compensated for by placing small counters for appliance display around four of the square columns that support the upper floors. This does not interfere with the use of the floor space for the heavier displays. The main counter has been placed at the extreme left side of the room, away from the main entrance, but convenient to any one coming in from the building hallway and passing on to elevator and building stairway.

Another idea in the arrangement of counters is the placing around one of the square building columns in the customers' room of a glass-top counter which serves the purpose of a writing desk and at the same time permits the display of one specimen of virtually every type of smaller appliance sold in the store, in direct view of the customer who may be writing a check or a memorandum.

Perhaps the most attractive element in the entire salesroom is the display equipment itself, which has been developed to an unusual degree. Back of the main counter, for instance, is a set of glass-inclosed shelves for small appliance display. On the same level is a section of drawers which contain the small devices and other repair parts that customers are apt to call for. The front of each drawer is glass, and a partition is set just back of the glass panel to form a narrow compartment into which one or two samples of the articles carried in the drawer can be placed, so that they can be seen through the glass panel. This enables the customer, who may not have the slightest idea as to the name of the repair parts he wants, to select them by sight. This display case is adapted from hardware-store practice. Underneath these display shelves and drawers is a row of large drawers for stock in storage,

GLASS DISPLAY COUNTERS SURROUND THE PILLARS NEAR THE CASHIER'S WINDOW AND ARE USED AS WRITING DESKS

and practically all this stock on hand is kept in the display room, where it it is readily accessible.

There is a lamp-sales counter at the rear of the salesroom directly back from the main entrance and in the aisle through which most of those on their way to the customers' room pass. As will be seen in the illustration, a number of lamps are mounted in a row at the front of an opening into the case well above the level line of vision. This opening is finished with black inside as a background, and on the counter directly in front of the customer are a number of flush switches corresponding in number and position with the lamps. A sample of each kind of lamp is connected with the sockets, and the customer is aided in making a quick selection by turning on the light.

Another feature which has been adopted from the hardware store is a stepped platform on which the medium-sized appliances are displayed. For example, electric or gas heaters occupy this space during cold weather, and electric fans will be placed on the same device when the hot weather comes on. The banked platform consists of three steps, rectangular in form, and is mounted on castors so that it can be moved.

Space has been provided for the demonstration of either electric or gas ranges in the rear of the room. It is proposed to use this not only in connection with demonstrations put on by the company but in connection with the work of the domestic science department of the public schools.

Naturally a considerable amount of small repair work is brought into the salesroom, and experience has shown that the plan of receiving this work in the office and then sending it out to a repair department some distance away is not satisfactory, because many of the repairs are the work of a few moments only and the customer would like to wait for their completion. A small room to the rear of the main display room has therefore been provided for small repair work brought into the office. In this way all small repair work is kept within reach of the display room.

The Kansas Gas & Electric Company operates branch salesrooms in a number of smaller communities, and,

BRANCH OFFICE SALESROOMS AT CHERRYVALE AND ARKANSAS CITY, SHOWING TYPICAL ARRANGEMENT USED IN SMALLER CITIES

SALESROOM AT MOLINE, A TOWN OF 1,000 POPULATION

of course, these stores do not offer the same chance for planning and arrangement that is offered in the spacious new quarters in Wichita. However, the same principles are carried out so far as possible and no possible effort is spared to make them attractive. The picture of the rooms at Moline (1,000 population), Cherryvale (5,000) and Arkansas City (11,500) show how these ideas are carried out. One thing that should be noted especially is the way in which the small staple items are arranged. The counter with the triangular-shaped top in the picture of the Cherryvale office is the clearest illustration. This contains a variety of small staple articles and is placed so that it is close to the point at which the customer pays his bills. With his change in hand his inclination is often to buy an inexpensive article, and the arrangement of these counters has been found very stimulating to sales.

## New York Edison Exhibits Electro-Medical Apparatus

FOLLOWING its policy of promoting and encouraging the use of electrical energy in every conceivable manner, the New York Edison Company during the week of April 23-28 held an exhibit of electro-medical apparatus in its Irving Place showroom, to which were invited all members of the medical and dental profession. The leading manufacturers of apparatus exhibited, their displays including everything from diagnostic lamps and sterilizers to the most elaborate X-ray equipment. The exhibit was held under the auspices of the Bureau of Electro-Therapeutics of the Edison Company, of which Miss Mabel Martin, a registered nurse, is manager.

## What Other Companies Are Doing

**Louisville, Ky.**—For some time the Kentucky Utilities Company has sold lighting fixtures under an agreement with the manufacturer by which fixtures were furnished on consignment. This business has been very successful, and a new contract provides, in addition to the consignment arrangement, for a fixture salesman to be furnished at the manufacturer's expense. In view of this additional co-operation, the Kentucky Utilities Company has placed its lighting fixture sales quota for this year at $50,000.

**Berlin, Wis.** — The Wisconsin Power, Light & Heat Company has made a definite step toward helping merchants to improve the appearance of the business district at night by reducing the rates for window and display lighting to about half the former rate. The proposal of the electric company follows a period of agitation by business men for a uniform and modern system of store-front illumination. The feeling has been crystallizing for some time that individuals and community alike would benefit by an improvement in the store-window and sign lighting of individual business houses. The policy of the company is to help advertise the community in which it is located, and it is the pursuance of this policy that prompted the company to offer a minimum charge of $1 per month and an energy charge of 7 cents gross and 6 cents net per kilowatt-hour for all window and display lighting. H. R. Smith is district superintendent of the company.

**Boston, Mass.** — Eight electric companies under the management of Charles H. Tenney & Company added to their lines 5,273 newly wired old houses during 1922, the total number of outlets involved being 82,834. The cost of this wiring was $551,798, or $6.66 per outlet. The work was financed by various plans, including loans by local banks, central-station credit, contractor-dealer credit and the Morris plan.

**Los Angeles, Cal.**—Plans of the commercial department of the Southern California Edison Company call for the connection during the year of thirty thousand new homes which will use Edison service. This does not include the many thousands of new consumers taking service from distributors who buy service from the company wholesale. On the customary ratio of five to one this means that 150,000 people will join the ranks of consumers in one year.

ELECTRO-THERAPEUTIC EQUIPMENT ON DISPLAY IN NEW YORK EDISON SHOWROOM

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Rebuilding of Boiler Plant Reduces Coal Consumption More Than One-Half.*—A modern boiler plant containing six water-tube boilers varying in size from 4,000 sq.ft. to 5,000 sq.ft. of heating surface was built on the site of an old overloaded plant containing fifteen boilers, without interruption to service. It was found that eight of the old boilers were in good condition, and these were rebuilt and enlarged by placing another deck of tubes below the old ones and connecting the headers by short nipples. Purchasing two new boilers made ten available, six of which have been installed, and room has been left in the plant for the installation of the remainder when they are needed.—*Power*, April 10, 1923.

*Interior Treatment of Boiler-Feed Water.*—A. J. Loppin.—Though it is generally best to treat hard make-up water before it is sent to the boilers, special conditions may warrant the use of treatment within the boiler. Whether the exterior or interior treatment should be used depends upon the conditions prevailing at the plant under consideration. It depends upon the amount and kind of scale-forming ingredients in the water, the amount of make-up, water used, the course of the water from its source to the boiler, the period of operation of the boiler, the use of the steam, comparative first cost and maintenance cost for each system, type of boiler, rate of evaporation, pressure, load maintained, etc. The effect of each one of these factors on the final selection is considered.—*Power*, April 3, 1923.

## Generation, Control, Switching and Protection

*Differential Relay for Protection of Three-Phase System.*—R. J. Jensen.—The author describes a system of relays designed by himself for the new power station in Copenhagen. The fundamental feature of the new relay is that the unbalance itself, and not the entire load, is used to actuate the relay. This gives uniform sensitiveness for all conditions of load. The two phases to be controlled are carried into the primary windings of a transformer. To one of these primary circuits are added a resistance and an inductance which are dimensioned so that the current in this phase is displaced 60 deg. with reference to the other phase. The secondary winding is connected to the relay. The voltage induced in this winding is dependent only on the unbalance between the two phases since the balanced parts are neutralized.—*Teknisk Tidsskrift*, Jan. 24, 1923.

*Magnetomotive Forces Produced by Single-Phase and Polyphase Windings.*—R. D. Archibald.—A description is given of a simple method of showing the variation in magnetomotive force of a single-phase alternator winding by the shadow of a vane attached to a rotating spindle. The application of the same principle to the case of polyphase windings and the method of arriving at the position and dimensions of the vanes are explained. An apparatus is described which is arranged to show the magnetomotive force produced in the air gap of an induction motor by the stator and rotor windings under load conditions, with the rotor either stalled or revolving.—*Journal of Institution of (British) Electrical Engineers*, March, 1923.

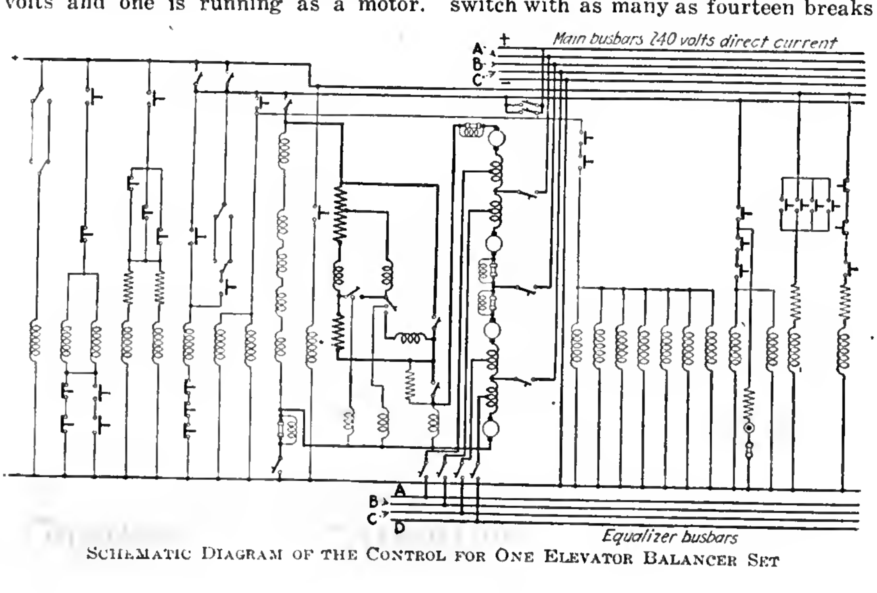
## Transmission, Substations and Distribution

*Automatic Balancer Substation for Elevator Service.*—M. A. Whiting.—In the multivoltage system power is supplied to the elevators from five main buses (see accompanying diagram) which provide four accelerating steps for the elevator motors of 60 volts per step. Voltages for the four-step buses are individually supplied by the four units of the balancer sets acting cumulatively in turn. Considering the acceleration of one motor only, on the first step, say the motor is connected from the plus to the A bus, then one unit of the balancer is supplying 60 volts to the multivoltage bus, and the three others are motoring. On the second step the elevator motor would be connected from the plus to the B bus. Under this condition two units are in series, generating 120 volts, and two are motoring. On the third step three units in series are generating 180 volts and one is running as a motor. When full elevator speed is reached the elevator motor is supplied directly by the 240-volt bus. When this condition obtains the balancers float across the line idle unless the current becomes unbalanced for any cause, in which case the set will make up the discrepancy. This arrangement takes care of the service while imposing the least practical load on the balancers.—*Power*, March 27, 1923.

*Grounding Cable on Overhead Lines.*—H. Behrend.—Investigations of the author on experiences with a grounding cable over an overhead line on systems of 50,000 volts or more indicate that the protective value claimed for such a cable is being considerably overestimated. In case of a ground on the line through a steel tower the danger of a high potential on this one tower is greatly diminished by a cable connecting all the towers. But this, the author claims, is the only positive advantage of a grounding cable, and it could be accomplished far better by laying out a bare underground cable connected to every one of the towers. The cost of the usual overhead grounding cable is about 10 per cent of the cost of the transmission line, an amount which is entirely too high to be paid just for the purpose of diminishing the ground resistance.—*Elektrotechnische Zeitschrift*, March 22, 1923.

## Units, Measurements and Instruments

*Tests on Oil Switches.*—G. Brühlmann.—In several large power stations where up to 32,000 kva. of energy was available short-circuit tests were made on oil switches and their performance was studied. The paper contains a very detailed report of these tests, including several oscillograms. The tests comprised investigations of the influence of multiple breaks, the generated gas pressure and the duration of the arc under oil. The tests seem to indicate that a division of the rupturing arc into a number of smaller arcs lessens the difficulties of the opening process, but that this benefit is not so pronounced in low-voltage switches as it is in types for very high voltages. A switch with as many as fourteen breaks



Schematic Diagram of the Control for One Elevator Balancer Set

per phase was tested and compared with one of only four breaks per phase. With three and one-half times as many contacts the duration of the rupturing arc was reduced only one-half, the sum of the arc lengths increased 25 per cent and the gas pressure generated rose from 4 atmospheres to 6 atmospheres. The excess cost of such a large number of contacts is therefore not warranted. Of considerable interest are tests made on a 35,000-volt oil switch with energy for the test delivered from a specially designed 12,000-kva. steam turbo-generator. Reaching a crest value of about 25,000 amp. short-circuit current, it was found from the oscillograms taken that the switch contacts opened and closed again three times before the intended opening. This was attributed to a lifting of the contacts due to the large dynamic forces acting upon them, and it resulted in a redesign of the contacts. A locomotive switch designed for 16⅔ cycles and 15,000 volts was tested with 16,000 volts and 3,250 amp., which would correspond to a three-phase rupturing capacity of 155,000 kva. After clearing the short circuit eight times at intervals of four minutes and one minute the breaker remained in perfect condition, it being the only breaker of several submitted for test by different manufacturers to stand up under the test. As a result the Federal Swiss Railways selected this type of switch as the standard equipment for its electric locomotives. The article contains a number of interesting photographs of modern Swiss oil switches designed for voltages up to 150,000. — *Brown-Boveri Mitteilungen*, April, 1923.

## Motors and Control

*Application of Electricity to the Printing Industry.* — Printing machinery is now almost exclusively driven by electric motors, and as a direct result of this development control apparatus has been highly developed. Raised-surface or typographic printing is the particular field covered in the article. This includes newspaper printing, magazine printing and the vast amount of work done by book and job publishing houses. The article pertains to the printing industry in Canada.—*Electrical News*, April 1, 1923.

SOURCES OF POWER FOR THE PRINTING INDUSTRY IN CANADA

*Speed Control of Polyphase Motors.* —Gordon Fox. — An exhaustive and complete analysis of the factors involved in the operation of this type of motor is given. A classification of various systems of control and a description of each system are included. Three methods of speed control function through change of synchronous speed. These are the variable-frequency system, the multispeed motor and the cascade set. Three common control methods depending upon variation of the amount of slip are secondary resistance or rheostatic control, primary voltage control and dynamic control. Under "dynamic control" fall the Kramer, Scherbius and frequency-converter systems.—*Blast Furnace and Steel Plant*, March, 1923.

## Heat Applications and Material Handling

*Recent Developments in the Arc-Welding Field.*—W. L. Warner.—This is the annual report on electric arc welding presented before the American Welding Society at the annual meeting on April 25. The paper includes standard tests for welds, welding wire specifications, arc welding of cast iron, welding oil storage tanks, rail joints and various other applications, welding monel metals, manufacture of pure iron, arc-welding apparatus and suggested research activities.—*Journal of American Welding Society*, April, 1923.

*Methods of Handling Materials in the Electric Furnace and the Best Type of Furnace to Use.*—F. E. Brooke.—The author discusses the design of various electric furnaces, such as the plain box type, the special box type, the car type, the recuperative and continuous furnaces, and refers to their advantages and disadvantages. Attention is drawn to the method of handling materials for these furnaces so that a uniform temperature and high furnace efficiency may be maintained.—*Paper presented before the American Electrochemical Society, New York*, May 3-5, 1923.

## Illumination

*Influence of Paint on Interior Illumination.*—R. L. Hallett.—This paper briefly discusses the illumination of building interiors, particularly from the standpoint of secondary illumination or the illumination obtained by reflection of light from walls and ceilings. The effect of color and surface finish on reflection of light is discussed, and information is given concerning the reflection properties of paint made with various materials. Durability of paint films as affecting reflection of light is referred to, and the effect of the opacity of pigment as influencing reflection of light is brought out. The results of experiments showing the reflection factors of various kinds of paint and of the durability of paints of different composition are given.—*Transactions of the I. E. S.*, April, 1923.

## Electrophysics, Electrochemistry and Batteries

*Influence of the Base Metal on the Structure of Electrodeposits.* — W. Blum and H. S. Rawdon.—If copper is deposited electrolytically upon cast or rolled copper which has been cleaned with alkali, the structure of the base metal does not apparently affect that of the electrodeposit. If, however, the surface of the base metal has also been treated with nitric acid, the electrodeposited copper possesses both the crystal form and the orientation of the base metal.—*Paper presented before the American Electrochemical Society, New York*, May 3-5, 1923.

## Telegraphy, Telephony, Radio and Signals

*Magnetic Shunts in Telephone Receivers.*—H. Carsten.—The influence of a magnetic shunt across the pole pieces of the permanent magnet in a telephone receiver upon the sensitiveness of the telephone is investigated by experiments and calculation. It is found that the effect of the magnetic shunt depends largely upon the density of the field of the permanent magnet. An actual increase of sensitiveness can be obtained only with very high magnetic flux densities, for which the generally used magnets are insufficient. It is claimed that the addition of a shunt to magnets used today in modern telephone factories has therefore no advantage. — *Elektrotechnische Zeitschrift*, March 22, 1923.

*Tuned Radio-Frequency Amplification with Neutralization of Capacity Coupling.*—L. A. Hazeltine.—Tuned radio-frequency amplification is based on the general principle that electrostatic or capacity coupling between two circuits behaves like electromagnetic coupling in that it may be reversed and may be reduced to zero. This is accomplished by balancing one capacity against another. To attain the balance condition it is generally necessary to reverse the phase of a voltage, and this involves the use of a transformer in addition to the capacities. The circuit is a simplification of previous circuits and not an elaboration. It eliminates a previously existing disturbing feature and so gives pure relay amplification. —*Q.S.T.*, April, 1923.

## Miscellaneous

*Newer Aspects of Ionization Problems.*—H. S. Taylor.—A résumé is presented of some recent work by Born, Fajans, Haber and others on the problem of energy changes accompanying the conversion of some solid crystalline substances and of the hydrogen halides into dissolved ions. An outline is given of the concepts of lattice energy and of the electron affinity of halogens, the quantitative side of the problem receiving detailed consideration. Small modifications of the earlier calculations have been made whenever newer material of a more reliable nature seemed to be available.—*Paper presented before the American Electrochemical Society, New York*, May 3-5, 1923.

## English and Engineering

A Volume of Essays for English Classes in Engineering Schools. Edited by Frank Aydelotte, president of Swarthmore College. Second edition. New York: McGraw-Hill Book Company, Inc.

The function of English in technical education is, as President Aydelotte points out in his admirable introduction, twofold—"in the first place, to train students to express themselves in writing and speaking, not merely grammatically, but with order, force, sincerity and such charm as their natures will allow; in the second, to furnish something of the liberal, humanizing and broadening element which is more and more felt to be a necessary part of an engineering education." The two aims, the writer continues, are in reality closely connected and by them the outline and arrangement of his anthology have been dictated. The range from which material has been drawn, already a wide one in the first edition of six years ago, has been made even wider, embracing writings which extend from the works of John Ruskin, John Stuart Mill and Robert Louis Stevenson to those of living engineers and the advertisements of manufacturing companies. The book is divided into six parts, under each of which from two to nine essays or discourses are grouped without comment or notes. The first section, entitled "Writing and Thinking," is "an attempt to make the student see the dependence of writing on thinking, to impress upon him the first of all principles of good writing, that he must have something to say." The second and third sections deal with the profession of engineering and the demands which it makes on the engineering schools. The titles, "Pure Science and Applied," "Science and Literature" and "Literature and Life," epitomize the scope of the remaining sections.

President Aydelotte's collection, even though many refulgent masters of prose are necessarily unrepresented, is abundantly adapted to the classroom study of the engineering pupil who has heard and practiced correct speech from early childhood, who has an innate love of literature and who can feel the charm of words and delight in their nice uses and distinctions. Unfortunately, such students are comparatively few in our technical schools. Has the editor of this volume, one wonders, a plan by which the large majority of engineering undergraduates—boys of deficient elementary education, from homes where letters are little cultivated, who have turned to engineering just because they do *not* care for books or writing, but do love to use their hands and their wits in practical and productive arts—can be taught, not to compose treatises in masterly English, but, when occasion arises, to tell a plain, unvarnished tale of facts and experience in a clear, concise and grammatically correct manner? Will there come a day when a technical graduate as profoundly ignorant of rhetoric and as slovenly in syntax as hundreds of them are today will be as much a source of amazement as one ignorant of higher algebra or the use of logarithms?

## Die Technik der Elektrischen Messgerate

By Dr. George Keinath. Munich and Berlin: R. Oldenbourg. 448 pages, 372 illustrations.

Many authors keep abreast with the rapidly advancing art of instrument building by the frequent issue of new editions, so that there is really no lack of complete and up-to-date books on this subject. But all of them have one shortcoming in common in that they either surround a purely technical description of the construction of the instruments with too much theoretical matter, or else they neglect the constructive part of the instruments altogether. Dr. Keinath has written a book for the practical engineer and has introduced only such theoretical and mathematical explanations as are essential. The chapters on registering and "hot-wire" instruments contain details and test results found nowhere else in electrical literature. The author is connected with the Siemens & Halske company, which accounts for the fact that instruments and design of this firm are mentioned more frequently than others. By adding fifteen or twenty pages of details on the existing designs or oscillographs and apparatus for the measurement of the magnetic properties of iron the book could be made complete. A. PALME.

## The Essentials of Transformer Practice

By Emerson G. Reed. New York: D. Van Nostrand Company. 257 pages, illustrated.

A thoroughly readable and thoughtfully prepared treatment of the theory, operation and design of transformers. While meant primarily for the student and operating engineer, the treatment is fundamental and adequate for the specialist and designer. Much original material on transformer iron and insulation is contained in the text, the discussion of transformer heating being particularly good. The design element is subordinated to the fundamental physical phenomena and the use of mathematics is reduced to a minimum. General relations, polarity, reactors, losses, efficiency, transformations and regulation are discussed with a splendid perspective. The make-up, style and material combine to make this book a noteworthy addition to transformer literature.

## Advanced Laboratory Practice in Electricity and Magnetism

By E. M. Terry. New York: McGraw-Hill Book Company, Inc. 258 pages, illustrated.

A course in electrical measurements is given to electrical students in many schools, and for such courses this book of Dr. Terry is admirably adapted. It contains a carefully selected amount of material which is presented in teachable form. It recognizes the changes in the electrical art by adding to the usual measurements carefully prepared chapters on the discharge of electricity through gases, radio activity and thermionics. The fundamental principles of transient phenomena are treated in some detail. The arrangement of the book is good and well adapted to the laboratory method of teaching. Much of the material is new, and the work should be well received by the colleges and prove interesting to many engineers engaged in measurement work.

## Electric Toy Making

By T. O'Conor Sloane. New York: Norman W. Henley Publishing Company. 249 pages, illustrated.

Practically every type of amateur application of electricity is treated in the twenty-first edition of this book. It is the type of book that boys delight in having and has some very useful designs for more mature students.

## Engineer in Public Affairs

**Four Founder Societies in New York Hear Discussion of the Part He Should Play**

A MEETING under the auspices of the four founder societies of the United Engineering Society was held in the Engineering Societies Building, New York City, on Tuesday of this week to discuss "The Engineer in Public Affairs." Senator Stirling of South Dakota, who was to have made an address, was unavoidably absent. Gano Dunn, president of the J. G. White Engineering Corporation, who occupied the chair, declared that the engineer must be an all-around man before he can reach the heights of his profession. The increasingly essential relation of engineering works and structures, engineering operations, engineering conceptions and even engineering terms and habits to the daily life of the people of the United States has been so marked, he said, that engineering of itself has been taking a greater and greater part in public affairs, and if the engineer cannot keep pace with his subject, then certainly he is unworthy of the name. At the same time, Mr. Dunn recognized the possibility of overemphasizing the desirability of direct participation by engineers in public affairs. The proper line of demarcation was one of the things for consideration.

Admiral John K. Robison, engineer-in-chief of the United States Navy, told of engineering in the navy and made a strong plea for that branch of the nation's defense. The navy's problems, he said, are largely engineering ones.

President Frank B. Jewett of the American Institute of Electrical Engineers took Senator Stirling's place on the program and urged, as did Mr. Dunn, that all engineering bodies unite in support of the Federated American Engineering Societies, burying their individual points of view where these conflict.

## New York Legislature Passes Ferris Amendment

Before adjournment last week the New York State Legislature passed for the second time the Ferris amendment to the state constitution, referred to last week, which authorizes the use of not to exceed 3 per cent of the lands of the forest preserve for the building of transmission lines and the erection of power and generating stations for electrical development of state-owned water powers. The amendment will go to the people for ratification at the general election in November.

Five amendments to the Public Service Commission law were passed and are now in the Governor's hands. Two of these affect gas companies, one of them restoring "dollar gas" in New York City; two affect steam and electric railway companies, one of them ordering all steam tracks within New York City to be electrified by January, 1926, and the fifth amends sections of the law relative to the verification and filing of annual utility reports.

## Public Service of New Jersey Places Big Orders

Orders have been placed by the Public Service Corporation of New Jersey for the initial installation of 200,000 hp. for its new steam station at Kearney, N. J. The General Electric Company is to build three 40,000-kva. units for this plant, and the Westinghouse Electric & Manufacturing Company two units of the same rating. Ultimately ten units will be installed, giving the station a rating of 400,000 hp. Stoker-fired boilers will be used.

## Annual Business Meeting of A. I. E. E.

The annual business meeting of the American Institute of Electrical Engineers will be held at the Engineering Societies Building, New York, next Friday, May 18, at 4 p.m. Results of the annual election of officers will be announced and the report of the board of directors presented.

## Ford May Develop Many Michigan Power Sites

A bill permitting private corporations to condemn 25 per cent of the land necessary to develop water-power sites was passed by the State Legislature of Michigan last week and was reported to be likely to receive the Governor's signature and become law. Its passage may lead to development of water-power sites all over the state by Henry Ford. The Ford interests, it is said, exerted all the pressure at their disposal to get the bill through.

The bill as it passed the House carried an amendment introduced at the request of Governor Groesbeck which stipulates that the state shall retain title to all lands condemned and lease them to private corporations.

## Southern Power Halts Work

**Immediate Construction of Catawba River Project Abandoned—High Costs the Obstacle**

AS FORESHADOWED in the ELECTRICAL WORLD for April 28, page 995, the Southern Power Company has definitely abandoned its expansion program, for the present at least, on account of increased costs of labor and electrical equipment. Announcement to that effect was made at Charlotte, N. C., last Saturday by J. B. Duke, president of the company, who said that the company found it impossible to build at today's costs and earn a reasonable return at the rates allowed. For several weeks officials and engineers of the company have been going over building plans and consulting with equipment manufacturing concerns and contractors. Three weeks ago it was semi-officially announced that prices were so high that it seemed highly probable that the company would have to halt its building program. Further conferences only confirmed previous ones as to costs, and the definite announcement of abandonment of the program was made.

### Will Complete Projects Under Way

Following a period of inactivity during and immediately after the war, the power company last year began building again. Two large projects were started, one at Great Falls, S. C., developing 60,000 hp., and one at Mountain Island, N. C., developing 80,000 hp. The Great Falls plant is now complete and the Mountain Island plant will be completed this year. In addition to this hydro-electric construction, work was begun on two steam auxiliary plants, one of 40,000 hp. at Mount Holly, N. C., and one of 20,000 hp. at Eno, N. C. Work was also begun on 200 miles of transmission lines. This work will all be completed this year. As already announced in these columns, it was the purpose of the company to begin work on at least one more plant, and a site on the Catawba River, near Rhodhiss, N. C., was selected. The plans called for the development of 50,000 hp., and had a halt not been called this power would have been ready for industrial use by early next fall and would have taken care of present accumulated demands on the company, amounting to about 25,000 hp., and provided a surplus for future demands.

Rates in North Carolina are fixed by the State Corporation Commission. The present power rates were fixed three years ago and were based, it is

said, on original costs of the plants existing at that time. These plants were built when everything was much cheaper than now and were also built at the best sites; that is, where power could be developed at the least cost.

In addition to the increased labor and equipment costs, another item of expense to the company which, it is maintained, has more than tripled in the last few years is land, which the company has to acquire by the thousands of acres adjacent to and above its dams.

## Byllesby Acquires Oklahoma Utilities

Thirteen towns and cities in Oklahoma, with a combined population of 50,000, were added to the lines of the Oklahoma Gas & Electric Company this week upon the absorption by the H. M. Byllesby Company, Chicago, of the Shawnee Gas & Electric Company, the Oklahoma Light & Power Company, supplying electricity in Ada, Sulphur, Paul's Valley, Holdenville, Seminole, Maud, Harjo, Konawa, Francis, Roff and Maysville, and the Southern Oklahoma Power Company, which has a steam turbine station at Byng rated at 8,000 hp.

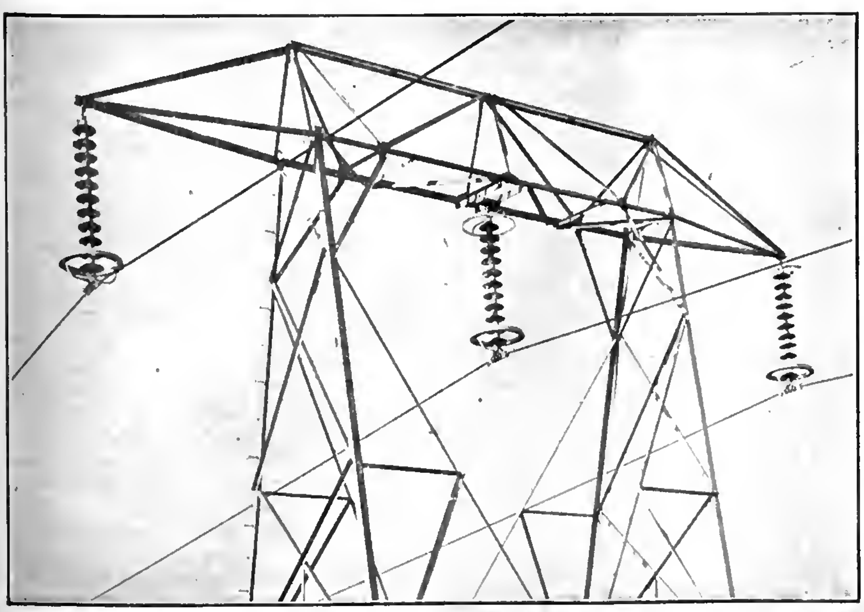
Most of these communities are interconnected by 123 miles of transmission lines, with 30 miles of new lines under construction. Eventually these properties may be connected with the 400-mile transmission system of the Oklahoma Gas & Electric Company, which now serves forty-nine cities and towns with a population of 277,000. The newly acquired properties serve 7,489 electric customers.

# Transmission at 220,000 Volts a Fact

### Big Creek Line Was Synchronized with Southern California Edison System Early Last Sunday Morning—A Triumph of Years of Research—No Hitch of Any Kind Is Experienced

At 6:12 O'CLOCK on the morning of May 6, 1923, the switches on the Big Creek lines of the Southern California Edison Company were closed and 220,000-volt transmission became an accomplished fact. Reports from California say that everything came off according to schedule with no hitch. The event marks the culmination of years of research, experiment and study of the problems of higher-voltage transmission by some of the most prominent electrical engineers in the profession, and to the electrical industry and the scientific world the day will go down in the annals of electrical progress as one of the important dates.

The photograph represents a suspension tower on one of the Big Creek transmission lines. These lines have been operating for some time at 150,000 volts. Before being changed over to 220,000-volt operation additional insulation units were added, making a total of eleven units on suspension and thirteen on dead-ends. Cast-aluminum shield rings having a diameter of 28 in. are used to distribute the electrostatic stress uniformly along the insulator strings. The conductors are 605,000-circ.mil aluminum, and each line has a capacity of 125,000 kw. at 220,000 volts. Auto-transformers forming a part of the line are used at each end except at Big Creek No. 8 power house, where 220,000-volt transformers were provided at the time the plant was built.



Cast-Aluminum Rings (28 In. Diameter) Make Electrostatic Distribution Across Disks Uniform

## Power Board Activities

### Competition for New River Rights in West Virginia—Alaskan Permits and Timber Purchases

Owing to the fact that the market for electric power in southern West Virginia and northeastern Virginia is growing at a compounded rate of more than 20 per cent per annum, a determined fight before the Federal Power Commission is in prospect for the power site near Hinton, W. Va., on New River. The contending applicants are the Virginian Power Company, which has headquarters at Charleston, W. Va., where it is operating a 60,000-hp. steam plant, and the Appalachian Power Company, whose activities center at Roanoke, Va. The latter company owns most of the flowage lands required and is now contemplating pushing a development which calls for the construction of six plants on New River. The two lower plants would be in direct conflict with the application of the Virginian Power Company.

The Home Power Company, a public utility operating in Skagway, Alaska, has received a preliminary permit from the commission for a small project on the North Fork of the Skagway River. This development is made necessary by the fact that the present source of power is interrupted before the end of winter by the freezing of the stream. A license has been authorized for L. H. Carvey covering a small project on Archangel Creek, 70 miles north of Valdez, and another to B. A. Garver of Seattle covering two minor projects on Big and Little Kanatak Creeks, near the town of Kanatak, Alaska.

#### Policy on Alaskan Permits

The Federal Power Commission and the Forest Service are about to agree upon a policy of co-ordination to apply in connection with combined power and pulp projects in Alaska. The power commission thus far has been granting preliminary permits in such cases with a requirement that the permittee shall purchase the necessary timber for his operations from the Forest Service. The effect of this plan is to limit competition for the sale of the wood, which led the Forest Service to propose that the timber be advertised for sale at the same time the power commission advertises the application. In this way the rights can be extended so as to safeguard better the public interest, it is contended. This plan may slow up initial action on the application, since timber sales must be advertised for four months, whereas applications for power rights need be advertised for only two months.

The license issued to the Wisconsin-Minnesota Light & Power Company, which required the stocking of its reservoir with muskellunge fish, has been amended to eliminate that provision.

Questions involved in the conflicting applications in the Little Falls-Pike Rapids case will be discussed at a public hearing to be conducted by the commission on June 7.

## Insull Dinner for Merz

### Visiting Engineer Expresses Views on Electric Developments and Tells of Progress in England

SAMUEL INSULL gave a dinner to Charles H. Merz of London at the Edison Restaurant, Chicago, on the evening of May 2, at which more than two hundred utility men and others were present. Mr. Merz is the head of the well-known engineering firm of Merz & McClellan, consulting engineers for the Commonwealth Edison Company, and, with some members of his staff, is in this country investigating the present status of electric power development in the United States. Mr. Insull, in introducing Mr. Merz, referred to him as having been connected with large electric power developments the world over and as an authority on the economical production and distribution of electrical energy as well as an engineer of great distinction and high ideals.

In responding, Mr. Merz spoke of the wonderful development attained by the electric power industry as shown by the fact that work is actually under way on a million-horsepower station. The reference, undoubtedly, was to the Crawford Avenue station of the Commonwealth Edison Company, for which Merz & McClellan are consulting engineers. Mr. Merz went on to sketch electric power conditions in Great Britain from the days of Joseph Chamberlain, the British statesman who had so much to do with the "municipalization" restrictions that have characterized this development. He described the present method of control by electricity commissioners in Great Britain and referred also to the modern and extensive electrical development in the Newcastle-on-Tyne region under private ownership. Recent electric power development undertakings in Australia and South Africa were mentioned, and Mr. Merz told how in the former country lignite or brown coal is being used for fuel.

In relation to railroad electrification the speaker brought the cheering news that the English companies favor centralized energy rather than the building of their own generating stations. On the general subject of massing the production and distribution of electrical energy Mr. Merz expressed himself in entire agreement with the ideas, promulgated many years ago, of Mr. Insull.

#### Underground Distribution Prevails

Underground distribution of electrical energy is highly developed in Great Britain, contrasted with the more usual distribution by overhead wires in this country. Even electric services to customers in small communities are underground. Thus distribution problems in Great Britain are rather different from those of the United States. The distribution is more likely to be regarded as a system separate from the production end. Outdoor switching stations are almost unknown. The 230-volt lamp is in almost universal use and has some advantages compared with the 115-volt lamp of this country.

The United States has seen one important advance in generating station practice which has no counterpart in Great Britain at present, the speaker said, and that is the use of very large steam boilers. For the future he believed that progress would be in the line of greater interconnection, more centralization, increase in the size of generating stations and higher steam pressures. With the large steam turbines, say of 50,000 hp. and upward, now in use, economies are obtained comparable with the highest efficiencies of internal-combustion engines. The latter at present cannot be made in very large sizes and are not to be had in units of more than 5,000 hp. This is not big enough for great modern generating stations, although in smaller plants the internal-combustion engine has obvious advantages, being economical in fuel and in labor. It should be watched by generating-station designers as it may be developed so that it will be available in larger sizes.

Mr. Merz concluded by declaring that while engineers must always work for the greatest economy in electric power production, they must never forget that to obtain this security and reliability must not be sacrificed.

## Consumers' Power 100,000-Kw. Plant

### Saginaw River Station to Use Cast-Iron Blocks in Place of Furnace Brickwork, Thereby Increasing Heat Absorption—Hydraulic Stokers—Water Sluicing of Ashes

THE Consumers' Power Company, Jackson, Mich., has started the construction of a 100,000-kw. steam generating station at Zilwaukee, on the Saginaw River, 3 miles north of Saginaw. The company has available an extensive acreage of land along the bank of this navigable river, so that in the future coal may be supplied to the plant by boat. At the present time, however, coal will be received by rail over the Grand Trunk and Michigan Central railroads. The initial installation will consist of two 25,000-kva. General Electric steam turbines. Operation is expected to start with the first unit about Dec. 1, and the second unit will, it is thought, be ready next March.

Each turbine unit will have two B. & W. boiler units, each having 8,870 sq.ft. of steam-heating surface and rated at 900 hp. These boilers will be fired by American Engineering Company type K underfeed stokers of a hydraulically driven type, using a Hele-Shaw pump system. The stokers will have a double row of clinker crushers. The steam pressure will be 375 lb. with 250 deg. F. superheat. A double bank of the Green Fuel Economizer Company's vertically baffled cast-iron economizers will be mounted directly above the boilers. They will have 8,500 sq.ft. of heating surface. Superheaters of the radiation type will be installed in the back walls of the furnaces by the Power Specialty Company.

The chief feature of the boilers will be the substitution of cast-iron blocks furnished by the Power Specialty Company for parts of the furnace lining. Through these cast-iron blocks water-cooled steel tubes will run which will circulate water at the same pressure as the boiler. It is expected that these water-cooled furnace linings will generate steam to correspond to a heat-absorption rate of 60,000 B.t.u. to 80,000 B.t.u. per square foot of exposed surface per hour. The building will be constructed of waterproof reinforced concrete up to any possible flood stage of the Saginaw River. Above that level the building will be a steel-supported brick structure. Steel stub stacks will be used, one for each boiler.

The coal-handling equipment will consist of a track hopper and an automatic vertical skip hoist, which will discharge the coal through crushing and weighing apparatus upon a shuttle belt conveyor, which will travel on a truck over steel-plate bunkers. Excess coal will be spouted by gravity from the skip-hoist tower back to the yard and spread out into storage by a drag scraper.

#### Ash Handling by Sluicing

Ash removal will be handled by means of a concrete sluiceway directly below the boilers supplied with water from the circulating system of the main condensers. As the ashes are ground through the clinker crushers of the stokers, they will drop to the secondary grates, from which they can be dumped by hand into the sluiceway. This sluiceway is to feed into a well so that the ashes may be raised by motor-operated manganese-steel-lined dredging pumps to a wooden launder which will carry the ashes mixed with water to the dumping grounds. These pumps will be capable of handling lumps of clinkers up to 8 in. in diameter. A grizzly will protect the pumps from clinkers larger than this size.

The make-up water will be purified by means of Griscom-Russell evaporators connected between the bleeders of the eighth and eleventh stages of the turbines. Each evaporator will have a maximum capacity of 10,000 lb. per hour. A condensate storage reservoir will be provided between the foundation walls under the boiler-room basement. This arrangement of evaporators eliminates a number of pumps and other auxiliaries generally found with a low-pressure evaporator plant. In this case the evaporator feed pump is also eliminated, as the water will feed to the evaporators by gravity from the cold-water house-service supply tanks. Deaëration of feed water will be accomplished by admitting all the con-

densate which has been exposed to the air in storage back into the system through the main condensers, which will have hot wells of special design. This will deliver the condensate practically free from dissolved air and at a much higher temperature than that corresponding to the pressure of the vapor in the condenser. Air for combustion will be admitted to the building through louvers and heaters in the top of the boiler room and drawn down through ducts, carrying with it waste heat from the boiler-room radiation losses into the forced-draft fan room. After passing through the fans on the way to the stoker wind boxes, the air will be preheated to a temperature of 250 deg. to 300 deg. F. by means of hot water and steam bled from the main units.

Since the power house will be nearly 800 ft. from the river, long intake and discharge circulating water ducts will be necessary. Two 22,000-g.p.m. pumps and one 35,000-g.p.m. pump will be built to operate the first two condensers. The Ingersoll-Rand condensers will be of the pear-shape type, being built for one pass only with ⅞-in. tubes, and each will have a surface of 14,250 sq.ft., excluding the coolers.

### NOVEL FAN CONTROL

What is believed to be an original arrangement of motors and controls for the forced-draft and induced-draft fans has been developed. Directly connected to each forced-draft fan there will be a 25-hp., 720-r.p.m. and a 100-hp., 1,200-r.p.m. motor. These are to be 440-volt alternating-current slip-ring motors with the 720-rp.m. motor designed for safe overspread at 1,200 r.p.m. Each motor will have its controller, of the motor-operated drum variety, and the controllers will be so connected and interlocked that by the mere operation of one push-and-pull switch on the boiler-control board any fan speed from 360 r.p.m. to 1,200 r.p.m. can be obtained. When the drum controller of the small motor has reached its top speed, a contactor will automatically cut this motor off the power circuit, and another contactor will connect the larger motor, whose controller will then accelerate up to the maximum speed with the small motor coasting. The reverse operation is similar. Flashing lights will indicate each step of each controller. Each induced-draft fan is driven by a 40-hp. and a 150-hp. motor operated similarly, the 40-hp. motor being connected by a chain drive while the large motor is directly connected to the fan shaft. Fan speeds of 225 r.p.m. to 900 r.p.m. are provided for. The small motors will furnish the necessary draft for 70 to 80 per cent of the running time, the large motors being called upon only when the boilers are operated at the very highest ratings.

The turbines will generate at 12,000 volts, which will be stepped up to 24,000 volts by means of auto-transformers directly connected to each turbo-generator. These auto-transformers will be installed in the outdoor substation with no switch between them and the generators. Differential relay protection will be provided around the entire unit of generator and auto-transformer, so that a failure in either the generator, the connecting cables or the auto-transformer will trip the switch connecting the unit to the 24,000-volt bus, open the generator field and close the throttle.

The generators are to have an entirely self-contained air-cooling system, which will circulate the air past water-cooling coils, the total volume of air in the system being extremely small. The volume of air, in fact, will be so small that in case of an incipient fire in the generator windings the oxygen would hardly support combustion for the small amount of dust which might be present in the windings. On this account no water, steam or other fire-fighting equipment is to be provided.

Each exciter is to be a 110-kw., 250-volt shunt unit directly connected to the turbine shaft. Bracketed and directly connected to the end of this exciter will be a small 2-kw., 125-volt machine to excite the field of the 110-kw. exciter. No main series-field rheostat is provided, nor will a Tirrill regulator be used. The exciter rheostat is to be motor-operated and consist of two sections, the first section cutting in resistance in the field of the main exciter and the second section cutting in resistance in the 2-kw. generator field. There is no spare excitation whatsoever provided, although in case of trouble with the 2-kw. machine the main exciter fields could be readily excited from the station control battery, which has a voltage of 125.

### OUTDOORS EQUIPMENT

Following the general practice of the company for the last ten years, all of the switching and transforming equipment will be installed in an outdoor substation erected adjacent to the steam plant. This will include the auto-transformers, the station power transformers, the step-up transformers for the 140,000-volt system and 24,000-volt and 140,000-volt buses and switching equipment. The 24,000-volt switches will be of the General Electric type KO-39B variety, rated at 50,000 volts.

The station power transformers are to be three 500-kva. self-cooled transformers stepping down from 24,000 volts to 480 volts, one bank supplying all the station auxiliaries for the first two units. Future units will obtain station auxiliaries from a second station power bank. To insure as much as possible against transformer failure, the station power transformers are to be built to 50,000-volt specifications.

The 140,000-volt substation will consist of a 45,000-kva. bank of transformers stepping up from 24,000 volts to 140,000 volts, together with switching equipment for the 140,000-volt lines. It is planned to install a duplicate 140,000-volt bus with electrically operated remote-control disconnecting switches connecting the line and transformer switches to either bus. In addition, there will be a bus-tie oil circuit breaker provided with electrostatic synchronizing equipment to enable the two buses to be synchronized. This outdoor substation will supersede the present indoor station at Zilwaukee, which is a portion of the original 140,000-volt system built in 1911. By means of this 140,000-volt system the energy of the new station will be available generally on the system, which already connects the Au Sable River dams with Flint, Owosso, Battle Creek, Jackson and, through frequency changers, with Grand Rapids and other cities served by the 140,000-volt, 30-cycle system.

The entire engineering and construction of the plant is being carried on by the engineering and construction departments of the Consumers' Power Company, H. F. Eddy, mechanical engineer, and J. H. Foote, electrical engineer, having direct charge of the design and engineering, and G. F. Stecker, assistant manager of construction, being in direct charge of building the station.

## No Change in Control of the Crocker-Wheeler Company

At the annual stockholders and directors' meeting of the Crocker-Wheeler Company, held in New York on Wednesday, May 9, new officers were elected, the selections proving that there will be no change in policy or management because of the death of President Schuyler S. Wheeler. Edmund Lang, who was previously vice-president and secretary, was made president. Arthur L. Doremus was continued as vice-president, and Clarence N. Wheeler, the former controller, was elected to fill the vice-presidential vacancy caused by Mr. Lang's promotion. Herbert C. Petty, formerly assistant sales manager, became secretary and sales manager; Theodore S. Fuller was continued as treasurer, and George W. Bower was made assistant secretary and assistant treasurer. The existing board of directors was re-elected, the vacancy caused by Mr. Wheeler's death being left unfilled for the present. Besides the president and vice-presidents named above, these directors are Edward W. Brown, Hampton D. Ewing, E. B. Humpstone, Frank H. Jones, and Dr. M. I. Pupin.

## F. A. E. S. Makes Appointments to Coal Committee

Appointment of four members of the committee to conduct an investigation into the storage of coal is announced by the Federated American Engineering Societies. They are P. F. Walker, dean of engineering, University of Kansas; S. W. Parr, professor of applied chemistry, University of Illinois; H. Foster Bain, director of the United States Bureau of Mines, and L. E. Young, Union Light & Power Company, St. Louis. The chairman is W. L. Abbott, chief operating engineer of the Commonwealth Edison Company, Chicago.

## Commercial Men Meet

### Hoosier Association Devotes One-Day Session to Appliance Selling, Rural Rates and Refrigeration

SELLING appliances, rural extensions and electrical refrigeration received great attention at the Commercial Section meeting of the Indiana Electric Light Association at Indianapolis on May 3. A. W. Krueger, Edison Electric Appliance Company, answered the question as to whether a central-station company should merchandise appliances in the affirmative, basing his opinion on the experiences of central stations in many localities throughout the West. All electrical dealers, he thought, benefited by the pioneering work of the utility. Wallace O. Lee, Indianapolis, cautioned against price cutting if a utility desired the co-operation of the local contractor-dealers. T. Hatfield, a contractor-dealer, felt that since the utilities were virtually the backbone of the electrical industry, it was perfectly logical for them to handle merchandise, but unless prices were maintained dissatisfaction and jealousy on the part of other dealers would arise. R. Thurman chairman Commercial Section, and F. W. Buck thought that if the field was entered separate merchandising departments should be maintained.

#### New Rural Rates

The newly proposed rural service regulations for Indiana were discussed by Earl Carter, chief engineer of the Public Service Commission. These rules follow those adopted in Wisconsin in that the rural charge is determined by a certain percentage of the total investment. For Indiana this charge is 10 per cent of the total cost of the new general and local construction. Besides this, there are the regular urban minimum and energy charges. Construction is handled under the supervision of the utility that assumes title upon completion of the extensions.

John W. Brockman, Brookville, raised the question of how connection charges for additional customers should be handled once the line had been completed. Mr. Carter said this connection charge was determined by dividing the total cost of the general equipment by the number of customers, and if this charge was higher than the additional cost of the general equipment, the company would refund the difference to the consumers on that line, including the new users.

At the afternoon session D. M. Jones, Schenectady, N. Y., presented the economic side of poor power factor, explaining his subject by concrete examples. C. W. Johnson spoke on the value to central stations of increasing their load by the sale of refrigerators for private residences. By assuming an average residential yearly lighting bill of $19 against a 800-kw.-hr. consumption for a refrigerator which would give a return of $59, Mr. Johnson showed that the refrigerator load was a virgin field which would be an excellent revenue producer. H. E. Crane, Fort Wayne, however, cautioned against too much enthusiasm in selling these machines, thereby forgetting the necessary servicing. He estimated the average daily cost of his own refrigerator at 12 cents.

At the banquet on Thursday evening W. H. Morton, Sanborn Electric Company, Indianapolis, and C. C. Perry, president Indianapolis Light & Heat Company, spoke.

## Will Consider Illuminating Engineering Nomenclature

Thirteen men, consisting of six representatives of producers, three representatives of consumers and four representatives of general interests, constitute the personnel of the sectional committee on illuminating engineering nomenclature and photometric standards, one of the projects officially before the American Engineering Standards Committee. The Illuminating Engineering Society has been named sponsor for this project. The men who constitute this committee, and the organizations which they represent, follow:

American Gas Association, W. J. Serrill; American Institute of Electrical Engineers, A. E. Kennelly; Bureau of Standards, A. S. McAllister; Illuminating Engineering Society, Howard Lyon and G. H. Stickney; National Committee of International Commission on Illumination, Louis Bell; National Committee of International Electrotechnical Commission, C. O. Mailloux; National Council of Lighting Fixture Manufacturers, E. C. McKinnie; National Electric Light Association, C. H. Sharp; Optical Society of America, E. C. Crittenden; American Physical Society, E. P. Hyde; individuals, G. A. Hoadley and M. Luckiesh.

## Electrochemists Discuss Many Furnace Applications

The forty-third meeting of the American Electrochemical Society, held at New York on May 3, 4 and 5, was attended by 250 members and guests. The technical papers of the first day included symposiums on electrode potentials and electrodeposition. On Friday, among other subjects, "Heat-Insulating Material for Electrically Heated Apparatus" was discussed by J. C. Woodson, "Methods of Handling Materials in the Electric Furnace and the Best Type of Furnace to Use" by Frank W. Brooke, "Relation Between Current, Voltage and the Length of the Carbon Arcs" by A. E. R. Westman, and "Electric Furnace Detinning" by C. E. Williams, C. E. Sims and C. A. Newhall. Saturday was given over to papers on the production and application of the rarer metals.

J. W. Hinckley of the National Carbon Company was elected president of the society for the ensuing term. E. G. Acheson was elected an honorary member.

## Electric Truck Promotion

### Interested Bodies Unite for a Co-operative Program with Many Ramifications

NO LESS than twelve associations, groups of associations or groups of individuals are united in the "electric truck business development program" recently formulated in conference by representatives of these associations and to be put into effect through the Joint Committee for Business Development. These twelve bodies include, in addition to the committee just named, the Electric Motor Truck and Car Bureau, the Commercial Section and the geographic divisions and state associations of the National Electric Light Association; the Associated Manufacturers of Electrical Supplies, the Society for Electrical Development, the Electric Truck Association of New York, local electrical leagues and three groups of manufacturers directly concerned, namely, makers of electric trucks, of industrial trucks and of storage batteries.

The aims of the program are (1) to inform and interest the electrical industry generally regarding the possibilities and advantages of electric truck business; (2) to interest central-station companies generally regarding the possibilities and advantages to them in cultivating an electric truck load, and (3) to provide for the industry practical advertising and sales helps and concrete suggestions for developing electric truck business.

#### Work to Be Done

The work of those in charge of this program is to cover the obtaining of data needed by the society in connection with the compilation of literature, editorial assistance in the preparation of articles to be released to the electrical trade press, the appointment of an advisory committee to aid participating organizations, preparing and maintaining a mailing list, gathering and distributing statistics, preparing for not less than 500 daily newspapers articles on the advantage of electric trucking, preparing articles both for popular magazines and for the electrical trade press, forming local committees, supplying selling suggestions and advertising copy, preparing material for lectures to the industry and to the public, arranging for the mention of electric trucks at meetings within the industry, preparing material for broadcasting by radio, preparing suitable printed matter for use within the industry and for distribution to consumers, and promoting classes for electric truck salesmen as detailed in the ELECTRICAL WORLD for May 5, page 1057.

Charles R. Skinner, Jr., manager of the automobile bureau of the New York Edison Company, has been made chairman of the advisory committee, of which other members are O. R. Hogue, chairman Commercial Section, N. E. L. A., and W. L. Goodwin, representing the Society for Electrical Development.

## Joint Committee for Business Development at Work

At a recent meeting of the executive committee of the Joint Committee for Business Develoment W. E. Clement, commercial agent of the New Orleans Public Service, Inc., was elected a member, thus giving representation to the South and Southwest and making a direct point of contact with the sectional joint committee which has been formed in the Southwestern Geographic Division of the National Electric Light Association, of which Mr. Clement is general chairman.

It was announced at the meeting that there are now 641 accepted correspondents of the joint committee in various parts of the country, and that there is a total of 1,341 with whom correspondence is being carried on with a view to having them serve. The hearty support of the committee was pledged to the "Better Homes in America" movement.

A co-operative program is being worked out with the American Bakers' Association which will assume definite proportions at an early date, and it was announced that satisfactory progress had been made in the adoption of a minimum iring standard. A report concerning this will probably be made within sixty days.

An extensive campaign dealing with the electric range was outlined by Oliver R. Hogue, chairman of the Commercial National Section, N. E. L. A. Charles R. Skinner, Jr., reported progress upon contemplated electric vehicle activity. A. K. Baylor reported that he was at work on a consumer booklet to be known as "Better Outlets for the Home." The booklet being prepared by the electric heating and melting department, Chairman C. K. Nichols reported, will soon be ready for final approval. C. E. Greenwood, chairman of the domestic and industrial appliances department, stated that the monograph his department had prepared on the vacuum cleaner had been completed and was ready for distribution. He announced that his department contemplated publishing a booklet on electric refrigeration at an early date. The chairman of the electric lighting department, P. B. Zimmerman, reported that a very complete monograph on domestic lighting had been issued and was ready for distribution.

A comprehensive program of booklets covering various fields was reported by William L. Goodwin of the Society for Electrical Development as ready. Louis D. Gibbs, chairman of the publicity advisory council, announced that the council is working to secure representation from all the associations affiliated with the joint committee.

## Conference Takes up Problems of Apparatus Users

A conference of men interested in the use or the manufacture of scientific instruments and apparatus was held recently at the headquarters of the National Research Council in Washington. It was attended by members of government scientific bureaus, scientific societies, universities, the Association of Scientific Apparatus Makers and individual firms. Dr. Burgess, director of the Bureau of Standards, presided. It was resolved that a committee of apparatus makers and users should be formed under the Research Extension Division of the council. This committee is to consist of one representative from each of eleven technical societies and organizations, including the American Institute of Electrical Engineers; two representatives from the Bureau of Standards and the National Research Council and six repr -entatives from the Association of Scientific Apparatus Manufacturers, with members-at-large to be appointed by this committee.

The principal discussions at the conference ranged around apparatus supply, standardization of apparatus, information service and inspection service.

## New Electrical Safety Rules for Indiana

The State Fire Marshal of Indiana, Newman T. Miller, has, in the interest of safety, promulgated the following rules for all new electrical installations or alterations:

1. Service entrance wires, from point of contact with the building up to and including the switch, meter connections and main cut-out fuses, must be completely inclosed within steel.

2. Continuous rigid metallic conduit must be used from point of contact with the building to and terminating within the service entrance switch and affixed rigidly thereto.

3. Service entrance switches must be of the externally operated safety inclosed type and provide means for sealing the inclosure containing the main cut-out switch and fuses.

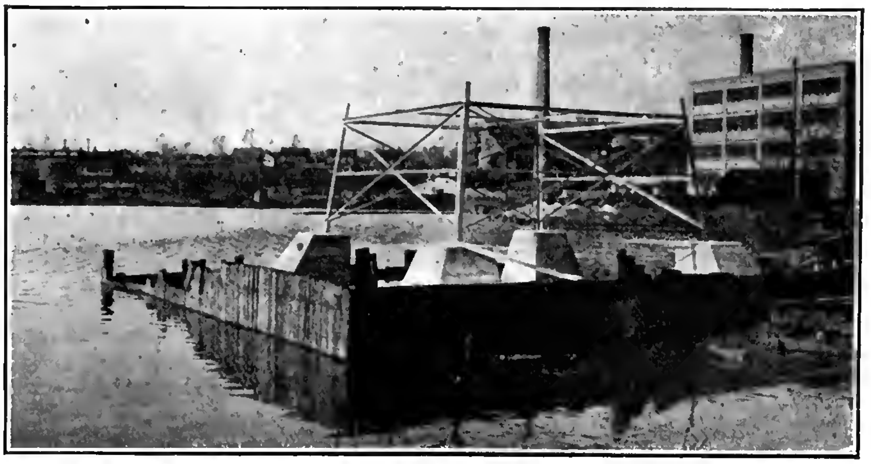
Switches must also provide means for entirely inclosing the meter connection wires within steel.

## Union Electric Light & Power Seeks to Expand

The Union Electric Light & Power Company of St. Louis has asked the Public Service Commission of Missouri for approval of its purchase of three properties which will give the company a string of electric utilities extending from St. Charles, Mo., on the north through southeastern Missouri to the northern boundary of Arkansas.

One group of properties which the company desires to purchase includes the St. Louis Light & Development Company, valued at $1,695,105; the Cape Girardeau & Jackson Interurban Railway, valued at $379,530; the St. Charles Electric Light & Power Company, valued at $106,591, and the Iron County Electric Light & Power Company, valued at $17,355. The second application asks permission to take over the Western Power & Light Company of St. Louis County, valued at $277,911, and the third application is for authority to purchase the lighting plants of the Missouri Public Utility Company at Bonne Terre, Cape Girardeau, Calfee, Charleston, East Prairie, Webb City, Sikeston and other smaller towns in southeastern Missouri.

## Building a Transmission Tower in a Lake



IN EXTENDING its new 110,000-volt line to Pittsfield, Mass., the Turners Falls Power Company was forced to build the abutments for one tower 50 ft. out from the shore of a small lake in the city limits, owing to the existence of a municipal ordinance making provision for a roadway along the shore of the lake to be built at some uncertain future date. It was at first planned to build a solid concrete pyramidal base, but so much difficulty was experienced in building and pumping out the necessary cofferdam that it became necessary to build individual piers for each leg of the tower. These are, however, tied together with arches of reinforced concrete. They extend 45 ft. down under water to bedrock. The work was done under trying winter conditions, and this one tower cost the power company nearly $35,000, or as much as forty similar towers constructed across open country.

## Brief News Notes

**Utica Rates Going Down.**—Officials of the Utica Gas & Electric Company have announced a reduction in rates for electricity used for lighting and power. The new schedule will represent a cut in cost to the consumer of about 10 per cent. The company says the new schedules will be operative by Oct. 1.

**San Diego Consolidated's Good Year.**—The San Diego Consolidated Gas & Electric Company reports that its electric operating revenue for the year 1922 was $2,169,025 and its electric operating expenses $1,541,470, giving a net operating electric revenue of $627,555. The company declared dividends of $528,843 during the year, leaving an accumulated surplus of $50,866.

**Eldora, Iowa, Is Connected with Transmission Line.** — A transmission line from the lines of the Iowa Falls Electric Company and the Iowa Railway & Light Company now furnishes service to Eldora, Iowa. The Iowa River Light & Power Company at Eldora has built this transmission line to Cleves and is receiving energy from the plants at Cedar Rapids, Iowa Falls and Marshalltown.

**Oxford, Ohio, Resolves to Keep Municipal Plant.** — Acquirement of new equipment for the municipal light and power plant at Oxford, Ohio, on a "lease-purchase" basis, was authorized by the City Council recently, after a proposal by the Ohio Gas & Electric Company to supply energy to the city on a wholesale basis on a ten-year contract had been rejected.

**Southern Indiana Gas & Electric Report.**—The Southern Indiana Gas & Electric Company of Evansville, which operates electric, gas, steam-heat, street-railway and interurban railway plants, had a combined net income for 1922 of $206,863, or $10,964.91 more than for 1921. The net income is the amount left after paying operating expenses, including taxes and depreciation, and after paying interest on debt. The company's surplus was $429,735.

**Municipal Ownership Wins in Red Wing, Minn.**—By large majorities the entire ticket favoring the construction of a municipal electric light and power plant has been elected in Red Wing, Minn., over the candidates advocating the purchase of energy from the Wisconsin-Minnesota Light & Power Company. The victory of municipal ownership comes after a bitter fight lasting over a period of many years.

**Southern Sierras Power Company's Report.**—The Southern Sierras Power Company, operating in Riverside, Hemet, San Bernadino and vicinity, reports to the California Railroad Commission for the year 1922 that its operating revenue was $2,010,744 and its operating expenses $814,075, giving a net operating revenue of $1,196,669. The net corporate income for the year was $79,053 and surplus $137,501.

**Oskaloosa Loses Permit.**—Failure to do the preliminary work required by the Federal Power Commission has resulted in the revocation of the preliminary permit granted the city of Oskaloosa, Iowa. The city had a plan for developing power on the Des Moines River.

**Geneva, Ill., Gives up Municipal Plant.**—The municipal generating plant of Geneva, Ill., has come to an end, and the city is henceforth to be served from the lines of the Chicago, Aurora & Elgin Railroad through its subsidiary, the Chicago Suburban Power & Light Company. The new rates will be lower than the cost of manufacture by the city, which will continue to distribute the electricity after transforming it from 30,000 volts to 2,300 volts.

**Study of California Rivers to Be Made.**—A study of the American River and of the proposed diversion of the Trinity into the Sacramento River is to be made by a board to be composed of a representative each of the War Department, of the Interior Department and of the Department of Agriculture. The study is to determine the best scheme of developing the power, irrigation, flood-control and navigation features of these rivers.

**Central Illinois Buys Athens Plant.**—The Central Illinois Public Service Company has purchased the Athens (Ill.) electric light plant and is now serving 195 communities with electric light and power. Business of the company is increasing rapidly. The average daily output of the Muddy power station has reached 220,000 kw.-hr., largely the result of the company's new contract with the Old Ben Coal Corporation, which it is serving with electrical energy for the operation of its coal mines.

**Lena (Ill.) Plant Serves Eighteen Communities.**—The Wisconsin Utilities Company of Monroe, Wis., a subsidiary of the United Utilities Company, Lena, Ill., announces the purchase of the plant and outside equipment of the Orangeville Electric Light & Power Company and its plan to supply that city with electricity. The Wisconsin Utilities Company has also signed an agreement with Clarno to furnish electricity there, making eighteen communities which will receive light and power from the Lena plant.

**California Oregon Power Company Busy.**—Three major construction jobs for the California Oregon Construction Company are under way. Work is progressing on the 20-mile extension of the 66,000-volt transmission system in Klamath County to the town of Chiloquin. This line will be completed in May. A suction dredge is being built to operate on Upper Klamath Lake in connection with the lake regulation project of the company. This will be ready for service this month. The transmission line from Fall Creek to Yreka, which was built in 1903, will be rebuilt and relocated.

**New Orleans Plant Must Have More Water.**—So much water has been used by the electric power plant of the New Orleans Public Service, Inc., at the foot of Market Street, since the installation of the new 20,000-kw. turbine-generator that it has been found necessary to augment the supply by building a new reinforced-concrete intake tunnel, 8 ft. x 10 ft., at a cost of about $500,000. Work will be started when the Mississippi River reaches a lower level. More water is consumed by the electric power plant than by the rest of the city combined, the power house requiring when operating at full capacity 11,570,000 gal. an hour.

**Missouri Pacific Abandons Steam Plant for Central-Station Service.**—The Missouri Pacific Railway Company has recently arranged to purchase electric service from the Union Electric Light & Power Company of St. Louis for the operation of all electric equipment at its shops in Dupo, Ill. The St. Louis company will deliver this service to the railroad company yards just south of St. Louis in the form of three-phase, 60-cycle, 13,200-volt energy, the Missouri Pacific Railway having installed a submarine cable across the Mississippi and constructed a 3-mile transmission line to Dupo and a 300-kva. substation. This contract means the abandonment of a steam plant which has been in operation at the Dupo shops for a number of years.

**San Francisco Holds Radio and Electrical Exposition.**—The National Radio and Electrical Exposition held in the Civic Auditorium, San Francisco, during the week of April 2 proved so successful that it has been decided to make it an annual event. It is estimated that twenty-five thousand persons visited the show during the six days it was in progress. The exposition was held primarily to demonstrate the progress that has been made in the art of radio communication, but electrical interests that had other displays capitalized on the public's interest in radio by showing the latest devices and appliances. Among the unique exhibits was a large illuminated map showing the power plants and the transmission system of the Pacific Gas & Electric Company.

**Government Engineers Continue Study of Snake River.**—The study of the power resources of Snake River begun in 1920 by an examination of the river between Huntington, Ore., and Lewiston, Idaho, by engineers of the United States Geological Survey was continued in 1921 by a similar examination of the river in southern Idaho, between Milner and Weiser, and manuscript copies of the report for that year are open for public inspection at the office of the Geological Survey in Washington and at the office of the district engineer at Boise. The report gives a history of the present development of power in southern Idaho and contains maps and descriptions of nineteen sites at which 250,000 hp. more could probably be developed even during times of low-water flow. It sets forth the amount of water available for power development and the schemes by which

the fullest use may be made of the water.

**Consummating Indiana Consolidation.**—The Wabash Valley Electric Company has petitioned the Indiana Public Service Commission for authority to buy the Putnam Electric Company, Cayuga Electric Company, Martinsville Gas & Electric Company, Spencer Light, Power & Water Company, Gosport Electric Company, Morgan County Light & Power Company and Roachdale Electric Company and to issue $1,561,700 of new securities to finance the deal. The petition says the properties are worth at least $2,073,000, against which there will be $1,811,700 in securities. The Central Indiana Power Company, which owns all the common stock of the Indiana Electric Corporation, owns the Wabash, Putnam and Cayuga companies, all of which were concerned in the hard-fought Indiana Electric Corporation case of 1921-1922. The whole system is to be provided with energy, in part at least, from the power plant which the Brewer interests are building near Terre Haute.

# Associations and Societies

**H. A. Lewis to Speak to New England Merchandising Bureau.**—H. A. Lewis of *Electrical Merchandising*, New York, is scheduled to address the Merchandising Bureau of the New England Division, N. E. L. A., upon "Compensation for Merchandising Salesmen," at the Congress Square Hotel, Portland, Me., at 1 p.m. Wednesday, May 16.

**American Welding Society's New President.**—In the ELECTRICAL WORLD'S report, on page 1053 last week, of the New York meeting of the American Welding Society it was erroneously stated that the president-elect, T. F. Barton, was "of the General Electric Company." Mr. Barton is master mechanic of the Delaware, Lackawanna & Western Railroad.

**Wenatchee Starts Electric Club.**—Power company representatives and electrical men of Wenatchee, Wash., met at an informal dinner recently for the purpose of organizing a local electric club. Ray U. Muffley, manager of the Washington Coast Utilities, was elected temporary chairman. The following officers were elected: President, Lewis Shreve; vice-president, V. R. Wright; secretary, W. A. Buttles; treasurer, H. L. Clark.

**Kansas Metermen Organize.**—At the close of the first annual meter school held by the department of electrical engineering of the Kansas State College at Manhattan, Kan., which was attended by fifty men, a permanent organization of Kansas metermen was effected. J. E. Brown of the Kansas Electric Power Company was elected president, and F. H. Pumphrey of Wichita and A. C. Krachy of Ellsworth committeemen.

**Power Development to Be a Topic at A. S. M. E. Convention.**—At the spring meeting of the American Society of Mechanical Engineers, to be held at Montreal on May 28-31, Julian C. Smith will discuss "Power Development in the Province of Quebec," Frederick A. Gaby "Development of Hydro-Electric Power Plants in Ontario," and H. G. Acres "Modern Hydraulic Turbines of Large Capacity."

**Empire State Gas and Electric Association.**—At the meeting of the electric section of this association on Thursday and Friday next week there will be reports from the following committee chairmen: Street lighting, K. V. Farmer, Syracuse; boiler-room operation, A. C. Jordon, Elmira; hydraulic power, H. G. Davis, Watertown; transmission lines, E. P. Peck, Utica; overhead distribution, H. W. Watt, Mount Vernon, and underground systems, R. A. Paine, Jr., Brooklyn.

**North Central, N. E. L. A., Convention Postponed.**—The convention of the North Central Geographic Division, N. E. L. A., originally scheduled to be held at the Curtis Hotel, Minneapolis, on June 13-15, will instead be held at the Radisson Hotel, in that city, on June 20-22. This postponement, the officers announce, has been necessitated by the mistake of the Curtis Hotel management in booking the convention for a week previously assigned by it to another gathering.

**May Section Meetings of A. I. E. E.**—Section meetings of the American Institute of Electrical Engineers still to be held this month are announced as follows: Baltimore, May 18, "Lighting of Factories and Office Buildings," Earl A. Anderson; Boston, May 15, annual entertainment; Cleveland, May 24, address by President Jewett; Erie, May 14, "Science of Musical Sounds," Dayton C. Miller; Philadelphia, May 14, C. J. Russell; Seattle, May 16, "Long-Distance Telephone Toll Cable;" Worcester, May 17, address by President Jewett.

**American Engineers Honor French Colleagues.**—A joint meeting of the four major engineering societies of America with the American Section of the Société des Ingénieurs Civils de France was held in New York on May 4, in honor of the seventy-fifth anniversary of the founding of the French society. Harrington Emerson, president of the American Section; Gaston Liebert, director of the French Bureau of Information; C. O. Mailloux, the president of the International Electrotechnical Commission; William Barclay Parsons, Arthur S. Dwight and Henri Vigneron spoke.

**Gerard Swope Addresses St. Louis Electrical Board.**—Gerard Swope, president of the General Electric Company, addressed the St. Louis Electrical Board of Trade on the subject of "The Future of the Electrical Industry" at its regular weekly luncheon at the Statler Hotel on May 1. Louis H. Egan, president of the Union Electric Light & Power Company, was chairman. Mr. Swope said that only about 30 per cent of the nation's industrial plants are operating with electric service. He also saw a great opportunity for steam railroad electrification, pointing to the strides that Italy has made along this line.

**Change of Meeting Place for Lighting Fixture Manufacturers.**—The place for holding the midsummer convention of the National Council Lighting Fixture Manufacturers has been changed from Hot Springs, Va., to Buffalo. The date, June 26-28, remains unchanged. On the first day there will be a design program under the direction of E. T. Caldwell, and the following questions will be taken up: (1) "Which is the more important, designing or merchandising?" (2) "Should the lighting-fixture industry follow period design as the furniture industry has done?" (3) "Are the designers asleep?" On the second day a publicity program will cover: (1) Value of a national publicity campaign to a trade association; (2) possible development of dealer contact in a publicity campaign; (3) merchandising possibilities for the individual manufacturer in an association publicity campaign. The last day will be given over to a business meeting.

## Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

Empire State Gas and Electric Association, Electric Section—Utica, N. Y., May 17-18. C. H. B. Chapin, Grand Central Terminal, New York.

Electrical Supply Jobbers' Association—Executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

Missouri Association of Public Utilities—River boat from St. Louis to Peoria, May 24-26.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

California State Association of Electrical Contractors and Dealers—Dorner Lake, Cal., June 9-16.

Electric Power Club — Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

North Central Division, N. E. L. A.—Minneapolis, June 20-22. H. E. Young, Minneapolis General Electric Company.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

Society for the Promotion of Engineering Education—Ithaca, N. Y., June 20-22. F. L. Bishop, University of Pittsburgh.

Canadian Electrical Association — Montreal, June 20-23. Louis Kon, 65 McGill College Ave., Montreal.

American Institute of Electrical Engineers—Annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

American Society for Testing Materials—Atlantic City, June 25-29.

Iowa Section, N. E. L. A. — Mason City, June 26-29.

Associated Manufacturers of Electrical Supplies—New London, Conn., June 26-29. Frederic Nicholas, 30 East 42d St., New York.

National Council Lighting Fixture Manufacturers—Buffalo, June 26-28. C. H. Hofrichter, 233 Gordon Square Bldg., Cleveland.

Northwest Electric Light and Power Association—Seattle, June 27-30. G. E. Quinan, 204 Electric Bldg., Seattle.

Ohio Electric Light Association — Cedar Point, July 10-13. D. L. Gaskill, Greenville.

New England Division, N. E. L. A.—Swampscott, Mass., Sept. 6-8. Miss O. A. Bursiel, 149 Tremont St., Boston.

Association of Iron and Steel Electrical Engineers—Buffalo, Sept. 24-28.

# Recent Court Decisions

**Where Evidence Is Equally Consistent with Existence or Non-Existence of Negligence Jury Is Not Competent.**—In a suit brought by one Martin against the Louisville Gas & Electric Company the plaintiff claimed damages for injuries caused by a fall from a ladder lawfully placed by defendant to take the place of cellar stairs temporarily removed to facilitate the laying of conduit. The evidence was held by the Court of Appeals of Kentucky to be equally consistent with the theory of the ladder having slipped or the plaintiff herself having done so, and therefore the trial judge was held to have done right in withdrawing the case from the jury and finding for the defendant, in the absence of testimony to establish its negligence. (248 S. W. 868.)*

**Federal Court Possesses No Jurisdiction in Suit to Enjoin Forfeiture of Franchise Rights by Judicial Process.**—In dissolving an injunction granted to the St. Johns (Fla.) Electric Company against the city of St. Augustine, the United States Circuit Court of Appeals held that where an electric light and railway company was informed by the city that if it failed to comply with a resolution requiring it to make certain repairs the city would take steps to forfeit its right to use the streets in connection with its electric light business, as well as its railway business, and where it is the city's intention to do this by judicial proceeding, a suit to enjoin such proceedings involves no question under the United States Constitution giving jurisdiction to a federal court, even though there is not sufficient ground for forfeiture. (286 Fed. 474.)

**Public Must Have Opportunity for Hearing Before Commission Fixes Rates.**—Asserting, in Jones vs. Montpelier & Barre Light & Power Company, that the authority of the Public Service Commission of Vermont to make orders affecting rates depends on due notice to the parties interested, the Vermont Supreme Court has declared that where a public service corporation filed with the commission schedules showing rates for electricity which were in force and also a schedule of rates to become effective later, and where this additional schedule was protested and ordered discontinued, and no appeal was taken or request for a rehearing made within the statutory period, the company's motion for rehearing in which it requested the commission to fix a rate effective as of the date petitioned for in place of the one requested can be treated only as a petition to pass on a schedule not previously filed with the commission or made known to the public. (120 At. 103.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

**Erroneous Instruction on Insulation of Broken Wire.**—A steam-shovel operator who broke a transmission wire with the boom of his shovel got down from the machine, picked up one end of the wire and was instantly killed. In reversing for the second time a judgment for damages (Hollis vs. Kansas City Light & Power Company) the Kansas City Court of Appeals found the instructions given to the jury to have been in error because they disregarded how or why the wire fell and stated a case of liability beginning with the wire on the ground and its state of insulation after it had fallen regardless of whether the action that caused it to fall was also the cause of the defective insulation. Although negligence and contributory negligence were questions for the jury, the petition was not based on the company's action in maintaining an electric wire close to a coal yard where it was likely to be broken regardless of its insulation, but on the alleged long-continued maintenance of the wire without sufficient insulation, and instructions to the jury should have been in accordance with this fact. The case was therefore remanded for a third trial. (248 S. W. 634.)

**Deduction of Depreciation Fund from Rate Base Held to Have Been Error.**—The action of the New York Public Service Commission in deducting a depreciation fund from the rate base of a natural-gas utility was held to be error in People ex rel. Pennsylvania Gas Company vs. Commission. The State Supreme Court said: "The commission seems to have determined that all sums of money collected from consumers for depletion of capital and carried to depreciation account, less such sums as might be traceable into free investments, whether used for replacement or enhancement of capital, constituted a fund which, whatever its converted form, could not be included in reckoning the capital constituting a proper rate base. That this cannot be true is shown by a simple illustration. Assume that the relator were presently embarking in the natural-gas business; that it owned ten wells each having its own acreage of gas fields; that each well with its fields was fairly worth $10,000; that consumers would so deplete its gas supply that in ten years the ten wells and fields would be exhausted. It is plain that in such case the consumers should annually pay, in addition to a suitable charge for service, the value of one gas well and field, or the sum of $10,000. If the consumers paid such a charge for ten years, then the relator might each year buy a new gas well with new field, or at the end of ten years buy itself ten new wells with gas fields, and thus place itself, not in a better, but in the exact position occupied by it when it began business. Clearly in such case the relator should be allowed a continuance of its charges for gas based on the full value of its capital without deductions. If sums annually collected from consumers for depletion of capital and actually used for such replacement must be deducted from capital invested to determine a rate base, then it is not apparent why such collections are ever permitted. If the commission intended merely to determine that sums of money collected for depletion which added to capital should be deducted, then the commission was likewise in error when it made the deduction in question. This is true for the reason that there is no proof that the sum was collected from consumers for depletion and used to increase capital rather than to replace it." (198 N. Y. S. 193.)

# Commission Rulings

**Power Company Not Compelled to Incur Large Expense to Avoid Possibility of Inductive Interference.**—In passing on an application from the Blue River Power Company for permission to construct a transmission line in certain territory, the Nebraska State Railway Commission refused to compel it to incur a substantial cost in order to avoid one mile of additional parallel with metallicized telephone circuits. The route that appeared to afford the fewest natural obstacles and parallels to telephone lines was selected, and the commission said that where the telephone circuits were metallicized, as all the important ones in this territory were, the inductive interference from power lines operating under normal conditions at ordinary voltages would not materially affect communication over the telephone wires.

**Michigan Commission on Financing of Utilities.**—In refusing to the Sault Ste. Marie Gas & Electric Company authorization for additional stock issues and modifying an order relating to refunding bonds, the Michigan Public Utilities Commission made these pronouncements: A deficit resulting from the failure of a public utility to earn a 7 per cent return upon the rate base is no foundation upon which to base the issuance of common capital stock; a public utility should not be permitted to issue stock based on reorganization expenditures made seven years ago and prior to commission regulation; a public utility company should not be permitted to issue stock based on rate-case expenditures not charged to operating expenses, since these expenditures are properly amortized over a period of years; a public utility cannot and should not sell any preferred stock for less than par under the laws of Michigan. No commission, it was further decreed, should be paid for the sale of preferred stock of a public utility company when it appears that one individual is the owner of virtually all of the capital securities and that the issue of stock, together with other matters affecting capitalization passed on by the commission, amounts to a reorganization of the corporation.

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## J. D. Andrew Vice-President of Stevens & Wood, Inc.

James D. Andrew has returned to the public utility engineering and construction fields by accepting the post of vice-president and district manager of Stevens & Wood, Inc., with offices at New York and Youngstown, Ohio. Mr. Andrew's headquarters will be at Youngstown, and one of his first activities will be charge of the construction of the 200,000-kw. superpower plant to be erected by his firm on the Ohio River. In returning to the public utility field, Mr. Andrew resigned as president of the American Balsa Company, a subsidiary of the American International Corporation, with which organization he became connected in war times, when, in 1917, he left his position as superintendent of station engineering for the Edison Illuminating Company of Boston to take a prominent part in the building of the great Hog Island plant.

Mr. Andrew was born in 1874 and was graduated from the Columbia School of Mines in 1897. He spent three years in erecting and testing engines for the E. P. Allis Company, Milwaukee, and the next three years as mechanical engineer of the Metropolitan Street Railway, New York. He then joined the New York Edison Company as chief engineer. Tempted by commercial activities, he next became general manager of the Virginia & Alberine Soapstone Company in charge of production and manufacture. The public utilities claimed him again when the Boston Elevated Railway made him superintendent of power, which position he relinquished to ally himself with the Edison Illuminating Company of Boston.

During 1916, however, he received leave of absence to go to South America for the Chili Copper Company to build and inaugurate a 40,000-kw. power plant.

**Frank L. Ostler** has been appointed secretary of the Public Utilities Commission of Utah, to succeed T. E. Banning, who resigned last February. Mr. Ostler has had considerable experience in rate work.

**R. E. Thompson** recently resigned as manager of the Deming (N. M.) Ice & Electric Company to become power superintendent for the Springfield (Mo.) Gas & Electric Company.

**H. S. Bastian**, assistant engineer of the Portland (Ore.) Railway, Light & Power Company, has resigned to take charge of the new district office of Charles C. Moore & Company. For a year before allying himself with the Portland Railway, Light & Power Company Mr. Bastian was engaged in private practice, chiefly mechanical and power-plant work. Previously he was associated with the Southern Pacific Company at San Francisco and also with the Oregon-Washington Railroad in Portland.

## W. H. Burke Goes to Iowa

Walter H. Burke, who has been transferred to Keokuk, Iowa, as manager of the railway, lighting, power and gas properties of the Keokuk Electric Company, as was announced in the April 21 issue of the ELECTRICAL WORLD, has been in the Boston office of Stone & Webster for some years and has in recent months been in charge of matters pertaining to the Southwestern group of properties under this management. Mr. Burke was graduated from the University of Maine in 1906. After serving for a time with the General Electric Company, he held various operating positions in the utility field, including that of assistant general superintendent of light and power for the Milwaukee Railway & Light Company and that of assistant to the manager of the railway, lighting and power property at Dallas, Tex. He has been a frequent contributor to the technical press, particularly on the economic phases of the public utility business. He assumed his new duties May 1.

W. H. BURKE

**M. C. Rypinski**, vice-president and general sales manager of C. Brandes, Inc., New York City, has started on a trip abroad. He will make his first stop in England, at the firm's London plant, to determine the advisability of its further expansion in order to keep up with the increasing demand for radio apparatus. He will then go to Paris and afterward into Germany. Mr. Rypinski will remain in Europe for a somewhat indefinite period.

**Rudolph P. Miller** of New York has been reappointed representative of the Federated American Engineering Societies on the National Board for Jurisdictional Awards.

**J. I. Searles**, who has been connected with the Menominee & Marinette Light & Traction Company since 1922, when he left the Wisconsin Railway, Light & Power Company at Winona, Minn., has severed his connection with the former company to ally himself with the Lake Superior District Power Company at Ironwood, Mich.

**Herbert L. Fisher** is now doing appraisal work with Stone & Webster, Boston. Mr. Fisher was formerly resident engineer with the Goodyear Tire & Rubber Company; then he joined the St. Croix Paper Company as assistant engineer of hydraulic construction, and later he was with the J. McCormick Construction Company, Philadelphia.

**William R. Bullard** has severed his connection with the United Electric Light & Power Company of New York, after seven years of service, to ally himself with the Electric Bond & Share Company, New York City, as assistant engineer in connection with the design and development of underground distribution systems.

**W. P. Strandborg** of the Portland (Ore.) Railway, Light & Power Company, president of the Public Utilities Section of the Associated Advertising Clubs of the World, has been appointed a member of the general reception committee to receive representative advertising and business men of the British Empire who will arrive in the United States the latter part of May for a tour of the Eastern and Middle Western sections of the country. The delegation will be composed of publishers, advertising specialists and representatives of large British industrial concerns. The party will attend the annual convention of the Associated Advertising Clubs of the World at Atlantic City early in June.

**William H. Crawford**, manager of the department of industries of the Portland (Ore.) Chamber of Commerce, has resigned to become affiliated with the California-Oregon Power Company. He has been appointed to organize a new service in the company, to be called the "new industries department," which will have for its purpose the encouragement of commercial development in the districts of southern Oregon and northern California served by the lines of the company. Before going to the Pacific Coast in 1902 Mr. Crawford spent two years in the Orient with Frazar & Company, importers, and several years on the Atlantic Coast selling railway appliances. Subsequently he was with Charles C. Moore & Company, engineers of San Francisco, for thirteen years, and he has also been associated with the Simmen Automatic Railway Signal Company of New York.

**H. W. Burmeister** has been made manager of the Flambeau Public Service Company's office at Phillips, Wis.

**R. H. McLain** recently resigned from the Maine Electric Company, Portland, Me., as sales manager and is now connected with the General Electric Company at its New York office.

**David Ross**, formerly connected with the Hydro-Electric Power Commission of Ontario, is now associated with the Electric Bond & Share Company, New York.

**John W. Carpenter**, vice-president and general manager of the Texas Power & Light Company of Dallas, has been made chairman of the public utilities committee of the Texas Chamber of Commerce.

**E. B. Powell**, consulting engineer, of Stone & Webster, Inc., Boston, has returned from France much improved in health. While abroad Mr. Powell was confined to the American Hospital at Neuilly for three months.

**W. F. Chadwick**, formerly assistant superintendent of gas and electric plants for the Connecticut Power Company, New London, Conn., has been transferred to the mechanical engineering division of Stone & Webster, Inc., at Boston.

**Fred Brown**, manager of the Mountain States Power Company in Eugene, Ore., for the last five years, has resigned. He has purchased an interest in the Buffelon Lumber Comnany and will have charge of the auditing and accounting for the firm.

**F. P. Nightingale**, who was formerly connected with the General Electric Company and who has just returned from a three years' stay in China in the interest of that company, is now connected with the Los Angeles office of the Pacific States Electric Company in the sales department.

**W. R. Marshall** has been made branch manager of the Buffalo sales office of the Westinghouse Electric & Manufacturing Company. Mr. Marshall has been a division manager connected with the New York office. C. W. Underwood, who was Buffalo branch manager, has been made Northern representative.

**Graeme Ross** has been appointed manager of the Kansas City branch office of the Westinghouse Electric & Manufacturing Company to succeed F. F. Rossman, who has resigned to accept the position of vice-president of the Mobile (Ala.) Light & Railway Company.

**Allen B. Coffman** has resigned as sales engineer for the Crouse-Hinds Company to become manager of the Philadelphia district of the Reliance Electric & Engineering Company, Cleveland, manufacturer of electric motors. In the past three years, while connected with the Crouse-Hinds Company, Mr. Coffman has made a study of different types of electrical installations in various industries from Pennsylvania to Florida. He will continue to make his headquarters in Philadelphia.

## C. J. Snyder Goes to Duluth

Carl J. Snyder has resigned as chief engineer of the Nebraska Power Company at Omaha to become manager of the commercial service department of the Duluth Edison Electric Company. Mr. Snyder was graduated in electrical engineering from the Iowa State College at Ames in 1909 and has been associated with the Nebraska Power Company in construction, operation and engineering work since that date. Under his direction the duties of the engineering department have been expanded to include phases of utility operation not usually handled by that department. This work includes the issuing of all plans, estimates and orders for all construction resulting from customers' applications for service and also all property accounting records. Mr. Snyder has taken an active part in the work of several of the technical committees of the National Electric Light Association and at present is vice-chairman of the Middle West Division Technical Section.

C. J. Snyder

**E. S. Fitz**, formerly general superintendent of the Houghton County Electric Light Company, Houghton, Mich., is now engineer in the power-station betterment division of Stone & Webster, Inc., Boston.

**Otto E. Huebner**, who had been associated with the New York & Queens Electric Light & Power Company for three and a half years, has resigned to manage the Exide Battery Service station in Flushing, L. I.

**A. L. Schieher**, formerly manager of the generator section of the power department of the Westinghouse Electric & Manufacturing Company, has been appointed to the recently created position of export representative of that department. Mr. Schieber is well fitted for the position, since in connection with his former duties he had considerable contact with foreign work. He will be succeeded as manager of the generator section by Willard Lofton, who for some time has been in active charge of the work of that section under Mr. Schieber's direction.

**O. H. Eschholz**, design and development engineer for the Westinghouse Electric & Manufacturing Company since 1910, has been appointed general manager of the Pittsburgh Chemical Company. Of late years Mr. Eschholz has devoted much time to research and the investigation of vapor arcs, electron emission, rectification, arc welding, precipitation, arc-rupture phenomena and breaker construction. He has also to his credit special achievement in the development of direct-current interpole generators, welding apparatus and processes and electrostatic precipitation apparatus and processes and has contributed widely to the electrical press.

**E. A. Hawkins**, vice-president and general manager of the Webster Electric Company, Racine, Wis., since 1919, has resigned his position and on May 1 assumed the duties of manager of the telephone and appliance departments in the general sales department of the Western Electric Company at its headquarters in New York City. Mr. Hawkins was with the Western Electric Company for nineteen years before going to Racine. He will direct the manufacture and sale of appliances manufactured by other concerns for the Western Electric Company and before going to New York will visit a number of factories in the Middle West which are under contract with the Western Electric Company. His successor at Racine has not been named.

# Obituary

**John Gilbert Ward**, treasurer of the Babcock & Wilcox Company, died in New York City on Sunday, April 22.

**Randolph Troy**, manager of transformer specialty sales of the merchandise department of the General Electric Company, died of pneumonia in the House of Mercy Hospital, Pittsfield, Mass., April 26, after an illness of three days. Mr. Troy had been associated with the General Electric Company since 1906, and when the merchandise department was organized last year he was assigned to the position he occupied at the time of his death.

**Donald Strode Barton**, formerly general manager of the Canadian Electric Light Company, Levis, and consulting engineer of the Quebec Railway, Light, Heat & Power Company, is dead. Mr. Barton was born in India and was educated in England. He went to Canada in 1900. He settled in Montreal and practiced his profession there for five years, when he accepted an appointment as general manager of the Canadian Electric Light Company and at the same time became consulting engineer of the Quebec Railway. When the Levis company was absorbed by the Quebec Railway he remained with the company in the capacity of consulting engineer.

# Manufacturing and Markets

Devoted to the Discussion of Business and Economic Problems of the Producer and Distributor, with Market Reports, Trade Activities, Foreign and Construction News

## Metric System in Electrical Industry

**Although Manufacturers Would Share Inconvenience of Change, They Would Share Also in Benefits—Present Conflict with Other Countries Over Measurements**

By Burt L. Newkirk

Research Laboratory, General Electric Company, Schenectady, N. Y.

The electrical industry now uses metric units for electrical quantities, but the dimensions of the motors, generators, turbines and other apparatus necessary to the production, control or utilization of electrical energy are designed and manufactured to inch and foot dimensions. The metric system of weights and measures is the fundamental standard in the United States. The law of 1866 legalized the use of the metric units and established a table of equivalents between metric and American measures of length, capacity, area and weight. In 1893 "the Superintendent of Weights and Measures, with the approval of the Secretary of the Treasury, decided that the international meter and kilogram would in the future be regarded as the fundamental standards of length and mass in the United States, both for metric and customary weights and measures." When the Bureau of Standards was established in July, 1901, this decision, made in 1893 by the Bureau of Weights and Measures, was accepted. Thus by law and by action of the Government bureaus the metric weights and measures have legal standing and authority as the fundamental units.

### Background of Metric System

These standards are made with great care, of materials that, to the best of our knowledge, will not change. They are so fortified by the existence of other copies of the international meter and kilogram, distributed throughout the world, that irreparable loss of the standards is not to be feared. The International Bureau of Weights and Measures is maintained by seventeen countries for the care and preservation of these standards and the periodic intercomparison of the same. I think no informed person would claim that any other standards compare with those of the metric system in satisfying the requirements of a fundamental standard.

The metric system was devised and adopted in France during the French Revolution, when radical reforms were the order of the day. It was adopted in Germany at the time of achievement of national unity and in Italy under similar circumstances. The countries of South America adopted the metric system in the early stages of their national development. Japan has recently taken similar action, and it is reported that Russia and the new nations which were formerly part of Russia have done likewise.

In the United States the avoirdupois pound and the inch are pretty well intrenched in industry and in the life of the people. These are defined by federal law and so are standard throughout the land. There is also practical agreement with the British Empire on these units. The measures of capacity—that is, gallons—are not identical, the British Imperial gallon being 20 per cent larger than the United States gallon of 231 cu.in. Much pressure is being brought to bear on both sides of the water in favor of a change to the metric system, but so far without entire success. The reasons are not far to seek. The chaos in the old standards that impelled the French, Germans and Italians to change does not exist here or in Britain, and our pound, foot and gallon are deeply rooted in our industrial and civil life.

### Alarm Is Unjustified

The alarm with which some manufacturers view the prospect of changing to the metric system seems unjustified. A few firms in this country are now doing their manufacturing essentially on a metric basis. Many firms are serving their export trade with goods made to metric dimensions. There is probably some embarrassment in getting stock, tools, etc., to metric dimensions, but if this entailed much loss of money it is not likely that these firms would continue their allegiance to the system.

The change can be made in the drafting room without delay or serious inconvenience. The fundamental gages are re-etched, but the product is not changed in any dimension; consequently the production gages are not changed. New designs are laid out to metric dimensions and the draftsmen, tool makers and shop foreman must know how to read blueprints and to measure lengths in millimeters, but even this is not required of the operator of a production machine. Either metric or American drills, taps, dies, etc., may be used. Gages become obsolete and tools wear out and these can be replaced to keep pace with any gradual process of change to a new system. That any considerable proportion of the machine tools now in operation in this country would be scrapped in changing to a metric basis does not seem to me to be at all probable.

### Ultimate Yield to System

If our manufacturers were persuaded of the desirability of changing, they would do it easily and without serious loss to themselves. In fact, many of them are now manufacturing to metric dimensions for the export trade, and no one has claimed, I think, that these metric goods cost much, if any, more to produce than the standard product. Various circumstances other than the demands of export trade are working to introduce the metric system into American industry. Among these may be mentioned the influence of science upon industry, the operation of international affiliations and the prospect of world standardization in particular manufacturing specialties.

In spite of the intrenchment of the

inch, pound and gallon in industry and in the common life of a very aggressive race, they must ultimately yield to the metric system. The latter is universally accepted and used in science; the electrical units are metric; new industries, as, for example, the manufacture of ball bearings, are building up on the metric basis, and apparently an overwhelming majority of the world's population is getting into line on the metric side. In Great Britain and the United States merchants, boards of trade, statesmen, educators and business men appreciate the advantages of the metric system and favor its adoption. The opposition centers about the difficulty of changing such fundamental things as screw-thread spacings and other dimensions that have become standard. In my opinion, however, the adoption of the metric system does not involve necessarily changing screw-thread spacings or shapes, wire gages, sheet-metal gages, etc.

We should undoubtedly continue to designate nails as sixpenny, tenpenny, etc., because at one time some nails sold six for a penny and others ten for a penny. In a similar way a metric world may accept our Brown & Sharpe wire gage or our United States standard screw threads, or it may choose to standardize wire sizes and screw threads devised on a basis of metric dimensions. But metricists, in my opinion, are under no obligation to convince the public that these things, deeply rooted in American industry, ought to be changed as part of a metric program. Their burden is to show that the metric system should be made the dominant one and to outline a program adequate to accomplish this with the minimum inconvenience and expense to the country. The extent to which present manufacturing practice should be modified to adjust itself most economically to the metric basis would then be worked out in detail with much care and study of each step, but future developments would build up naturally on the new basis. New industrial projects would reap the advantage of an interrelated set of units common throughout the world.

# The Insecurity of "High-Price" Business*

**Country's Progress Stops When Business Is Gained Too Easily—High Prices at Home Create Indifference Toward Exports**

By Edward N. Hurley
Chairman of the Board,
Hurley Washing Machine Company

What incentive or necessity do men have to decrease costs and increase their efficiency if their margin of profits is abnormally high? There is danger in war profits, danger in after-war profits, danger in the feeling that there is no competitor in the world worth fearing. Men say, "What is the use of trying to increase our profits by economy when we can get the prices we ask?"

The pioneers in American industry won their success by fighting hard for business. It was a sporting proposition and the best man won in obtaining the order. If, by a combination of circumstances, this American fighting spirit is to be allayed and we obtain business easily and at high prices, it is only a question of time before business executives become inefficient, and inefficient management produces inefficient workmen. This would seriously affect the progress of our country.

### Danger in Overconfidence

Sometimes I think we are too cocksure of our efficiency and think we know it all. Most of us have really been lucky instead of efficient, and we must not think that large profits are always an indication of efficiency.

Germany had the feeling in 1914 that she was 100 per cent efficient in all things, but the many lessons she learned during and since the war may be a great blessing to her future economic development. Our country, swinging into a constantly developing period of improvement in most of our principal industries, and with some very sharp lessons of our own gained during the post-war period, most certainly should not let slip her golden opportunity to build an enduring and all-inclusive prosperity.

Foreign trade also requires some of the old American clipper-ship fighting spirit, and the exporters and their salesmen who are blazing the trail, selling American goods in the markets of the world, should be on our country's roll of honor, particularly when they not only have the difficulty of obtaining business for export, but in addition have the hard task of keeping American manufacturers sufficiently interested to fill export orders.

### Lesson of Price Boycott

American orders at home are being obtained without very much effort and in many cases at high prices. These high prices on domestic orders frequently create indifference toward foreign trade, seriously affecting our merchant marine and our country at a period when we need exports to balance our increasing imports.

The American housewives bought and hoarded sugar in 1919, resulting in a great scarcity and causing abnormally high prices. Manufacturers and merchants did the same in 1920 in hoarding materials, thus creating a shortage and causing untold losses of millions to them and to the country. This lesson must not be forgotten, and the fact that prices are higher should not encourage us to borrow money to again selfishly hoard surplus materials.

I believe in the ability and the integrity of the American business man, but I do not think he is putting forth that effort to reduce the cost of manufacturing and selling his wares that he is capable of doing. What might be termed post-war necessity is now ignored by most of us. The war produced high prices and abnormal profits from the effect of which we have not recovered.

### Cost Reduction Vital

A reduction in costs of manufacturing and the employment of every inch of floor space in every factory were never so much needed. Some concerns, through a combination of circumstances, have been able to make profits without doing this. They must, however, soon fall into line. Industrial building should be kept at a minimum. Let the employees do the building, so that they may have their own homes—another feature of real prosperity.

War and war profits retarded the progress and natural development of our country. There must be a readjustment. While many of us urge

*An address given before the second general session of the Tenth National Foreign Trade Convention, New Orleans, May 3, 1923.

the readjustment of labor as a remedy, management must also be readjusted to meet new conditions. Labor can become more efficient—so can management. Unless we improve our methods so as to increase our profits by lowering our costs of manufacturing and selling and adding to our list of customers foreign purchasers, we are not working on a sound basis. Now is emphatically the time to avoid the errors of 1920, to keep a sane attitude toward industry, to be satisfied with a production schedule that fairly meets the demand but falls short of overproduction—and to increase profits not by increasing prices, but by reducing costs of the business we are already enjoying.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

## Chicago Business Generally Is Very Active

THE electrical trade again reports very good business for the past week. Several advances in price were also announced. Motors have advanced approximately 4 to 6 per cent. One company changed some of its slip-ring types from a 50-deg. to a 40-deg. rating. Control apparatus advanced ten per cent and a general revision of list prices was announced. In some cases these lists were reduced or equalized, while in others they were advanced. The same was true of motors. Western red-cedar poles advanced 10 to 18 per cent, while the condition of stocks has not changed at this time.

Building permits exceeded those issued last year by about thirty permits, while the amount of money involved exceeded that of last year by approximately a million dollars. Conduit stocks are still low.

## Prices of Lamps Are Now Below Pre-War Level

IN VIEW of the fact that incandescent lamps are the most frequent points of contact electrical stores have with their customers, and, particularly, since every user of electricity is a buyer of lamps, it is interesting to review here the trend of prices of incandescent lamps during the past few years.

Because of improvements in manufacturing methods, in spite of the rising costs of material and labor, increases in lamp prices during the wartime period were small compared with those that took place with other commodities. In the face of generally increasing prices in commodities at the present time, it is interesting to note that these recent changes bring the prices of lamps below the pre-war level on both vacuum and gas-filled types, and in the case of the gas-filled lamp these prices are the lowest in the history of the industry.

The reduction just made is the third since April 1, 1922, when there was a readjustment in which "Mazda C" lamps were reduced about 5 per cent and "Mazda B" lamps on an average 12½ per cent. On Oct. 1, 1922, a reduction was made in the prices of "Mazda C" lamps which averaged about 20 per cent.

| Size of Lamp (Watts) | Jan. 1, 1922 | April 1, 1922 | Oct. 1, 1922 | May 1, 1923 |
|---|---|---|---|---|
| | | "Mazda B" | | |
| 10-50 | $0.40 | $0 35 | $0 35 | $0.32 |
| 60 | 0.45 | 0.40 | 0 40 | 0 37 |
| | | "Mazda C" | | |
| 50 | .60 | 55 | 55 | .50 |
| 75 | .70 | .70 | .60 | .55 |
| 100 | 1.00 | .95 | .75 | .70 |
| 150 | 1.40 | 1 30 | 1 00 | 90 |
| 200 | 1.90 | 1 80 | 1 30 | 1.15 |
| 300 | 2.80 | 2.50 | 1.90 | 1.75 |
| 500 | 4 15 | 3.75 | 2 75 | 2 50 |

| 1,000 | 6.70 | 6.00 | 4 50 | 4 25 |

The accompanying table shows Mazda lamp prices at important points during the last few years.

## Business in New England Continues at Full Tide

BUSINESS continues at full tide, the pressure for wage inflation being the most active disturbing factor for the time being. The expansion of central-station plants continues to astonish investors, and the demand for service is reflected in the success of widespread house-wiring campaigns and increasing purchases of electrical material by industrial and mercantile establishments. Last week's falling prices of securities and the weakening tendency of some raw materials has caused slowing down of commitments to far-reaching projects, but on the whole the New England States are sharing in the great production volume common to other sections of the country.

Retail business is improving with better weather, but in northern New England trade has been much upset temporarily by floods now fast subsiding. An epochal announcement in generating-plant plans was made at Boston last week in connection with the proposed use of 1,200 lb. steam pressure at the Weymouth station of the Edison Electric Illuminating Company, and it is noteworthy that this same pressure is being considered for some other contemplated plant construction in Massachusetts.

The effect of such announcements upon the sale of plant engineering equipment is not easily measured as regards future marketing of boilers and accessory machinery, but this and new high-tension line and switch-house construction proposed or under way in Massachusetts have a trade reaction of considerable interest.

Building contracts in New England for the week ended May 1 were the largest for this week in twenty-three years, a total of $8,942,900. Jobbers of electrical material report some improvement in transportation conditions and also some shortening of deliveries. Lamp prices were reduced from list about 8 per cent last week, and cotton, copper, rubber, steel and lead display weakness on current quotations. Stocks of Boston jobbers were well-rounded Monday, buying being well sustained.

## Appliance Sales Respond to Improved Merchandising Methods

REPORTS of appliance sales from week to week indicate increasing interest on the part of the public in labor-saving devices for the home, the larger equipment being in unusually active demand. In some quarters sales of washers, cleaners and refrigerating apparatus during the last few weeks have picked up rapidly. One Eastern central-station company sold 100 washers during April, and in the same territory the demand for cleaners revived to a gross well above the preceding month.

Portable lamps are moving faster than is normal for this season. Stocks of fans are being laid in against the anticipated early summer demand. Popular appreciation of moderate-priced devices like waffle irons, toasters and small disk heaters is encouraging, and one central-station exhausted its stock of the former soon after the beginning of a special campaign which offered nine-dollar units on the basis of $1 down and easy time payments. The relation between appliance sales

## Comparative Priees of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | $0.034 | $0.0322 | $0.0236 |
| Cold finished shafting, per lb. | 0.042 | 0.0406 | 0.032 |
| Brass rods, per lb. | 0.1913 | 0.1913 | 0.15 |
| Solder (half and half), per lb. | 0.2987 | 0.314 | 0.21 |
| Cotton waste, per lb. | 0.1231 | 0.1231 | 0.104 |
| Washers, cast iron (½-in.), per 100 lb. | 4.66 | 4.50 | 4.00 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 2.96 | 3.11 |
| Machine oil, per gal. | 0.349 | 0.349 | 0.40 |
| Belting, leather, medium, off list | 42% | 42% | 48¾% |
| Machine bolts, up to 1-in. x 30-in., off list | 44¼% | 48¾% | 62½% |

and prices is interesting managers of retail departments keenly at this time. The opinion was expressed to a representative of the ELECTRICAL WORLD recently that if manufacturers of appliances can build business on the basis of increased sales volume and a moderate profit per unit marketed, the public will "stay with" the industry as a continuous and expanding purchaser.

The point was made that appliance prices have in many cases been reduced materially during the past two or three years; that the public has responded to these reductions, and that the utmost effort to develop quantity business and to absorb cost increases if possible in expanding gross sales will prove the best policy. Some significance attaches to the fact that the upward pressure of costs has thus far been widely resisted by manufacturers. The outlook continues excellent for appliance sales throughout an immense range of types, designs and prices.

## Better Advertising Must Be Used to Get Foreign Trade

IN A COMPREHENSIVE survey of advertising for the electrical export field, G. Grenville Hunter of the International General Electric Company, Inc., told the tenth national foreign trade convention at New Orleans that there is no specter to intimidate or deter American traders from securing their share of profits from overseas markets, provided the right kind of publicity is used.

"You must remember," said Mr. Hunter, "that in foreign advertising you must take dealer representation as you find it—some of it good, most of it bad. You must direct your advertising toward making these dealers better merchants of your particular product through the medium of your advertising, which plays a definite part in making people want what your dealers sell; then selling them what they want in a way that will make them want more. Any advertising material which you send out will be of little value unless it is made of value by the dealers who use it. It will be of greatest value when these dealers are taught how to use it, and this is the first fundamental step in moving your goods from the dealer's shelf into the customer's hands.

"'Americanism' must be avoided at all costs because, while it is true that merchandising development in the United States has reached a stage in advance of many countries, nevertheless in using our experience as a cri-

terion we must be exceedingly careful to show ourselves friends rather than shining examples of Yankee efficiency."

Referring to the participation of American shippers in fairs and exhibits abroad, Mr. Hunter stressed the importance of sending the right type of representative. Much damage has been done—and is still being done—to our foreign trade by the "fresh" type of Yankee salesman, with whom the foreigner will have nothing to do.

## The Ruhr Occupation and the Electric Industry

OCCUPATION of the Ruhr has not as yet made itself felt in the German electrotechnical industry, says Dr. Carl Friedrich von Siemens, chairman of the board of the Siemens & Halske Aktien-Gesellschaft, in his annual report under date of March 22. Extracts from the report, translated by the Department of Commerce, are as follows:

"No reduction in unproductive expenses was possible. Instead there was an increase. Prospects of improvement are poor at this time. Drafts of new laws and regulations promise to place further obstacles in the path of orderly economic development. One soon will be able to speak of Germany as a wonderfully well-organized country theoretically but one in which practical life is extremely difficult.

"New orders are decreasing considerably, largely because of the appreciation of the mark and the hope of further price reductions. This is the counter-movement in speculation. Reduction of prices for electrotechnical products is not prevented by a desire to sell at prices which will cover the costs of materials purchased at higher prices than those which obtain today, but is made impossible by the prevailing high costs of material, by high wages and by greatly increased overhead expense. If we do not succeed in bringing down these expenses to their former level and in increasing production, and, further, if we are unable to pay satisfactory returns upon invested capital and to bring down prices to the world level at least, it will be impossible longer to maintain German industry."

## The Metal Market

Demand for copper during the past week has been very slow. Sellers and consumers seemed to be sparring and waiting for developments during the greater part of the period, but in the

NEW YORK METAL MARKET PRICES

| | May 2, 1923 Cents per Pound | May 9, 1923 Cents per Pound |
|---|---|---|
| Copper, electrolytic | 16.75 to 17.00 | 11.50 to 16.62½ |
| Lead, Am. S. & R. price | 8.00 | 8.00 |
| Antimony | 8.00 to 8.25 | 8.00 to 8.25 |
| Nickel, ingot | 28.00–30.00 | 28.00 to 30.00 |
| Zinc, spot | 7.37½ | 7.37½ |
| Tin, Straits | 45.00 | 45.00 |
| Aluminum, 98 to 99 per cent | 26.00 | 26.00 |

end it was stated that inquiries were slightly better.

Reports were circulated that one of the first hands had been offering copper at 16.37½ cents per pound, but this was emphatically denied in well-informed trade quarters, and an investigation among the sellers does not confirm the rumor. As a matter of fact, the big interests held for 16.62½ cents per pound, which appeared to be the low point on copper delivered at the plants of the consumer.

One or two sales actually were made at 16.50 cents per pound, but these transactions were exceptional, because they did not involve any delivery charges to speak of and were practically f.o.b. New York, or the equivalent of at least 16.62½ cents per pound delivered at the consuming point on ordinary transactions.

Second hands and those handling resales of the metal continued to shade prices and give concessions under the quotations of the big interests, but this is to be expected in a market such as has been experienced in the past few weeks. It is possible that one of these offered the metal at 16.37½ cents during the week, but even this could not be confirmed.

That there is a big demand for copper to come into the market is the popular opinion among the best posted authorities. Few of the sellers have been willing to dispose of the metal beyond July delivery, and as a result of that attitude the consumers have but small supplies of the metal on hand for their future needs.

# Activities of the Trade

Devoted to News of the Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Plainville to Assemble Trumbull-Vanderpoel Inclosed Switch Parts

The growth of the inclosed-switch business of the Trumbull-Vanderpoel Company, Bantam, Conn., has led to an agreement with the Plainville (Conn.) Electrical Products Company whereby the latter will assemble and market this portion of the Bantam company's output. The Trumbull-Vanderpoel Company will continue to manufacture inclosed knife switches, safety switches, meter switches and the Mason safety switch for line service.

## Twenty-two Makers and Agents at New York Cleaner Show

Twenty - two manufacturers and agents of vacuum cleaners have accepted the New York Edison Company's invitation to exhibit standard makes and different types in the Irving Place showroom May 14 to 19. Electric scrubbing and polishing machines will be shown.

## Calorizing Company Formed by General Electric Interests

The Calorizing Company has been incorporated under the laws of Delaware to take over the assets and business of the Calorizing Company of Pittsburgh, which has developed commercially a heat-treating process originated by the General Electric Company, by which aluminum is driven into the surface of metals, thereby greatly increasing their resistance to high temperatures and to certain corrosive reactions. The new company, with headquarters in Pittsburgh, has an authorized capital of 30,000 shares of 8 per cent cumulative convertible stock at $25 par value and 100,000 shares of common stock at no par value. The General Electric Company owns 25 per cent of the common stock.

## Walker Electric Vehicle Opens Atlanta Branch Office

The Walker Vehicle Company, Chicago, manufacturer of Walker balance-drive electric trucks for city routes, has opened a branch office in Atlanta. P. C. Pomeroy, who has had extensive experience in trucking matters while representing the White and Packard organizations, has been appointed district manager, with offices at 926 Hurt Building, Atlanta.

## Brisk Fan Business for the Emerson Electric Company

The Emerson Electric Company, St. Louis, reports large orders for fans from the South and Southwest. Building activities in Texas are responsible for a number of very large orders for future delivery. There is every indication that this will be a banner fan season, notwithstanding the fact that it has been a rather cool spring. Jobbers and retail dealers in all parts of the country have had their stocks depleted and are ordering for immediate delivery. It is interesting to note the unusual number of orders that have recently been received for 32-volt fans for use with farm-lighting outfits, which is a natural reflection of the present activity in farm-lighting plants.

## Denver and Butte Jobbers Hold Joint Sales Convention

The Capital Electric Company, Salt Lake City, Western distributor of General Electric products, and the Butte Electric Supply Company of Butte, Mont., held a joint sales convention on May 3 and 4. H. D. Randall of the General Electric Company delivered a lecture on the outlook for the rest of 1923.

Forty salesmen attended the convention. Encouraging reports were brought from various points of the intermountain territory. J. A. Kahn, president of the Capital Electric Company, was in charge of the convention.

## Westinghouse Receives $1,000,000 Order from West Penn Power

The West Penn Power Company has placed with the Westinghouse Electric & Manufacturing Company an order amounting to more than $1,000,000. The contract includes seven 12,000-kva., three 10,000-kva., ten 6,000-kva., three 2,000-kva. and three 1,000-kva transformers for 60-cycle, single-phase service; one 5,000-kva., 4,000-volt synchronous condenser for three-phase, 60-cycle operation; 133 oil circuit breakers and seventeen lightning arresters. Most of this apparatus duplicates existing equipment and is to be used for making extensions in the system of the company.

## Johns-Pratt Company Establishes Export Division in New York

The Johns-Pratt Company, Hartford, Conn., manufacturer of "Noark" fuses, meter-service and protective devices, has established an export division with office at 30 Church Street, New York City. E. Wilhelm Droosten and W. L. Urquhart, who have had extensive experience in handling export business of electrical manufacturers, will be in charge of this division.

The company also announces that arrangements have recently been made with the Curtin Mill Supply Company, Houston; Globe Supply & Machinery Company, New Orleans; Hide, Leather & Belting Company, Indianapolis; Hardy & Dischinger, Toledo; Rathbun Company, El Paso; Miller Supply Company, Huntington; Walworth-Ohio Company, Cleveland, and the Wayne Belting & Supply Company, Fort Wayne, as distributors for its power-plant specialties.

## Starbuck Sprague Forms New Supply Jobbing House

A new electrical supply jobbing house has been organized at Waterbury, Conn., under the name of the Sprague Electrical Supply Company, quarters having been secured at 39 Spring Street, in the heart of the wholesale district. The company is a Connecticut corporation with an authorized capital of $112,500, and the officers are: President, Starbuck

Sprague; secretary, Weston M. Jenks; treasurer, R. G. Stewart; sales manager, Harry A. Squires.

The company has leased a three-story building with more than 4,000 sq.ft. on the main floor and over 2,000 sq.ft. on each of the two upper floors. The organization is launched to do a wholesale business without retail or contracting connections, and it will open with three men on the road, covering the Naugatuck Valley of Connecticut from Winsted to Ansonia and Derby, and from Danbury on the west to Southington and Cheshire on the east.

The company has been appointed distributor for Bryant, Johns-Pratt, Tubular Woven Fabric, Bryant-Marsh, Trumbull-Vanderpoel, Central Tube, Steel City, Federal Armored Cable and other products.

Mr. Sprague is widely known in New England electrical circles. He was graduated from Harvard College in 1907 and after two years in the electrical construction field spent seven years in the supply department of the General Electric Company and seven years as director and sales manager for the New England Engineering Company of Waterbury. Mr. Squires was graduated from Pratt Institute, Brooklyn, in 1916, and after two years with the Public Service Company of Northern Illinois spent five years with the New England Engineering Company.

## Northwestern Electric Equipment Now Is Distributor Only

The Northwestern Electric Equipment Company, 174 East Sixth Street, St. Paul, Minn., will in the future confine its commercial efforts to the wholesale distribution of electrical, radio and telephone supplies, appliances and apparatus, including motors, switchboards, panels and cabinets.

J. M. Whalen and A. S. Abbott, with other former employees of the Northwestern firm, have purchased the company's interest in the Commonwealth Electric Company, the company's former manufacturing and repair departments, and will operate under the name of the Commonwealth Electric Company at 417 Broadway, St. Paul.

The retail department of the former Commonwealth Electric Company has been sold to E. S. Talmadge and C. J. Otterholm, who will continue that business under the name of the Commonwealth Appliance Company at 373 Robert Street.

## Tungsten Light Manufacturer Buys Springfield Plant

The M. & W. Company, manufacturers of tungsten electric light bulbs, has bought a factory building from the Knox Motors Company, in Springfield, Mass., to which it will remove soon from its Taylor Street location. In place of paying four different rents in its present quarters, the concern will have a larger but more compact establishment comprising about 80,000 sq.ft. on four floors, enabling it to organize its business to good advantage and also expand to meet increased demands.

The new location is directly alongside the tracks of the New York, New Haven & Hartford's Highland division. The M. & W. Company is a licensee of the General Electric Company, and its production quota has of late been increased in a decided degree. C. F. Munder is president and treasurer of the company.

## Electric Storage Battery to Sell Stock to Employees

The Electric Storage Battery Company, Philadelphia, announces that it has recently made arrangements by which employees may purchase shares of common stock. The plan enables employees to become stockholders under advantageous terms, keeping the payments down to easy monthly installments.

Under the plan, if the present rate of dividends—viz., $1 per share per quarter—continues, stock subscribed for at $53 per share will be fully paid for after forty months—that is, $40 per share will be the amount paid by the purchaser and $13 per share will be the amount credited from dividends. Any increase in the dividend rate or any extra dividends will reduce this time and the number of payments accordingly, and any reduction in dividends will make a corresponding increase over forty months.

**The American Insulated Wire & Cable Company**, 954 West Twenty-first Street, Chicago, will erect a one-story copper rod and wire plant, 105 ft. x 300 ft., at South Kedzie Avenue and Drainage Canal, to cost $100,000. It is said that the equipment will involve an investment of $200,000.

**Stephen Hall & Company, Inc.**, formerly at 90 West Street, New York City, have moved to Seventh and Adams Streets, Hoboken, N. J., and the company has been incorporated to manufacture electrical machinery and equipment. Stephen M. Hall is president and Ross C. Pack is vice-president.

**The Ward Manufacturing Company**, 3047 Sheffield Avenue, Chicago, recently incorporated, announces that it will manufacture a line of electric toys, curling irons and grills. R. J. Rich is president of the company.

**The Phoenix Light Company**, 525 Market Street, Milwaukee, manufacturer of electric fixtures, has leased 20,000 sq.ft. of additional floor space at 529 Market Street. Joseph Sable is president and general manager of the company.

**The Rawlplug Company**, manufacturer of a special article for securing screws, has leased an entire floor at 66 West Broadway, New York City, where it will soon combine its general offices, now at 461 Eighth Avenue, and its sales office, now at 48 West Broadway. Stockroom facilities have been increased 600 per cent.

**The Electrical Jobbers' Club** announces the removal of its offices from 47 West Thirty-fourth Street, New York City, to 261 Broadway.

**Hammer & Schwarz**, engineers, announce the removal of their offices to 55 John Street, New York City.

**The Instant Electric Water Heater Company**, Bridgeport, Conn., recently formed, has leased property at Knowlton Street and East Washington Avenue for a new plant for the manufacture of electric water heaters. Equipment will be installed and operations commenced at an early date. The company is capitalized at $250,000 and will succeed to the business of the Bridgeport Manufacturing Company. H. E. Dineson is president.

**The French Battery & Carbon Company**, 2317 Winnebago Street, Madison, Wis., will soon have plans drawn for the rebuilding of the portion of its two-story-and-basement factory, recently destroyed by fire with loss approximating $30,000.

**The Pittsburgh Transformer Company**, Preble Avenue, Pittsburgh, Pa., has purchased property through its president, R. V. Bingay, at Metropolitan and Juniata Streets, at a price stated at $24,000. It is purposed to use the site for extensions.

**The Indiana Manufacturing & Electric Company**, Marion, Ind., recently organized, will manufacture electrical supplies, having taken possession of a plant at Twelfth and Race Streets.

**The Heine Boiler Company**, St. Louis, is enlarging its facilities to manufacture boilers of 2,000 hp. A tank-rolling machine and multiple drill have been ordered.

**The Rumsey Electric Company**, Philadelphia, electric supplies and machinery, announces the appointment of H. D. Baker in charge of its store at 1007 Arch Street.

**The Bakelite Corporation**, New York City, has acquired the plant formerly occupied by the Lake Erie Foundry & Vulcan Company, Painesville, Ohio, and will use it for the manufacture of phenol.

**The Electric Rotary Machine Company**, 40 South Clinton Street, Chicago, has purchased a two-story plant comprising 15,000 sq.ft. of floor space at 3825 West Lake Street.

**The Air-Way Electric Appliance Corporation**, Toledo, Ohio, announces the removal of its export sales department into larger quarters at 220 Broadway, New York City, where a complete array of its line has been arranged. N. M. Simons is the company's export manager.

**The Bartlett Hayward Company**, engineers, announces the removal of its New York office to 1607 Pershing Square Building, Forty-second Street and Park Avenue.

**The New York Electrical Credit Association**, New York City, announces the removal of its office from 47 West Thirty-fourth Street to 261 Broadway.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

Purchase or agency is desired in Morocco (No. 6,254) for electrical goods, etc.

An agency is desired in France (No. 6,256) for transformer oil, circuit-breaker oil, insulating tapes, mica-insulation substitutes and similar products.

Purchase is desired in Matanzas, Cuba (No. 6,300), of electric vacuum oven, medium size, voltage 220.

Purchase is desired in Chihuahua, Mexico (No. 6,309), of all machinery necessary to establish a modern bakery. Prices and illustrated catalogs are desired of gasoline or electrically heated ovens, kneeders, pans, etc.

Purchase is desired in Bilbao, Spain (No. 6,313), of an electric conveyor for iron ore, with a capacity of 1,000 tons per hour, over a distance of approximately 250 m.

SWITCHBOARD AND UNDERGROUND CABLE FOR AUSTRALIA.—Tenders will be received by the Postmaster-General's Department, Sydney, New South Wales, until June 21, for switchboard and multiple-twin underground cable and for telephone switchboard wire.

GENERATING UNIT FOR BULIMA, BRISBANE, AUSTRALIA. — Tenders will be received by the City Electric Light Company, Bulima, Brisbane, until Oct. 31 for one 12,500-kw. turbo-alternator unit at Bulima, Brisbane.

ELECTRIC LAMPS FOR MONTEVIDEO, URUGUAY.—Tenders will be received until June 12 by the State Electric Light Works, Montevideo, Uruguay, for 42,000 metal-filament electric lamps.

EXTENSION OF DISTRIBUTING SYSTEM OF THE MORWELL (AUSTRALIA) POWER SYSTEM.—The Victorian government has decided to appropriate £100,000 to enable the Victorian Electricity Commission, Melbourne, to extend the high-tension transmission lines and distribution lines to county centers desiring electricity from the Morwell plant. Applications have been received from sixteen rural municipalities desirous of taking advantage of the proposed service.

JAPANESE ELECTRIC COMPANY TO RESUME CONSTRUCTION. — The Japanese government, *Commerce Reports* states, is reported to have decided to provide the Taiwan Electric Power Company with funds to enable it to continue construction of the generating plant on which work has been temporarily suspended. The original plans called for a plant of 100,000-kw. capacity, to cost 40,000,000 yen (1 yen = $0.4985). These plans have been modified and it is now estimated that the total amount required will be 30,000,000 yen.

## New Apparatus and Publications

AUTOMATIC CUTTING MACHINE.—The Artos Engineering Company, 306 Milwaukee Street, Milwaukee, has added style "KN" No. 3 to its line of the "Artos" automatic measuring and cutting machines.

FUSE CUT-OUT.—Bulletin No. 201 issued by Schweitzer & Conrad, Inc., 4435 Ravenswood Avenue, Chicago, covers its "S. & C." style "DP" fuse cut-out.

INSULATOR TESTER.—James G. Biddle, 1211-13 Arch Street, Philadelphia, has issued pocket manual No. 1010, entitled "Concerning Insulation Testing, with Special Reference to the Meg."

SLUICEGATES. — The Champion Engineering Company, Kenton, Ohio, is distributing five leaflets illustrating the "Caterpillar" type sluicegates manufactured by the company under "Broome" patents.

INSULATING MATERIALS.—The Mica Insulator Company, 68 Church Street, New York City, is distributing a revised price list and discount sheet covering its electrical insulating materials.

LIGHTNING ARRESTERS.—Bulletin No. 204 distributed by Schweitzer & Conrad, Inc., 4435 Ravenswood Avenue, Chicago, covers the various types of the "S & C" lightning arresters.

LIQUID STARTERS FOR MOTORS.—The Brush Electrical Engineering Company, London, England, has recently brought out a liquid starter for electric motors. This new invention, it is claimed, diminishes resistance gradually and continuously and so eliminates the shocks and sudden variations of resistance characteristic of the usual metallic type of starters.

TRANSFORMER THERMAL INDICATOR.—A new device, known as the transformer thermal indicator, has been placed on the market by the Westinghouse Electric & Manufacturing Company to indicate the temperature of the hot oil in distribution transformers.

BATTERY TEST BOARD.—The Reliance Instrument Company, 1135 West Van Buren Avenue, Chicago, has placed on the market a portable high-rate discharge battery test board for bench use in service stations for testing automobile batteries.

CANOPY SWITCH.—The Arrow Electric Company, Hartford, Conn., has placed on the market a canopy switch with a ratchet handle which, it is stated, can be turned backword without injuring the mechanism.

LIGHTING FIXTURES.—A new lighting fixture, designed particularly for stores, known as "Magic-Lite," has been brought out by the Brascolite Company, St. Louis.

## New Incorporations

THE GROVELAND (FLA.) LIGHT, POWER & ICE COMPANY has been incorporated with a capital stock of $30,000. The officers are Harry Merck, president, and W. M. Cathrae, vice-president.

THE M. & F. POWER COMPANY has been chartered with a capital stock of $35,000 by W. S. Fant, S. Friend and O. H. Bright.

THE ROSCOE ELECTRIC COMPANY, Janesville, Wis., has been incorporated with a capital stock of $5,000 to generate and distribute electricity. The incorporators are William H. Daugherty, Stanley M. Ryan and Paul Grubb.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

AUGUSTA, ME. — The Maine Central Power Company will construct an addition to its substation, 30 ft. x 50 ft.

PORTLAND, ME.—A power house will be constructed at the high school to be built in the Deering district, to cost about $700,000.

MANCHESTER, N. H.—The Public Service Commission has granted the Manchester Traction, Light & Power Company permission to issue $676,700, the proceeds of $639,500 to be used to pay for extensions made prior to Jan. 1, 1923, the remainder to be used for further improvements.

EVERETT, MASS.—The Merrimac Chemical Company, Broadway, will build an addition to its power house.

HOLYOKE, MASS.—The Board of Aldermen has authorized an appropriation of $1,000,000 for a new municipal electric steam generating plant. An appropriation of $100,000 was also authorized by the Aldermen from money now available for the purchase of a site for the proposed new electric plant.

PAWTUCKET, R. I.—Negotiations are under way between the City Council and the officials of the Blackstone Valley Gas & Electric Company for the installation of an ornamental lighting system in the business district.

## Middle Atlantic States

ALEXANDRIA BAY, N. Y.—The installation of an ornamental lighting system, to cost about $50,000, is under consideration by the special lighting committee of the Thousand Island Yacht Club. Further information may be obtained of J. L. Kincaid, 643 West Onondaga Street, Syracuse.

AMSTERDAM, N. Y.—The Adirondack Power & Light Corporation contemplates building a dam and power house on East Canada Creek at Stewarts Landing, to cost about $175,000.

BROOKLYN, N. Y.—The Brooklyn Edison Company will build a substation, 52 x 79 ft., at 179 Hudson Avenue, to cost about $100,000.

BUFFALO, N. Y.—Electric power equipment will be installed in the proposed municipal market building, 50 ft. x 275 ft., to be constructed by the Department of Parks and Public Buildings, on Market Street. Howard L. Beck is architect for the department.

CHARLOTTE, N. Y. — Electric power equipment will be installed in the ice and cold-storage plant to be constructed by the Charlotte Cold Storage Company, to cost about $250,000. John Strobel, E. & B. Building, Rochester, is architect.

CORNWALL, N. Y.—The Cornwall Chemical Company plans to rebuild its power house and factory recently destroyed by fire with loss of about $100,000.

GLOVERSVILLE, N. Y.—The Board of Public Works contemplates the installation of an ornamental lighting system on several streets, to cost from $30,000 to $35,000.

NEW YORK, N. Y. — The Commercial Solvents Corporation, 17 East Forty-second Street, will build a power house in connection with a proposed plant, to cost about $750,000.

OGDENSBURG, N. Y.—The Ogdensburg Power & Light Company plans to erect a building for general operations at Caroline and Ford Streets, to cost about $150,000.

PEEKSKILL, N. Y.—The N. Dains Sons' Company plans to rebuild its power house and lumber plant, recently destroyed by fire, causing a loss of about $200,000.

ROCHESTER, N. Y.—The Rochester Gas & Electric Corporation plans to erect a transformer station at 26 Swan Street, to cost about $40,000.

ROME, N. Y.—The Manufacturers' Power Corporation is considering the construction of a power house on the barge canal and erecting high-tension transmission lines, to cost about $100,000.

TONAWANDA, N. Y.—The R. T. Jones Lumber Company contemplates the construction of a power house in connection with a new lumber plant to be erected on Tonawanda Island.

MILLVILLE, N. J.—The Whitall-Tatum Company will install electric power equipment in connection with the rebuilding of its local glass plant, recently damaged by fire. The loss is estimated at $400,000.

WEEHAWKEN, N. J. — The Cunard Steamship Company, Ltd., 25 Broadway, New York, plans to erect an electric power house in connection with building four 1,000-ft. piers on the Hudson River, to cost about $3,500,000.

BETHLEHEM, PA. — Bids will be received until May 15 for the construction of a power house at the new plant of the Confederated Home Abattoir Company on the Mauch Chunk Road. A refrigerating plant will also be installed. The cost of the entire work is estimated at $350,000. The Gorman-Brown Engineering Corporation, 40 Rector Street, New York City, is engineer.

HOLTWOOD, PA. — The Pennsylvania Water & Power Company is building a 60-cycle system to be completed in 1923. The work will include the installation of two I. P. Morris turbines of 20,000 hp. capacity each; two Westinghouse generators, each of 15,000 kva., 13,200 volts, three-phase; two General Electric frequency changers of 5,000 kw. capacity each; the erection of a double steel tower, 73,000-volt transmission line to York, designed ultimately for 110,000 volts, and a substation at York with an initial transformer capacity of 10,000 kw., where energy will be supplied to the Edison Light & Power Company; also a double-circuit steel-tower, 73,000-volt transmission line to Coatesville, where electricity will be supplied to the Chester Valley Electric Company, to be delivered at a substation to be erected by the latter. James L. Rintoul is treasurer.

MAHONOY CITY, PA.—The Ball Lumber Company plans to rebuild its power house and mill, recently destroyed by fire, with a loss of about $85,000.

PHILADELPHIA, PA.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until May 22 for miscellaneous motor-generator panels and auxiliary equipment. (Schedule 788.)

PHILADELPHIA, PA. — The Largman Gray Company, 3360 Frankford Street, will build a power house at its proposed textile mill on Kensington Avenue, to cost about $300,000.

PITTSBURGH, PA. — The West Penn Power Company has issued $500,000 in capital stock, the proceeds to be used for extensions and equipment in its generating plants.

BALTIMORE, MD.—The United States Industrial Alcohol Company, Curtis Bay, plans to install a power house in connection with a new plant to cost about $700,000.

BALTIMORE, Md.—Plans have been prepared by the Board of Works, for a central power plant for city service, to be built in conjunction with a police station at Lexington and Gay Streets, to cost about $500,000. Lawrence H. Fowler, 307 North Charles Street, is architect.

HAGERSTOWN, MD. — The Maryland Public Service Company was recently organized by officials of the American Water Works & Electric Company, New York, to take over the systems of the Potomac Public Service Company, Hagerstown, and the Cumberland (Md.) Edison Company. Bonds to the amount of $3,983,000 have been authorized to carry out the consolidation and for extensions and improvements to the systems.

CHARLESTON, W. VA.—Electric power equipment, refrigerating machinery, etc., will be installed in the new market building to be erected by the Charleston Market Company, to cost about $400,000.

MORGANTOWN, W. VA.—Preparations are being made by the West Virginia Power & Transmission Company, a subsidiary of the West Penn Power Company, for the construction of a hydro-electric plant on the Cheat River at State Line. Rights of way for a transmission line from the proposed dam to Morgantown and Fairmont are being purchased.

HOPEWELL, VA.—The Hopewell China Company contemplates rebuilding its power plant, recently destroyed by fire with loss of about $100,000.

SHENANDOAH, VA. — The Norfolk & Western Railway Company, Roanoke, plans to install a power house at its proposed local car and locomotive repair shops, to cost about $450,000.

WASHINGTON, D. C.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, until May 22 for 250 transformer coils and 100 mica condensers. (Schedule 787.)

## North Central States

CARO, MICH.—The Great Lakes Company, Bad Axe, has purchased the local electric plant, owned by the Consumers' Power Company, Jackson.

ERIE, MICH.—The Père Marquette Railroad Company, Detroit, will build a power house in connection with its proposed local car and locomotive shops, to cost about $1,000,000.

KALAMAZOO, MICH.—The El-Mora-Lee Paper Company, 839 Lake Boulevard, Kalamazoo, Mich., will build a power house in connection with its proposed paper mill in Howlandsburg, to cost about $100,000.

RED JACKET, MICH.—The installation of an ornamental lighting system on Fifth and Oaks Streets is under consideration.

CLEVELAND, OHIO.—Bids will be received at the office of the commissioner of purchases and supplies, City Hall, until May 18 for cedar poles for the division of light and power. Separate bids will be received at the same time and place for electric meters, and also for fiber conduit, for the division of light and power.

FREMONT, OHIO.—A company has been organized by farmers along the Port Clinton road for the purpose of securing electric service from the Ohio Light & Power Company.

SHELBY, OHIO.—The Council has appropriated $6,500 for equipment for the municipal electric plant, including two boilers of 300 hp. capacity each.

FLEMINGSBURG, KY.—The Maysville Gas Company contemplates the erection of an electric transmission line to Flemingsburg and purchasing the local distribution system. The city at the present time is without street-lighting service.

WHITESBURG, KY. — The Blue Ridge Diamond Coal Company plans to install electric power equipment at its coal properties. A lumber mill with power house is under consideration.

CLINTON, IND. — The Wabash Valley Electric Company is negotiating for the purchase of the properties of the Martinsville Gas & Electric Company, Spencer Light, Power & Water Company, Putnam Electric Company, Cayuga Electric Company, Roachdale Electric Company, Gosport Electric Company and the Morgan County Light & Power Company. The systems will be merged and extensions and improvements made. Bonds to the amount of $1,561,700 have been authorized to carry out the consolidation and to provide funds for expansion.

INDIANAPOLIS, IND. — Arrangements are being made by the Lavelle Foundry Company, Michigan Street and the Belt Railway, for equipping its plant for electrical operation.

NEW HARMONY, IND.—Plans are being considered for improvements and extensions to the municipal light and power plant, to cost about $60,000.

VINCENNES, IND.—The Indiana Power Company has issued $1,000,000 in capital stock, the proceeds to be used for extensions and improvements, including a 10,000-kw. addition to the local plant.

BLOOMINGTON, ILL.—Bids, it is reported, will soon be asked for the installation of an ornamental lighting system on Washington Street, to cost $6,736.

EDWARDSVILLE, ILL. — Plans are under consideration to replace the arc lamps in the business district (covering about 2 miles) with an ornamental lighting system

LINCOLN, ILL. — Extensive improvements are contemplated by the Lincoln Water & Light Company involving an expenditure of about $143,000. Contracts have been placed for a 1,500-kva. turbo-generator and condenser.

ST. CROIX FALLS, WIS.—The Railroad Commission has granted the St. Croix Falls Improvement Company permission to raise and rebuild the Nevers Dam across the St. Croix River. The new dam, it is estimated, will develop about 30,000 hp.

SALEM, WIS. — The Carey Electric & Milling Company, Wilmot, will make extensions and improvements to its local system as suggested by the Railroad Commission.

SHEBOYGAN, WIS.—The Eastern Wisconsin Electric Company contemplates extensions and improvements to its local properties involving an expenditure of about $200,000. The plans include an addition to power house and installation of additional generating units.

WEST ALLIS, WIS.—The City Council has authorized the installation of an ornamental lighting system on Greenfield Avenue, to cost about $11,000.

FERGUS FALLS, MINN. — Among the improvements contemplated by the Ottertail Power Company this summer is the construction of two large power dams on the Otter Tail River at Fergus Falls and the erection of another large steam power plant. The cost of the work is estimated at about $500,000.

MINNEAPOLIS, MINN.—Plans are being considered by the Board of Park Commissioners for the erection of 244 electric lamp standards along Minnehaha Parkway, to cost about $35,000.

ST. PAUL, MINN.—Improvements contemplated by the St. Paul Gas Light Company during 1923 include replacing six rotaries of 1,500 kw. capacity with two motor-generator sets having a total capacity of 2,000 kw., installing three 300-kw. transformers and starting construction work on the first 25,000-kva. unit of its proposed new steam-driven generating plant. F. C. Hoffman is secretary.

SLAYTON, MINN.—The Slayton Power Company has contracted with the Northern States Power Company for electricity, the service to begin about June 1. F. H. Eddy is owner of the local system.

CENTERVILLE, IOWA. — The Iowa Southern Utilities has issued $1,000,000 in bonds, part of the proceeds to be used for extensions and improvements.

RIVERSIDE, IOWA.—The Sioux (Iowa) City Brick & Tile Company plans to build a power plant at its proposed local factory, to cost about $100,000.

SIOUX CITY, IOWA. — Options have been obtained by the Sioux City Gas & Electric Company on about 15 acres of land in the North Riverside section of the city as a site for its proposed new plant.

HOPKINS, MO.—The Maryville Electric Light & Power Company is planning to extend its transmission line to Hopkins to furnish electrical service here. The local plant was recently burned down.

GREENFIELD, MO.—The South Missouri Power Company plans to erect a transmission line to Golden City to furnish electricity there. The company also contemplates extending its service to South Greenfield, Lockwood and Everton.

ORAN, MO.—At an election to be held May 15 the proposal to issue $23,000 in bonds for installation of an electric lighting system will be submitted to the voters.

SIOUX FALLS, S. D.—The Minnesota Electric Distributing Company and the Tri-State Utilities Company, Eldora, Iowa, are promoting the erection of a high-tension transmission line from Gayville, S. D., to Wynot, Neb., from which point two branch lines will be built. Practically every town in Cedar, Dixon and Knox Counties will be served by the new lines. Arrangements are being made to take over the electric plant now furnishing electricity in these localities.

## Southern States

GREENSBORO, N. C.—Plans are being prepared for a power plant for the Agricultural and Technical College to cost about $55,000. Harry Barton, Greensboro, is architect.

MARION, N. C.—The Marion Lake Club plans to install an electric light and power plant.

OAKBORO, N. C.—The Oakboro Cotton Mill plans to install a power plant in connection with a proposed local textile mill, to cost $225,000.

WALNUT COVE, N. C.—Plans are under consideration by the Council for the installation of a municipal electric light plant

WASHINGTON, N. C.—The J. M. Swindell Company will build a power house in connection with a proposed packing factory and ice plant, to cost about $100,000.

CLEARWATER, FLA.—Plans are being considered by the Clearwater Cooperage Company for the installation of a power plant in connection with a proposed local plant, to cost about $100,000. C. E. Murray is president.

CRESTVIEW, FLA.—Bids will be received by the Common Council until May 28 for a 40-kw. generator, exciter, switchboard and equipment for distributing system, etc., for a municipal electric plant. J. D. Carter, Geneva, Ala., is engineer.

GREENVILLE, FLA.—Bonds for $30,000 have been voted for extensions and improvements to the municipal lighting system and waterworks.

MIAMI BEACH, FLA.—Bonds to the amount of $20,000 have been voted for the installation of an ornamental lighting system.

MILAN, TENN.—Plans are under consideration for extensions and betterments to the municipal electric plant, to cost about $40,000.

HEFLIN, ALA.—W. M. Dobson, Wedowee, it is reported, contemplates installing an electric plant in Heflin. The local electric plant was recently destroyed by fire.

PELHAM, ALA.—The Superior Lime & Hydrate Company contemplates the construction of a power house at its local plant.

LITTLE ROCK, ARK.—The Arkansas Central Power Company, recently organized to take over the local properties of the Little Rock Railway & Electric Company, has issued $2,500,000 in bonds, part of the proceeds to be used for extensions and improvements.

BATON ROUGE, LA.—The Baton Rouge Electric Company contemplates extensions and improvements during the next eighteen months, to cost about $1,000,000. The plans include an addition to the local power plant to cost approximately $300,000. New equipment, including a 3,000-kw. generator, will be installed.

LAFAYETTE, LA.—The Southern Pacific Railroad Company plans to build a power house at its new local shops now in course of erection.

KIEFER, OKLA.—The Oklahoma Gas & Electric Company is planning to erect a transmission line from Kiefer to Nuyaka, via Mounds, a distance of 20 miles.

McALESTER, OKLA. — The Choctaw Power & Light Company contemplates erecting a high-tension transmission line from McAlester to Savanna, Kiowa, Stringtown, and possibly to Atoka, a distance of about 50 miles.

AMARILLO, TEX.—The City Light & Water Company has contracted with the municipality for the installation of an ornamental lighting system in the business district.

DEWEYVILLE, TEX.—The Peavy-Moore Lumber Company plans to construct a power house in connection with a new lumber mill, to cost about $500,000.

URBANA, TEX.—The Urbana Sand & Gravel Company will install a power house at its plant. The equipment will include a 60-kw. generator.

## Pacific and Mountain States

TACOMA, WASH.—Plans are being prepared by J. L. Stannard, engineer, Balboa Building, San Francisco, for two power houses, one of 30,000 hp. capacity, the other of 45,000 hp., storage dam, etc., and transmission lines in connection with the Lake Cushman power project for the city of Tacoma.

VANCOUVER, WASH.—Work will soon begin by the Pudget Sound Power & Light Company, Seattle, on the erection of a high-tension transmission line between Woodland and Vancouver.

YARDLEY, WASH.—The Western Cedar Pole Preserving Company contemplates building a power plant in connection with its local plant, to cost about $100,000.

ASTORIA, ORE. — Surveys are being made by the Crown Willamette Paper Company with a view of developing the water power at Young's River Falls to operate its pulp mill there.

ASTORIA, ORE.—The installation of a new local heating and power plant is under considerataion by the Consumers' Central Heating Company, Tacoma, Wash.

BAKER, ORE. — The Eastern Oregon Light & Power Company plans to build a 1,500-hp. steam-driven electric plant in Baker, estimated to cost about $100,000.

MILTON, ORE. — Permission has been granted to K. C. Harlan, Walla Walla, Wash., to utilize the water power of the Walla Walla River above Milton. Mr. Harlan proposes to furnish water to irrigate 10,000 acres of land and to develop 4,000 hp.

EUGENE, ORE.—Plans have been prepared for the construction of a new power house for the University of Oregon, to cost about $75,000. Bids, it is understood, will soon be asked for the work.

NORTH BEND, ORE.—The City Council is considering the establishment of a municipal electric light plant and waterworks system.

ROSEBURG, ORE.—Plans are being prepared by the City Council for the installation of an ornamental lighting system in the business district, to cost about $10,000.

AUBURN, CAL.—The Bear River Water & Power Company has been granted permission to construct a hydro-electric generating plant on the Bear River.

MODESTO, CAL.—The Modesto Irrigation District has been granted permission by the State Water Board to construct and operate a 17,000-hp. hydro-electric power plant on the Tuolumne River, Stanislaus County, to cost about $360,000.

SAN FRANCISCO, CAL.—Bids will be received by the Board of Public Works of the city and county of San Francisco, San Francisco, until May 23 for furnishing and installing steel penstocks and accessories for the Moccasin Creek power plant, contract No. 91, Hetch Hetchy water supply. Specifications may be obtained at the office of M. M. O'Shaughnessy, city engineer, City Hall.

## Canada

VICTORIA, B. C.—The British Columbia Electric Company contemplates extending its transmission line from Bamberton to the Duncan, Cowichan and Ladysmith districts.

GLACE BAY, N. S.—The Town Council is considering an appropriation of $32,950 for extensions to the municipal electric system.

PORT ARTHUR, ONT.—The erection of a second transmission line from Cameron Falls to Port Arthur and the installation of an additional generating unit is under consideration by the Hydro-Electric Power Commission.

QUEBEC, QUE.—Plans have been submitted to the Provincial Cabinet by the Running Streams Commission for the construction of a dam on the Metis River in Matan County, to cost about $200,000. The Compagnie du Bas St. Laurent is interested in the project.

QUEBEC, QUE.—The Lower St. Lawrence Power Company has petitioned the Public Service Commission for permission to erect electric transmission lines in Rimouski and Matane Counties.

QUEBEC, QUE.—The Quebec Provincial Government has awarded the Des Quinze power lease to W. Alexander Fasken, Toronto, a director of the Northern Ontario Light & Power Company, Ltd., Cobalt, Ontario, at an annual rental of $80,100. The Des Quinze power project consists of fifteen rapids near the head of Lake Temiskaming and is capable, it is said, of developing 60,000 hp.

## Electrical Patents

**Announced by U. S. Patent Office**

(Issued April 17, 1923)

1,452,267. CONNECTING DEVICE FOR ELECTRIC CIRCUITS; S. M. Esler, Chicago, Ill. App. filed Aug. 7, 1919. Two-way adaptor for lamp sockets.

1,452,269. TELEPHONE-EXCHANGE SYSTEM; C. L. Goodrum, New York, N. Y. App. filed April 17, 1920. Machine-switching selecting means.

1,452,277. TELEPHONE SUBSTATION SET; K. S. Johnson, Jersey City, N. J. App. filed Oct. 8, 1917. Arranging elements of local battery set for maximum efficiency.

1,452,281. METALLIZING ARTICLES; Q. Marino, Hampstead, London, England. App. filed Sept. 10, 1921. Electrodepositing metallic coating on article.

1,452,304. COLLAPSIBLE ELECTRIC HEATER; E. J. McCormack, San Francisco, Cal. App. filed July 13, 1921. Of reflector type.

1,452,311. HEATING DEVICE FOR LIQUIDS; C. E. Parkhurst, Somerville, Mass. App. filed March 11, 1922. Automatic temperature control.

1,452,321. ADAPTER. L. Stendahl, Fairfield, Conn. App. filed March 31, 1922. For use in lamp sockets

1,452,323. TOLL TRUNKING CIRCUITS FOR MACHINE-SWITCHING TELEPHONE SYSTEMS; R. L. Stokely, Floral Park, N. Y. App. filed March 1, 1921. Method of collecting and returning coins to subscribers.

1,452,327. POWER-TRANSMISSION ARRANGEMENT; M. E. Thompson, Ridgway, Pa. App. filed Dec. 20, 1919. Magnetic coupling for engine and motor drive in submarines.

1,452,334. TELEPHONE RECEIVER; C. T. Baisley, North Edgecomb, Me. App. filed May 11, 1922. Watchcase type.

1,452,339. ELECTRICAL DISCHARGE DEVICE; R. A. Helsing, East Orange, N. J. App. filed May 28, 1918. Tubes of audion type which function as generators.

1,452,399. RADIO VARIABLE RHEOSTAT; H. W. Tompkins, Greensburg, Pa. App. filed Aug. 2, 1922.

1,452,472. CONTROLLER FOR MOTORS; C. W. Plehaty, White Plains, N. Y. App. filed Jan. 25, 1922. Manually operated starting box.

1,452,484. METHOD OF GUNFIRE CONTROL FOR BATTLESHIPS; E. A. Sperry, Brooklyn, N. Y. App. filed Sept. 30, 1916. Gyroscopic apparatus.

(Issued April 24, 1923)

15,584 (reissue). DIRECTION SIGNAL FOR AUTOMOBILES; W. W. Lincoln, Washington, D. C. App. filed Oct. 7, 1920.

1,452,500. BURGLAR-ALARM APPARATUS; B. Galerman, Philadelphia, Pa. App. filed Oct. 15, 1918.

1,452,511. 1,452,512 and 1,452,513. ELECTRIC RIVET HEATER; W. S. Johnson and J. W. Sheffer, Berwick, Pa. App. filed Aug. 17, 1920. Transformer for heating rivets and hood for protecting heater against elements.

1,452,527. TRANSMITTING APPARATUS FOR ELECTRIC TELEGRAPHS; L. M. Potts, Baltimore, Md. App. filed Dec. 14, 1915. Motor-driven telegraph transmitter.

1,452,528. BRAKE; J. M. Rohlfing, Plainfield, N. J. App. filed April 15, 1922. Electrically operated motor brake.

1,452,550. CIRCUIT INTERRUPTER; O. H. Eschholz, Wilkinsburg, Pa. App. filed Aug. 18, 1921. Water resistance inserted to reduce current.

1,452,573. ELECTRODEPOSITION OF TIN; L. D. Simpkins, Brooklyn, N. Y. App. filed Feb. 10, 1922. Electrolytic bath containing tin-salt solution, beta-naphthol and a colloid.

1,452,574. CIRCUIT INTERRUPTER; J. Slepian, Wilkinsburg, Pa. App. filed June 29, 1918. Resistance inserted to reduce current.

1,452,587. REGULATING AND CIRCUIT-CONTROLLING APPARATUS; E. J. Blake, Buffalo, N. Y. App. filed Oct. 14, 1920. For storage battery-generator lighting equipment.

1,452,589. ELECTROLYTIC CELL; D. A. Brading, Chicago, Ill. App. filed Sept. 23, 1922. For making hydrogen and oxygen gas.

1,452,590 and 1,452,591. ELECTRICAL MEASURING INSTRUMENT; I. W. Brogger, Newark, N. J. App. filed April 26, 1919. Ammeter of solenoid type.

1,452,610. ELECTRICAL CONDENSER; M. Klosner, New York, N. Y. App. filed Sept. 2, 1920. Variable plate condenser.

1,452,615. WIRE-ASSEMBLING MACHINE; E. A. Pigeon, Akron, Ohio, App. filed May 8, 1920. Machine cuts and assembles wires for various circuits in automobile.

1,452,651. TARGET FINDER FOR FIREARMS; C. H. Norrlin, New York, N. Y. App. filed Oct. 15, 1921. Flashlight attached to barrel.

1,452,666. DEVICE FOR THE COOLING OF ELECTRIC APPARATUS BY THE CIRCULATION OF LIQUID THROUGH THE CONDUCTORS; P. G. M. Toulon, Paris, France. App. filed May 2, 1922. Fluid-cooled secondary winding of a transformer so combined with fluid-cooled anodes of vapor rectifier that cooling of both is effected simultaneously.

1,452,678. APPARATUS FOR REMOVING THE DIVISION PLATES FROM ICE-CREAM RECEPTACLES; H. Dilas, Bay City, Mich. App. filed Jan. 12, 1922. Plates heated electrically.

1,452,681. AUTO SIGNAL; M. Fujimoto and T. Okawa, Portland, Ore. App. filed May 21, 1920. Rear-direction signal apparatus.

1,452,688. VOLTAGE-CONTROLLING DEVICE FOR DYNAMOS; G. C. Hubble, Bonners Ferry, Idaho. App. filed Dec. 2, 1921. Automatic or manual control of field current.

1,452,737. SIGNALING DEVICE; F. M. Hill, Chicago, Ill. App. filed Oct. 1, 1917. For railway crossings.

1,452,752. PANELBOARD CONSTRUCTION; E. A. Olley, Syracuse, N. Y. App. filed June 13, 1918. Circuit-carrying parts assembled as unit before attaching to panelboard base.

1,452,762. ELECTRIC SEAM-WELDING MACHINE; E. Schroder, Berlin, Germany. App. filed March 15, 1920. For welding longitudinal seams of tubes.

1,452,781. WELDING ROD; F. M. Becket, Niagara Falls, N. Y. App. filed June 28, 1921. Iron alloy containing carbon, manganese and silicon.

1,452,806. STORAGE-BATTERY VENT; N. M. Hopkins, New York, N. Y. App. filed May 31, 1921. Prevents leakage of electrolyte.

1,452,813. METHOD OF DECOMPOSING MIXED SALT SOLUTIONS; H. Pauling, Berlin-Grunewald, Germany. App. filed Aug. 3, 1921. By electrolysis.

1,452,814. INCLOSED-SWITCH CONSTRUCTION; C. F. Platt, Bridgeport, Conn. App. filed June 27, 1922. To facilitate installation and replacement of fuse plugs without opening box.

1,452,827. TELEPHONE DEVICE; L. de Forest, New York, N. Y. App. filed Nov. 22, 1919. Combined loud speaker and table lamp in which shade acts as diaphragm.

1,452,849. WIRELESS TRANSMITTING STATION; H. J. Round, London, England. App. filed Dec. 13, 1921. Sending different wave lengths simultaneously.

1,452,850. TELEPHONE APPARATUS; L. Schmidt, Brooklyn, N. Y. App. filed June 26, 1922. Loud-speaking receiver for wireless telephone.

1,452,851. HEAD RECEIVER FOR TELEPHONES; L. Schmidt, Brooklyn, N. Y. App. filed Sept. 30, 1922. Head band for two receivers.

1,452,857. SYSTEM OF VOLTAGE CONTROL; L. S. Uphoff, U. S. Army. App. filed June 26, 1919. For use with X-ray machines.

1,452,877. SYSTEM OF DISTRIBUTION; G. E. Hulse, Newark, N. J. App. filed Dec. 9, 1918. Railway-car battery-generator lighting equipment.

# "Excess Varieties"

A WELL-KNOWN manufacturer of electrical supplies recently made the statement that 80 per cent of the articles produced by his firm were carried in its catalog for the purpose of "window dressing." The other 20 per cent, he said, represented practically 85 per cent of the entire volume of his sales. On the theory that this great array of varieties will discourage new competitors from entering the field, four out of every five devices that he makes and sells are forced on the market by the natural influence of their being listed as standard in his catalog.

Since these superfluous varieties are offered, it is no more than natural that central stations, contractors, dealers and industrial plants should order many of them. Jobbers carry them. And the manufacturer himself continues to produce them in small quantity to fill scattered orders that might just as well call for some other device of similar character.

AT THE present time American manufacturers in a wide range of industries are engaged in a broad program of simplification. It is their belief that duplication of product causes waste and that the elimination of dead wood in any line effects economy. Right down the line from the factory to the consumer the production of excess varieties lays a burden of extra cost upon every one who buys or sells or handles them. It means excess patterns, excess dies, excess operations in the making, excess stock for manufacturer, wholesaler and retailer, excess orders, excess bills, excess accounting; and in the case of electrical materials it adds to the cost of installations. It impedes the electrical business. Therefore as a principle and a policy it concerns the entire electrical industry.

It is, of course, quite natural that every manufacturer should desire to discourage newcomers from entering his field and unnecessarily increasing the competition for existing business. Excessive competition between manufacturers and wholesalers who produce and sell duplicate lines of too many varieties in too small quantities undoubtedly is one of the bad features of the present situation. But is there not a better way to go about it?

BY THE simplification of his line and by the mass production of more standardized staples a manufacturer can reduce his cost and his price and protect his business far more effectively than by endeavoring to frighten off new competitors by camouflage in the form of a catalog loaded down with obsolete, duplicate or other excess varieties. There is greater security for the manufacturer in following along economic lines and keeping costs down in the public interest than in any form of repellent "window dressing" that imposes added burdens of expense on the entire industry. Efficiency is the greatest armor in the world.

It is encouraging therefore to observe the amount of attention which this broad problem of simplification is right now receiving from both electrical manufacturers and jobbers. It will be a great service to the electrical business if together they can perfect a program that will relieve the market of the present glut of excess varieties in many of our important commodities.

# Lewis Taylor Robinson

*A leading exponent of standardization who is noted for his courtesy, common sense and understanding of human relations.*

STANDARDIZATION came into existence as a slogan and a fact only after unusually strenuous efforts to co-ordinate the opinions and practices of engineers and manufacturers had been made by a few farseeing leaders. In this work the outstanding requirements were persistency, perspective, enthusiasm and an understanding of psychology. Lewis T. Robinson proved to have these traits to an unusual degree, and his winning personality, his sound common sense and his broad perspective materially helped the work of standardization over many serious obstacles.

Born in Springfield, Mass., Oct. 20, 1869, he was educated at Reading and Lynn and then started his career in the electrical industry by taking charge of the standardizing laboratory of the Thomson-Houston Electric Company. In 1891 he became a member of the testing firm of Whitmore & Robinson and in 1896 took charge of the standardizing laboratory of the General Electric Company. Later he was promoted to his present position as engineer in charge of the general engineering laboratory. During this period he has contributed to the engineering development of instruments and machines and has exercised executive supervision with unusual success. Democratic, good-humored, witty and forbearing, he has encouraged and inspired his coworkers and "humanized" the engineering activities of the company.

He has found time to contribute valuable services to the industry as a whole and has held high offices in many engineering organizations. He served as a vice-president of the A. I. E. E. in 1916-18 and 1920-21 and is a past-chairman of the standards committee. His services were in demand at the founding of the Federated American Engineering Societies, and he maintains close contact with many committees working for the advancement of the industry. Mr. Robinson is the author of important papers and is active in the N. E. L. A. He is a member of the United States National Committee of the International Electrotechnical Commission and is on the committee on insulation of the National Research Council.

Untiring worker and self-made man, Lewis T. Robinson has a host of friends and a record of achievements that have made for him a secure position both as man and leader in the annals of the electrical industry.

# Editorial Comment

## The Forthcoming Electric Light Convention

LIKE a banquet table fully set, the program for the convention of the National Electric Light Association is filled with delectable things. Statesmen, bankers, captains of industry, public service commissioners and others will address the various meetings in addition to representatives from the industry itself. Replete with all manner of reports and papers as these annual gatherings usually are, this year's program seems remarkably so. At no period of the association's history has interest in its affairs been keener or its work more productive, and naturally this condition is reflected in the annual convention. A record-breaking attendance is anticipated, for, aside from the attractions which New York affords, the wealth of material represented in this year's program provides an added incentive for electrical men from all parts of the country to be present. Certainly no phase of the electric light and power business has been overlooked, and all told the convention should go down in history as one of the greatest the industry has ever held.

## Is the Real Voice of Your Company Mute?

WHAT is the difference between advertising and publicity? Some central-station men may think that it doesn't matter much, that this is just a technicality. Not so. And the important difference is this, that advertising is a sales function, whereas publicity is in reality an executive function. Broadly, the distinction may be made that advertising is a message from the company to its customers about something that the company wants to sell, while publicity is a message from the company about itself. And the man who speaks thus for the company to the community should be an executive.

In too many utilities the president and the general manager retire into modest seclusion. They make no speeches to their townspeople. They write no personal letters to their customers. They express themselves directly in no printed messages. They forget that they head the most vital industry in the community, that they are the two men whom the public look upon as "the company." They keep their personalities out of the picture, whereas what the situation needs is a personal intimacy with the public. The words of the company they leave entirely to the articulation of the sales manager, whose costs they scrutinize, holding him strictly to account for sales. And so the company's speech is neither free nor frank. It does not express the thinking or the character of the executive, who is seen and met only in chance confidential conversations with individuals in his private office.

By contrast, those company executives who have taken the plunge and have appeared to their public in ways mentioned here have reaped the benefits manyfold and are enthusiastic supporters of such action.

Executives like frank opinion and plain speaking from the men of their own organizations that they may learn their measure and have the "feel" of their judgment and their self-reliance. By the same token does the community desire to hear and see and know these chief men who operate its central station and are therefore in an entirely real sense the employees of the public.

The voice of the chief executive should be recognized and listened to with confidence in the community and not habitually held to speak in secret to those alone who come to him. The rest of the people, for whom he is also working, are quite as interested and are entitled to hear no less.

## Putting Confidence in Young Blood

NO ARGUMENT is necessary to prove that unless the electrical industry attracts youthful workers to enter its service and embrace its opportunities from one year's end to another it will become moribund. Progressive executives act upon this fact when they open the doors of their plants and factories, stores and offices to ambitious young employees and so infuse new blood into established concerns. Not a little has been said of late about the importance of pecuniary compensation in keeping younger employees contented in the utility and other fields in which electricity plays a vital part. While the money reward, or at least the outlook in that direction, is undeniably important, yet to less mature workers there are other considerations quite as weighty and not seldom more prevailing than the question of present salary.

The rapid progress of virtually every phase of work in the electrical industry presents an appeal to younger employees which should be capitalized with insight by their superiors. In not a few cases the failure of executives to permit responsibility to remain upon qualified employees' shoulders has led to the loss of valuable and promising human material to other industries. The policy of taking away a particular job from a young man just as he reaches its thoroughly interesting stage is responsible for the departure of some workers into other fields, and the same remark applies to the policy of keeping employees in the dark as to the reasons for company practices, to a failure to give credit to the privates and non-commissioned workers of the industry for significant achievements, and to a lack of interest by executives of lower rank in the prospects and ambitions of their personnel. Even the dropping or irregular publication of an accepted company house organ is a blow to the morale.

Every modern business faces the problems hinted at, but surely in the electrical industry there is little

excuse for treating the ambitious employee as a mere cog in the wheel. Whenever he or she is doing significant work, let that significance be known to the doer. It may be a compilation of costs for presentation in a rate case or a computation of voltage drops in feeders as a part of an economic study of equipment development; it matters not which, but special effort may well be made to avoid submergence in a sea of routine too deep for getting a view of the bearings of the organizational craft as it moves forward into areas of greater service. Wise supervision is one thing in holding the employee's interest, but a policy of keeping him outside a proper knowledge of what is going on is quite another.

### Capitalize Maintenance Expense to Ascertain Value of Reliability

ALTHOUGH purchasing agents of some operating companies may be tempted to buy the cheapest equipment available so long as it is not notoriously inadequate, no operating engineer who has a voice in purchases will sacrifice reliability to a saving in first cost. Too many contingencies arise in practice, even when the greatest precautions are taken, to permit him to slight the factor of reliability. None the less, this factor is often looked upon as an intangible consideration, and hence the relative values of transformers are likewise assumed to be indefinite. Whatever truth there may be in this assumption, a very good basis for determining what can be paid for increased reliability can be obtained by keeping records of unit transformer repair and replacement expenses for different classes of equipment used. Capitalized and added to the first cost of the transformers, these expenses will permit the calculation of a more nearly true value of the relative cost of transformers than the initial cost would indicate.

### Standardization Rarely Attempted for Transmission Towers

APPARENTLY basic differences in design and operating conditions prohibit any great amount of standardization in line-tower construction. This fact is clearly brought out in the article in this issue by H. L. Sharp, there being a considerable difference in the towers which this one company recently installed on several different lines. One element in the situation which influences variety of design is a desire to determine the relative merits of different designs in view of the lack of field data regarding the use of steel towers over long periods of time.

The transmission structures built in recent years have usually been required to satisfy only some general conditions. It seems to be the practice that double-circuit tangent towers, for example, should stand where two of the six conductors are broken, angle towers should not fail when more than two of the six conductors are broken or a corner load is placed on them, and dead-end or anchor towers should carry the load accompanying the dead-ending of all line wires or unusual corner loads. From the article it is evident that the line described has, for its tangent towers, flexible frames with no longitudinal strength, instead of "intermediate" towers, and that the semi-anchor towers are equivalent in loading to the tangent towers used in the usual line. This installation serves to illustrate the lack of agreement among engineers in regard to the broken-wire condition of loading. Indeed, there is considerable doubt whether the assumption that all wires may be broken, at a crossing for example, is not in conflict with the assumptions on which the tower lines are designed.

Another interesting feature of the design is the use of double-double insulators at railroad crossings. Some designers prefer the type of construction used at the semi-anchor towers, but it may be that either a railroad specification or mechanical necessities caused the installation of the double-double insulators. Moreover, the ground wires are described as made of double-galvanized, high-strength crucible steel cable, and since, presumably, they are of greater strength than the conductors, a question arises as to whether a lower grade of steel would not have been easier to handle in the field. It would also be interesting to get a definition of the term "double-galvanized," as differences of opinion on this subject exist among transmission line engineers.

While it is not always feasible to carry a design from one line for use on another, yet surely the detailed record of design and construction practices used on the Niagara, Lockport & Ontario system should prove very valuable to engineers working on lines in other territories.

### Successful Automatic-Plant Operation in New England

NEARLY a year's experience with automatic operation at the Searsburg hydro-electric plant of the New England Power Company lies back of the article by E. B. Collins published elsewhere in this issue, and it is gratifying to record the success of the installation from both the labor-saving and the reliability standpoint. The plant is one of the largest automatic generating stations in the country; it is situated on a stream of unusually interesting characteristics and development, and it forms a part of a system noted for skilled engineering and up-to-date operating methods. Searsburg has been running more than 90 per cent of the time since last summer. No important changes have been required in its electrical equipment and only minor alterations in its mechanical features.

It is interesting to note how some of the problems in design which confronted the company's engineers and those of the manufacturers have been worked out in this station to insure maximum convenience and reliability of operation. These were outlined by Messrs. Conger and Dow of the New England company in a paper presented before the 1921 fall convention of the New England Division of the N. E. L. A., and not a little ability in anticipating requirements was then manifested. Some attendance was necessary at the plant in the past winter on account of its remoteness from populous centers and because of rack clearing and other factors not directly governed by equipment design, but full automatic operation has been generally practiced, with time-clock and float control and loading according to predetermined settings of governing equipment. Instrumental readings have been telephoned to other points, and the cost of providing for their automatic transmission has not yet been thought warranted.

Governor regulation operates within a range of about one-half cycle above and below normal, but since it is desirable that Searsburg shall carry a fairly uniform load while in operation the governor is designed to do

somewhat less than its proportional share of regulating. The speed of gate opening is cushioned by a dash-pot mechanism, and in starting about two and one-half minutes is required to reach full gate opening. The plant is provided with a surge tank capable of taking care of disturbances when full load is dropped instantaneously or when there is an instantaneous load increase of 50 per cent. The dash-pot mechanism is adjustable for a five-minute maximum opening period. The co-ordination of gate operation and brake service appears to have been carefully worked out, and the use of strained water instead of oil in the latter is giving good results. Other features include provision for cutting off water from the scroll case for inspection, repairs or shutdown; arrangement for automatic stopping of the unit in case of overheated bearings or insufficient governor pressure, and means of operating the generator as a motor for power-factor correction if desired, although its remote location with respect to the system load center renders this a rare necessity. No attempt has been made to use automatic flashboards, but as the headworks are provided with a power-driven submerged floodgate, the work required in connection with flashboards is greatly reduced.

By and large, the installation appears to be giving an excellent account of itself and it is safe to say that, young as the art of automatic control is, its usefulness is being demonstrated in practical service with increasing emphasis. A plant of the rating and head illustrated by Searsburg shows that the possibilities of automatic operation will not long be confined to stations of a few thousand kilowatts if the general conditions are favorable to the use of this new but highly developed type of apparatus.

## How Good Public Relations Are Not Built

A STORY known as the "bedbug story" is going the rounds among after-dinner speakers which has a good moral for utility public relations men. A man encountered bedbugs in a sleeping car, so the story runs, and wrote a very indignant and scathing letter to the proper official. A kindly, courteous letter of apology, with an explanation that the occurrence was most unusual and that every precaution was taken against it, was received, which made the indignant passenger feel that there were some real people in the world after all. Then he discovered his original letter attached to the reply, and across it was written in blue pencil: "Send this guy the bedbug letter." The complainant's state of feeling can be imagined better than described.

The "bedbug letter" type of public relations work, which has only been hung on the sleeping car as a convenient vehicle, is the reason why some men make a failure of winning the public. Good public relations are built only on sympathetic feeling, an ability to understand the other fellow's problems and an earnest effort to prevent the incidents that build ill will. The "send this guy" attitude strikes a note of insincerity which, when discovered, makes existing ill will twice as bitter. Form letters, set rules for pacifying a complaining public and all such devices are a failure. Personal contact and efforts to correct bad situations mean endless work and sometimes drudgery, as well as the most rigid personal honesty, but they are the important factors in keeping on good terms with the public.

## Problems Yet to Be Solved in Carrier-Current Telephony

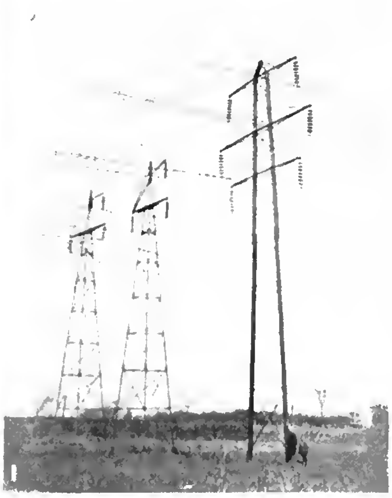
IN COMPARING experiences obtained with carrier-current telephony over power lines one should differentiate carefully between the operating conditions. Results do not depend alone on the sending and receiving sets. Line coupling, character of the power lines, number of branch circuits, neighboring exposures, condition of insulators, and any design or operating condition that will produce transients, will have their influence on performance. Thus, while some installations may be reported as "entirely successful" and others as less satisfactory, the blame should not be too quickly placed on the apparatus used.

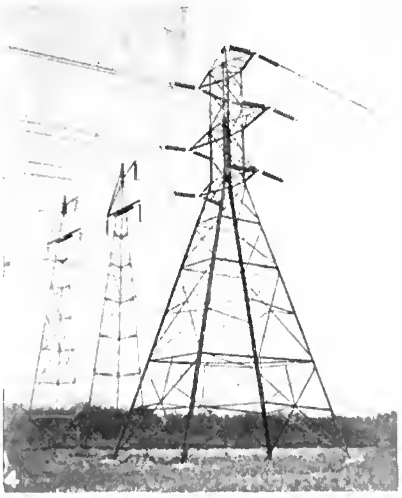
It was brought out in the description of the Baltimore-Holtwood installation in the ELECTRICAL WORLD for May 12 that the line coupling had to be changed several times before it was fairly satisfactory and is still not all that could be desired. Then, as pointed out in the discussion of the Duquesne Light Company's experience in the April 21 issue, there is the uncertainty of what determines the limits of the wave bands that are desirable for carrier-current communication. If resonant or impedance conditions are absorbing or choking the carrier current, the possible source of these obstacles must be known and fully understood in order to remove them. Another condition which arises in complicated transmission systems and affects communication is the cutting in or out of branch lines. Each line tap is known to have the effect of adding 15 or 20 miles to the length of transmission, and cables introduce still more complications. Harmonics inherent in the design of a system or disturbances caused by the charging of arresters or by "spitting" insulators, arcing grounds, switching and so forth are also factors which influence to no small degree the quality of carrier-current communication.

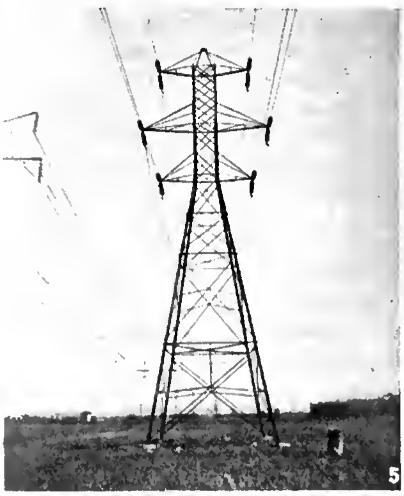
Despite all these difficulties, enough carrier-current installations are being made to afford a widespread field laboratory in which all the problems may be worked out if adequate records of performance and analyses are made. In seeking to overcome existing difficulties, however, it will be well to keep in mind the advisability of developing equipment for duplex operation. If this is not done, the user who is accustomed to the ordinary telephone may become confused in an emergency if he has to operate a button to allow two-way conversation. Another great advantage of wired telephones that must not be overlooked in developing the carrier-current telephone is that any patrolman can connect a portable instrument to the telephone line at any point. Some substitute arrangement that can be used with carrier-current telephony without too great expense must be worked out.

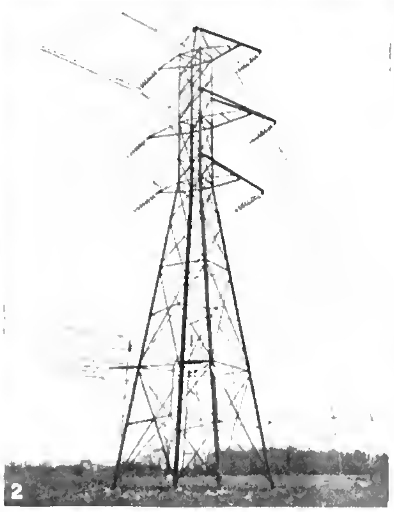
With full recognition of most of the difficulties and without any immediate prospects of profit in view, manufacturers are to be congratulated on their broad viewpoint in carrying on the work they are doing. They deserve every bit of support that operating companies can give them in solving the problems which still have to be faced before carrier-current telephony can be relied upon in emergencies. From the work that is now going on it is quite evident that operating companies foresee the possible benefit to themselves which will accrue from establishing a reliable means of communication in emergencies and that this support will be forthcoming without any pleading.

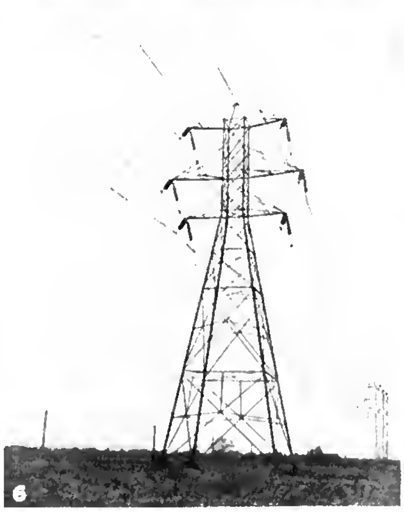
# Steel Towers for New Line

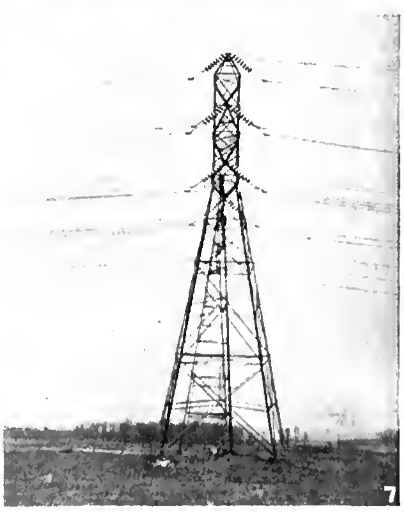


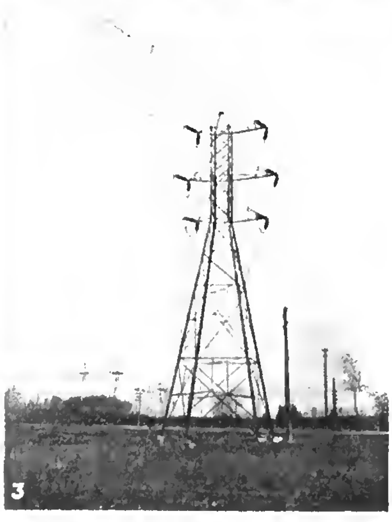


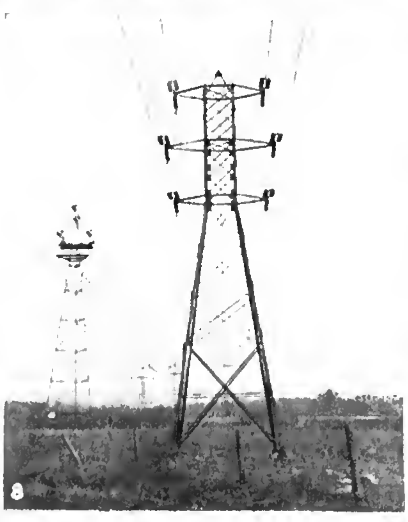


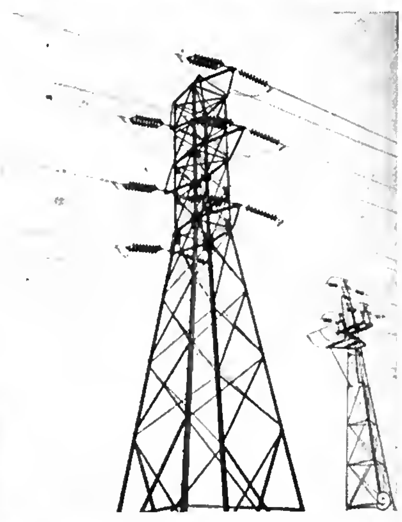












TYPICAL examples of the steel towers used on a 45-mile, 110,000-volt, double-circuit steel-tower line installed by the Niagara, Lockport & Ontario Power Company. A wind pressure of 13 lb. per sq.ft. on one and one-half times the projected area was assumed and a factor of safety of three was adopted. A double-galvanized extra-strength steel ground wire was used and a double-double insulator construction for crossings. Flexible towers are used for tangent lines and up to a 3-deg. angle. No. 1—Flexible tower type. No. 2—Thirty-degree angle tower. No. 3—Sixty-degree angle tower. Nos. 4 and 5—Dead-end towers. Nos. 6 and 7—Semi-anchor towers. Nos. 8 and 9—Railroad crossing towers.

# Double-Circuit Tower Construction

## Specifications, Design Details and Costs on New Steel-Tower Construction for 110,000-Volt Line—Foundation Arrangements and Methods for Installing Towers Discussed

By H. L. SHARP
*Engineering Department, Niagara, Lockport & Ontario Power Company*

STEEL-TOWER transmission lines offer opportunity for a great deal of engineering skill in design and installation. The type of structure is such that design formulas are difficult to use, and the variation in requirements for installation brought about by terrain conditions all add to the economic difficulty of satisfying requirements.

During the last year about 45 miles of new double-circuit steel-tower lines was erected in western New York as a part of the high-voltage system of the Niagara, Lockport & Ontario Power Company. This construction consists of two separate lines, one paralleling existing lines on right-of-way which the power company already owned and the other on an entirely new right-of-way which was recently purchased and on which no other lines existed. These lines were designed and built for 110,000-volt operation, but for the present they are being operated at 60,000 volts.

### Tower Types and Loading Specifications

The towers on these lines consist of several types. They were designed to sustain, with a factor of safety of three based on the ultimate strength, the loading given in Table I, together with their own weight and wind pressure of 13 lb. per square foot on one and one-half times the projected area of the steelwork.

The tower tops are provided with three cross-arms, so that the three conductors of one circuit are on one side of the tower and the three conductors of the other circuit on the opposite side of the tower. The top and bottom cross-arms are approximately 18 ft. long and the middle cross-arm is approximately 24 ft. long. Thus the wires on the middle cross-arm are 3 ft. beyond the vertical line through the other wires. The purpose of this arrangement is to reduce the chances for line trouble due to wire contacts with unequal ice loading on the various wires or other conditions which produce unequal sags in the wires.

These cross-arm lengths were determined by the insulation requirements. On all towers the clearance between the nearest live part and the steelwork of the tower, when the insulator string is in its normal position, is not less than 40 in. This refers to the distance between the end of the suspension clamp and the cross-arm or brace below the wire when the insulator string is vertical, or if there is an angle in the line so that the insulator string is deflected from the vertical, then it refers to the side of the tower or any other steelwork. When the suspension insulator string is momentarily deflected by wind to an angle of 45 deg. with the vertical, the clearance between nearest live parts and steelwork is not less than 36 in. The length of the insulator string from the surface which supports the insulator hook to the end of the cable clamp is 53 in.

On dead-end and 60-deg. angle towers the conductor loops between the strain clamps have a normal clearance of 44 in. to steelwork in all directions. This allows a slight swaying motion of the loop without reducing the clearance below the minimum specified value of 36 in. The 60-deg.-angle towers have cross-arms longer on one side of the tower than is the case on straight-line dead-end towers in order to maintain the loop clearances under all conditions.

The tower heights were determined by the condition that the distance from the surface of the ground to the lowest conductor should not be less than 25 ft. with maximum sag in the conductor. Thus the distance from the ground to the lowest cross-arm for level ground is 25 ft. plus maximum sag plus length of suspension insulator string. For strain towers the length of insulator string is not included. In order to maintain the desired clearances over uneven ground suitable extensions are provided for the various types of towers. These are added to the lower portion of the towers. Over highways the minimum clearance of 30 ft. is maintained.

TABLE I—LOADING FOR TOWER DESIGN

| | Power Wires | | | Ground Wire | | | Each Telephone Wire | | |
|---|---|---|---|---|---|---|---|---|---|
| Tower Type | Parallel-Line Load, Lb. | Cross-Line Load, Lb. | Vertical Load, Lb. | Parallel-Line Load, Lb. | Cross-Line Load, Lb | Vertical Load, Lb. | Parallel-Line Load, Lb | Cross-Line Load, Lb. | Vertical Load, Lb. |
| Flexible | 0 | 700 | 1,400 | 0 | 600 | 550 | 0 | 600 | 550 |
| Dead-end | *6,500 | 700 | 1,400 | 5 500 | 600 | 550 | 2,000 | 600 | 550 |
| Semi-anchor | †6,500 | 700 | 1,400 | †5,500 | 600 | 550 | 0 | 600 | 550 |
| 30-deg. angle | 0 | 700 | 1,400 | 0 | 600 | 550 | 0 | 600 | 550 |
| 60-deg. angla | *6,500 | 700 | 1,400 | 5,500 | 600 | 550 | 2,000 | 600 | 550 |

* Tower to austain unbalanced head pull of 6,500 lb. on all power wires.
† Semi-anchor tower is to austain the unbalanced head pull due to any two broken wires.

### Tower Types and Locations

On the right-of-way where the new line parallels the two existing 60,000-volt lines the new towers were erected opposite the towers on the old lines and at such a distance from the nearer line that the nearest adjacent wires are 15 ft. apart under normal conditions.

On the new right-of-way which was recently purchased in fee, there were no existing transmission lines to influence the location of the new towers. This right-of-way is 50 ft. wide and the towers are erected on a center line which is 20 ft. from one edge and 30 ft. from the other edge.

The location of the towers of the various types was determined as follows:

*Flexible Towers.*—Flexible towers are installed on straight portions of the line and on deflection angles up to 3 deg. On new right-of-way where no parallel line exists the normal spans are 600 ft. The anchors for

these towers consist of steel members buried in the earth without concrete. In order to provide a secure anchorage before the earth backfill has had time to become thoroughly compacted, this steelwork is installed according to Fig. 1, where the ground is suitable. This method provides a solid wall for the anchor legs to resist wind loads from either side and a considerable volume of undisturbed earth to resist uplift. The planks in the bottom of this footing help materially during the first year or two. The ground is not always such that straight walls can be cut or such that undercutting is possible. In that case the anchor is installed without undercutting the earth, and the earth is backfilled over the footing in the usual manner. In wet ground concrete is placed around the footing as shown in Fig. 2. Where solid rock is encountered the footings are installed according to Fig 3. If the rock is not perfectly solid, but has seams or is of a soft character, it is removed by blasting or otherwise so that a normal earth footing can be installed.

*Thirty-Degree-Angle Towers.*—These are square-base towers which are used with a single string of suspension insulators for each wire to support deflections in the line of 3 deg to 30 deg. Special cross-arms are used so that sufficient clearance is maintained between live parts and steelwork when the insulator strings are held in an oblique position due to the angle in the line. On angles up to 15 deg. earth footings are used, and on angles from 15 deg. to 30 deg. concrete footings are used.

*Sixty-Degree-Angle Towers.*—These are square-base towers which are used to support deflections in the line of 30 deg. to 60 deg. They serve the purpose of dead-end towers as well as angle towers. Insulators on these towers are used in the strain position. The cross-arms are unsymmetrical about the center line of the tower in order to maintain the necessary clearance between the conductor loop and the side of the tower. These towers have concrete footings.

*Dead-End Towers.*—Dead-end towers are erected approximately every two miles. They are suitable for dead-ending all wires under maximum loading conditions. Concrete foundations are used. In order to reduce the amount of concrete in the foundations necessary to sustain the overturning effect of the dead-end cables the bases of these towers were made 30 ft. long

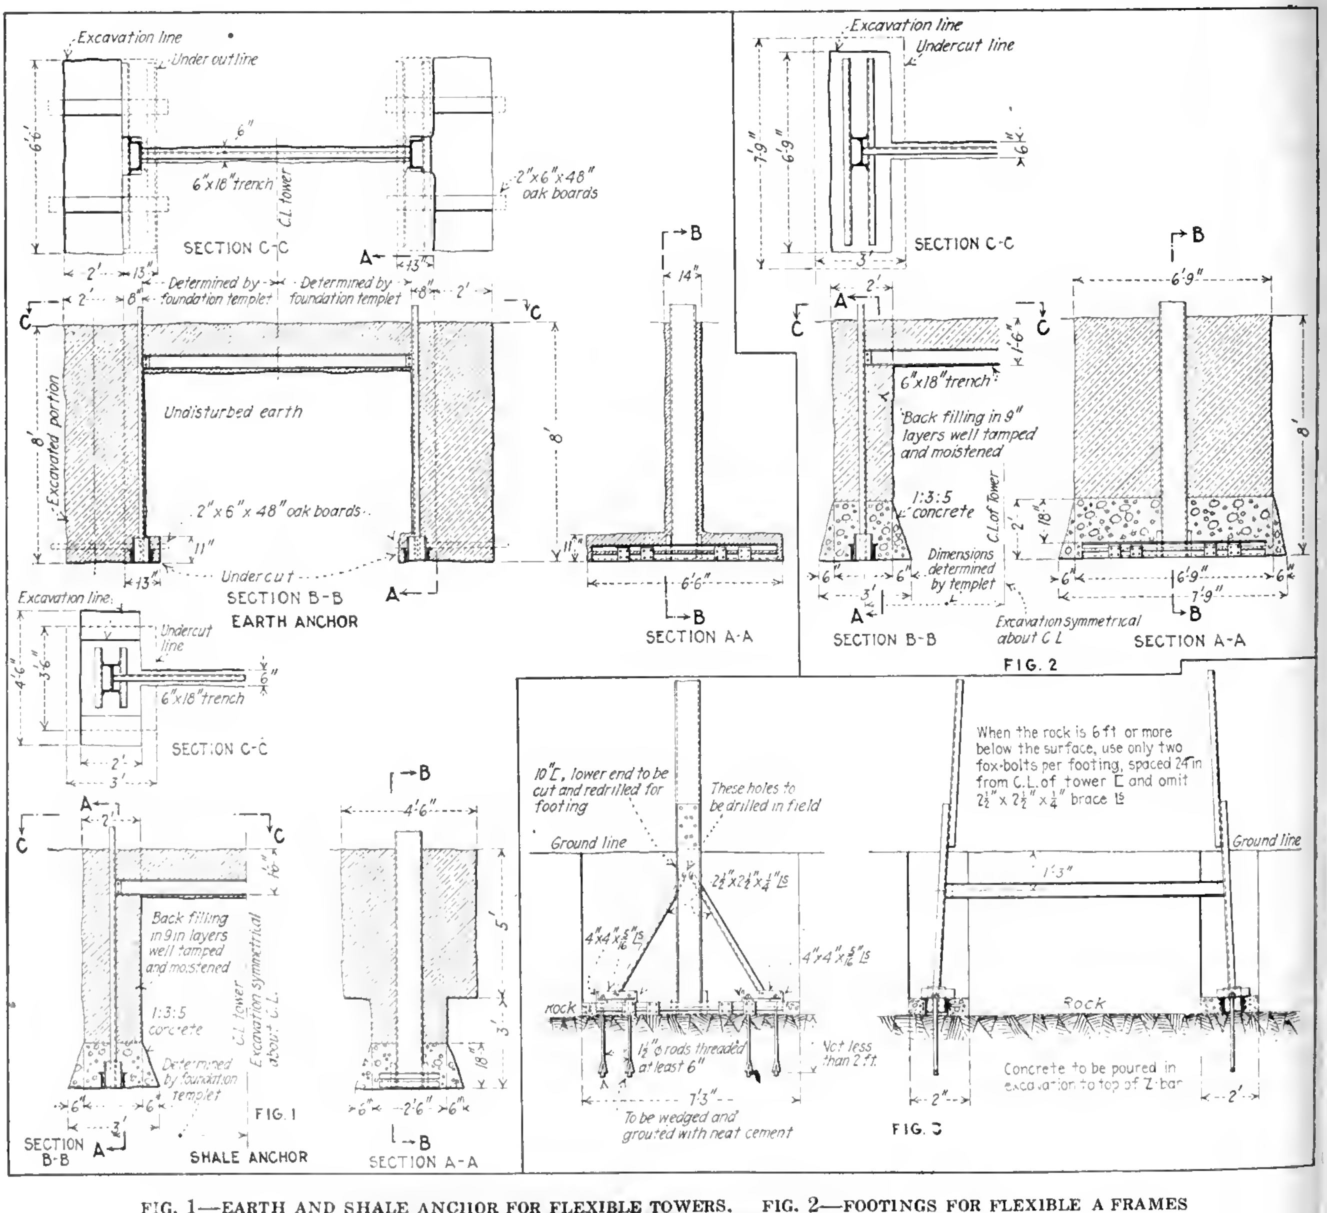


FIG. 1—EARTH AND SHALE ANCHOR FOR FLEXIBLE TOWERS. FIG. 2—FOOTINGS FOR FLEXIBLE A FRAMES IN WET GROUND. FIG. 3—ROCK FOOTINGS FOR FLEXIBLE TOWERS

in the direction of the line and 18 ft. wide across the line.

*Semi-Anchor Towers.*—Semi-anchor towers were installed so that two of them are at approximately equal intervals between dead-end towers; thus if dead-end towers are two miles apart a semi-anchor tower would be located two-thirds of a mile from each dead-end. Semi-anchor towers are designed to sustain the unbalanced load of any two broken wires. In good ground the footings are installed without concrete. If the ground is wet or otherwise unsuitable for earth footings concrete is added to give greater stability.

*Railroad Crossing Towers.*—Railroad crossing towers were of special design to meet the railroad companies' specifications. These towers are shown in the illustrations on page 1132.

The foundation members for all towers are held in place during installation by means of steel templets so designed as to hold the main members of the foundation in their proper relative positions.

### Insulators Are Standardized

On flexible, semi-anchor and 30-deg.-angle towers the insulator strings consist of seven units. On semi-anchor towers two insulator strings are used to support each conductor, the strings being arranged at 45 deg. to the vertical in the direction of the line. The conductor passes straight through as on a suspension tower and does not have a loop between clamps as on a dead-end tower. Long, flat steel links are used between the semi-anchor cable clamps and the insulators in order to place the conductors the same distance below the cross-arms as on the flexible towers. On dead-end and 60-deg.-angle towers the strain insulator strings consist of nine units. At railroad crossings double strings of nine units assembled in parallel, with steel yokes at each end, are used on the crossing spans.

TABLE 11—AVERAGE COSTS PER MILE FOR LABOR AND MATERIAL

*A*—Length of line, 14 5 miles; conductors, six 400,000-circ.mil copper; ground wire, one $\frac{1}{2}$-in. crucible steel; normal spans, 550 ft.

*B*—Length of line, 28.8 miles; conductors, six No. 4/0; A.C.S.R.; ground wire, one $\frac{3}{8}$-in. crucible steel; normal spans, 600 ft.

| | *A*—Cost per Mile | | | *B*—Cost per Mile | | |
|---|---|---|---|---|---|---|
| | Labor | Material | Total | Labor | Material | Total |
| Conductors, ground wire, insulators and hardware | $1,090 | $7,400 | $8,490 | $660 | $3,580 | $4,240 |
| Towers and foundations.. | 2,085 | 2,270 | 4,355 | 2,420 | 2,060 | 4,480 |
| Total................ | $3,175 | $9,670 | $12,845 | $3,080 | $5,640 | $8,720 |

### Use Galvanized Ground Wire

On one of the lines the conductors are 400,000-circ.mil medium-hard-drawn copper. They are strung with such sags that the maximum tension will be 6,000 lb. at 0 deg. F. with ice coating $\frac{1}{2}$ in. thick all around the cable and wind pressure of 8 lb. per square foot on the projected area of the ice-coated cable. Similarly the $\frac{1}{2}$-in. double-galvanized, high-strength crucible-steel ground wire will have a maximum tension of 5,500 lb. under the same conditions.

On the other line the conductors are No. 4/0 aluminum cables steel-reinforced. The maximum tension under conditions given above will be 4,000 lb. Similarly the $\frac{3}{8}$-in. double-galvanized, high-strength crucible-steel ground wire will have a maximum tension of 5,500 lb.

The ground wires are spliced by means of special copper McIntyre sleeves heavily tinned on the inside.

Some changes have been made in various features of tower designs and specifications for future lines of the same general type as described above. There will be under construction during the coming year about 175 miles of lines of this character. The principal modifications from the construction described consist in the use of structural-steel anchors for all towers except railroad-crossing towers and in the limitation of 5,000 lb. as maximum cable tension in the conductors instead of the 6,500 lb. in the original specifications.

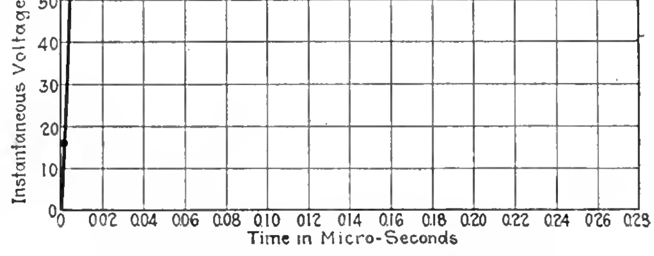
# Production of Lightning Voltage and Its Significance

## Impulse Generator Develops Voltage at the Rate of Fifty Million Million Volts per Second—Hazard of Omitting Shields

By F. W. Peek, Jr.
Consulting Engineer General Electric Company

In studying the effects of lightning on transmission lines and such apparatus as transformers, lightning arresters and so forth it is important to be able to produce lightning voltages in the laboratory closely approximating those occurring in practice.

An investigation of the lightning voltages induced on transmission lines has shown that during any storm many discharges take place on gaps set for lower voltages. The discharges become less and less frequent for the higher settings, and finally very few are found that exceed about 400 kv. However, higher voltages do occur occasionally. Another check on the voltage is the fact that insulator strings of seven or eight units rarely flash over during lightning storms. Lightning voltages or impulses are known to be of very steep wave front,



RATE AT WHICH THE VOLTAGE IS APPLIED BY IMPULSE GENERATOR

which has the effect of increasing the voltages across an insulator or other apparatus at the rate of millions of volts per second.

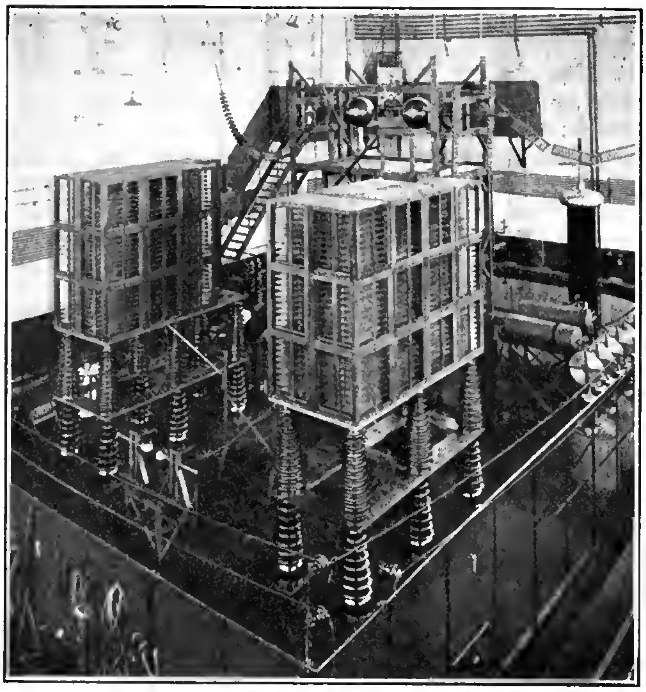
A few years ago a 200-kv. impulse or lightning generator was built to give lightning voltages of predetermined characteristics.* The time lag of various gaps was carefully measured and the term "impulse ratio"

*Peek, F. W., Jr., "The Effect of Transient Voltages on Dielectrics." *Transactions A. I. E. E.*, 1915, Vol. 34, page 1857.

resulted. This generator has been added to from time to time as higher exciting voltages have become available.

An increase to almost 750 kv. was made in 1916, while within the last year an increase to approximately two million volts has been made. It is not the intention to give details of the apparatus here, since these data as well as a description of the method of measuring voltage may be obtained from the paper mentioned above.

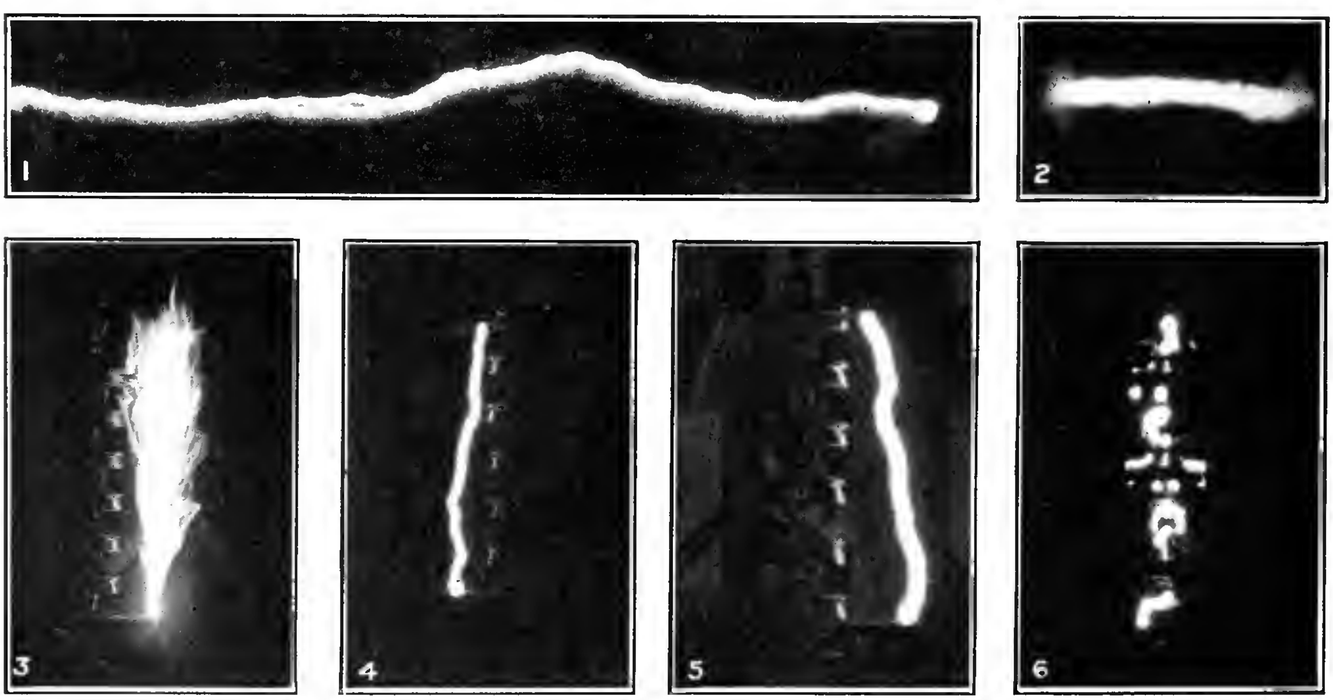
Briefly, the voltage is obtained by charging a large condenser to the desired voltage and discharging it through a known inductance and resistance. The result is a single lightning impulse of great power. In the lightning tests described in this article the voltages were applied at the rate of fifty million million volts per second. The power may be of the order of millions of kilowatts. The time of application is conveniently measured in micro-seconds (millionths of a second).



GENERAL CONSTRUCTION OF 2,000,000-VOLT IMPULSE GENERATOR

This type of discharge must not be confused with the high frequency obtained from an oscillator. In the lightning generator the discharge of energy is so rapid that the resultant spark is "explosive," and accompanied with a loud sharp report or crack.

Practical investigations similar to these illustrated are being carried on. Space will not permit details, but a few may be mentioned such as the propagation of lightning on transmission lines, protective value of lightning arresters, effect on insulations, value of ground wires, choke coils, etc. The generator is also of great value in theoretical work. It will permit the use of high energy discharges for studying steady and transient conditions on systems or equipment embodying new principles. Thus a new and exceedingly useful tool has been put at the disposal of the research worker which is bound to find ever-increasing applications of value.



TYPICAL DISCHARGES FROM THE IMPULSE GENERATOR. LOWER VIEWS SHOW FLASHOVERS ON INSULATORS

No. 1 — Million-and-a-half-volt lightning spark between needle points. Note that the discharge takes a zigzag path very similar to that of lightning.

No. 2—Lightning spark between spheres —the arc is about 3 in. in diameter; the current in the arc approximately 10,000 amp.

No. 3—Dry 60-cycle sparkover of a shielded insulator string. It is very important to know if lightning voltages will clear the string in the same way. Heretofore impulse voltages sufficiently high to spark over a string have not been available. Fig. 4 gives the desired information.

No. 4—1,200,000-volt stroke on dry shielded insulator string. The impulse goes to the shield and clears the string. This test was made in the dark. The photograph of the insulators was due to the spark lasting less than a millionth of a second. A still more important photograph is that shown in Fig. 5.

No. 5—1,200,000-volt stroke on shielded insulator string during heavy rain. The lightning spark clears the string in a heavy rain. The shield does not reduce the lightning sparkover voltages; neither does the rain. The display in the wet test is due to the reflection on the raindrops. Since the light producing this photograph lasted less than a millionth of a second, the illuminated drops appear stationary in space.

No. 6—Lightning sparkover (1,200,000 volts) of a dry non-shielded string. This is an undesirable condition since the skirts may be ripped off.

# Superpower Survey of Pacific Northwest

### Engineering Investigators Find that Existing Interconnected Power Systems Will, Through Natural Expansion, Prove Adequate for Many Years to the Needs of That Part of the Country

THE report of the engineers who, as representatives of various engineering organiations and chambers of commerce of Washington, Oregon and Idaho, undertook a two-year survey of electrical development in those states with reference to the desirability of a superpower system for the Pacific Northwest does not advocate taking any present steps in such a direction. As was stated in the ELECTRICAL WORLD of April 14, immediately after the report was made public, the engineers who made the survey are of the opinion that the vast and already interconnected systems of this great district will be sufficient, through natural expansion, to take care of future growth for many years to come without the need of developing a superpower system from which they would all alike derive energy.

The great water-power possibilities of the Pacific Northwest, says the report, and their relation to its general development can hardly be overestimated. In other parts of the United States the limitations of water-power development are being sensibly approached, because the cost of power from many undeveloped sources would be so great that it would not compare favorably with the cost of power produced by fuel. The Pacific Northwest is subject to no such limitation, and the abundance and reliability of its water powers is a vital factor in its commercial, agricultural and industrial expansion, which as yet has hardly begun.

In the early days of power generation, the report continues, interruption of service was a serious factor. With the growth of the power business this factor has become greatly minimized through interconnection of individual systems and the establishment of a network of transmission lines of sufficient capacity to perform emergency service in case of a local breakdown. It is these networks of lines of varied capacity which have permitted a division of the entire field considered into five groups. Within each group every reasonable precaution is being taken to avoid interruption of service. The assurance that now exists against such interruption would not be materially enhanced by the construction of superpower lines.

## EQUALITY OF EXISTING RATES AND CONDITIONS

General competitive conditions have brought reasonable equality in rates in the Pacific Northwest, the report continues. So far as any differences exist, they could not be eliminated by the construction of superpower lines, because the burden of their cost would fall upon the groups least favorably situated in this respect and would be reflected in the cost of the power delivered. A resultant lowering of rates in any one group, therefore, could be expected only if the difference in cost of group production were sufficiently great to exceed by a considerable amount the cost of providing superpower lines. This is not the case in any one instance. There is, however, an advantage in the exchange of power between groups in minor quantities which explains the construction now proceeding in various directions of group connections by ordinary transmission lines of moderate capacity such as do not come in the class of superpower lines.

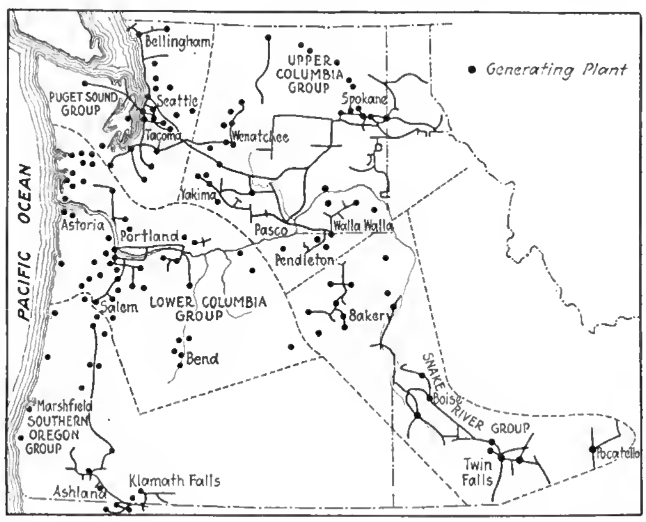


FIG. 1—GENERATING PLANTS AND TRANSMISSION SYSTEMS OF THE PACIFIC NORTHWEST AS OF MAY 1, 1923

A general benefit from superpower lines might be realized in all groups in case a seasonal excess of available hydro-electric power over market requirements in one or more groups coincided with a shortage in other groups, thus permitting wholesale seasonal interchange and resulting in an improved load factor for all. Climatic conditions in all groups so far as they control stream flow and seasonal excess over primary or all-year power are, however, in the main alike. There are some differences as to times when floods occur east and west of the Cascade Mountains, but these are differences of a minor character and are not such as to require or permit a large exchange of power were superpower lines built.

To those familiar with Northwestern power conditions it has long been apparent that the most valid

TABLE I—AVERAGE LOAD CONDITIONS BY GROUPS—1921

| Group | Average Load, Kw. | Peak Load, Kw. | Annual Load Factor, Per Cent |
|---|---|---|---|
| Puget Sound | 68,000 | 156,000 | 44 |
| Lower Columbia | 50,000 | 92,000 | 54 |
| Southern Oregon | 17,000 | 25,000 | 68 |
| Upper Columbia | 51,000 | 82,000 | 62 |
| Snake River | 24,000 | 37,000 | 65 |
| All groups | 210,000 | 392,000 | 54 |

TABLE II—TOTAL POWER GENERATED—1921

| Group | —Power Generated—Kilowatt-Hours— Steam | Hydro | Total | Steam Percentage Of Total |
|---|---|---|---|---|
| Puget Sound | 30,493,000 | 561,534,000 | 592,027,000 | 5.2 |
| Lower Columbia | 73,410,000 | 360,416,000 | 433,826,000 | 16.8 |
| Southern Oregon | 11,350,000 | 152,020,000 | 163,370,000 | 6.9 |
| Upper Columbia | 61,000 | 443,838,000 | 443,899,000 | .015 |
| Snake River | 1,260,000 | 202,018,000 | 203,278,000 | 1.6 |
| All groups | 116,574,000 | 1,719,826,000 | 1,836,400,000 | 6.3 |

reason for considering superpower connection at all must be sought in the variation throughout the year of power demands as compared with hydro-electric power supply, and it was this phase of the subject which received most careful consideration. The group load factors are, on the whole, favorable, and they can and will undoubtedly be improved by hydro-electric development within each group and by the use of storage. Superpower connection is not believed to be necessary for this purpose.

The question was considered whether in the future the number of possible power developments may not be reached in one group long before it is reached in other groups and whether at such a time a superpower connection may not be warranted or even essential to assure healthy expansion in all the groups. The investigators hold that water-power possibilities are so abundant and so evenly distributed over the entire territory, and that

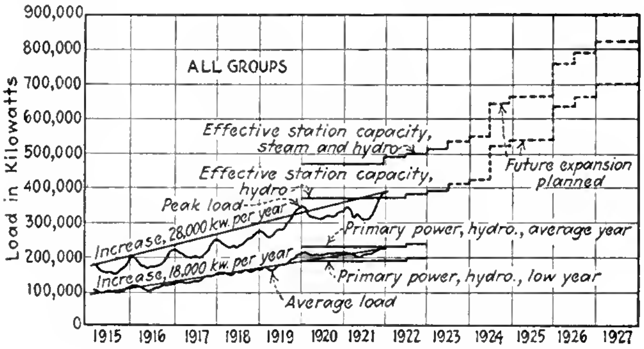

FIG. 2—DEVELOPMENT STEPS, PROVIDING FOR FUTURE EXPANSION, ARE DEFINITELY PLANNED FOR PACIFIC NORTHWEST

there is in each group such an enormous excess available that a group shortage of supply lies too far in the future to require consideration at the present time.

Fig. 2 gives the average load and the maximum load per month (one month) and the provisions planned to meet future demands of the entire Northwest. The terms which are used in Fig. 2 have the following significance:

"Effective station capacity" is the capacity of generation of the installed equipment in kilowatts. It is usually the capacity of the generators for a continuous run of one hour as limited by turbines or boilers, or the generators themselves, but not by water supply.

"Primary power, average year," is the effective station capacity of hydro-electric plants as limited by water supply during the average water year.

"Primary power, low year," is the effective station capacity of hydro-electric plants as limited by water supply during a low-water year.

The total average rate of generation in 1921 for all groups was 210,000 kw. and the peak load was 392,000 kw., giving an annual load factor of 54 per cent.

The committee's carefully studied conclusions are summarized in its report.

TABLE III—SUMMARY OF RATE OF GROWTH IN POWER DEMAND

| Group | Period | —Increase per Year, Kw.— Average Load | Peak Load |
|---|---|---|---|
| Puget Sound | 1915–1921 | 5,700 | 12,400 |
| Lower Columbia | 1915–1921 | 4,000 | 5,700 |
| Southern Oregon | 1915–1918 | 400 | 400 |
| Southern Oregon | 1919–1921 | 2,200 | 2,200 |
| Upper Columbia | 1915–1918 | 1,500 | 2,500 |
| Upper Columbia | 1919–1921 | 5,000 | 5,000 |
| Snake River | 1915–1921 | 2,500 | 2,800 |
| All groups | 1915–1921 | 18,000 | 28,000 |

"1. There is a healthy increase of power demand in all groups.

"2. Adequate provisions are under way in all groups to keep ahead of the estimated growing demand by the construction of hydro-electric plants and water storage. In the groups where steam power production is now an important element plans provide for reduction of the proportionate amount of power supplied by steam.

"3. The characteristics of the power load of each group are much the same, the maximum load occurring in the fall and winter, except in the Snake River group, where irrigation pumping produces a summer peak.

"4. The need of group connection by superpower lines is at present not sufficiently great to justify the expense even in the case of a line between the Snake River and Upper Columbia groups, where the advantage would be greatest.

"5. The power which can be economically exchanged between the several groups can be carried over ordinary transmission lines already built or likely to be built in the future.

"6. Existing networks of power systems will, through natural expansion, become more closely interconnected, but superpower lines are not likely to be needed unless economical development in one group reaches its limit while great excess of power exists in other groups. Such a condition is not likely to obtain for many years.

"7. Future large hydro-electric power development, in addition to that provided by existing systems normally expanding, is dependent upon the introduction of commercially feasible agricultural or industrial enterprises requiring large amounts of power.

"8. Such power development is of the highest importance to the Northwest. If wisely undertaken, it will come as a result of newly created markets, will tend to benefit other public utilities and stabilize rates, but will not in itself require superpower connection.

"9. Thirty-eight per cent of the water-power possibilities in the United States are situated in the area under discussion. The development work up to the present time has in the main been consistently carried along without unnecessary duplication. The expense of superpower construction, which must be incurred in other regions to save fuel or to equalize unbalanced power conditions, can be avoided for a long time in the Pacific Northwest. Superpower lines may, however, become of importance at an early date to carry power from our abundance to less favored regions to the south and east."

TABLE IV—PROBABLE EFFECTIVE STATION CAPACITY

| Group | Peak Load 1921 | Probable Future Effective Station Hydro and Steam Capacity in Thousands of Kilowatts at End of Year 1923 | 1924 | 1925 | 1926 | 1927 |
|---|---|---|---|---|---|---|
| Puget Sound | 156 | 192 | 248 | 248 | 332 | 332 |
| Lower Columbia | 92 | 115 | 154 | 154 | 179 | 204 |
| Southern Oregon | 25 | 33 | 33 | 43 | 45 | 45 |
| Upper Columbia | 82 | 135 | 143 | 143 | 156 | 156 |

# Economies of Complete Electrification in Large Buildings

## In Closing Down Private Plants Auxiliary Steam Equipment Should Be Electrified to Afford Maximum Saving to Customer—This May Exceed All Other Loads—Value of Exhaust Steam Overestimated

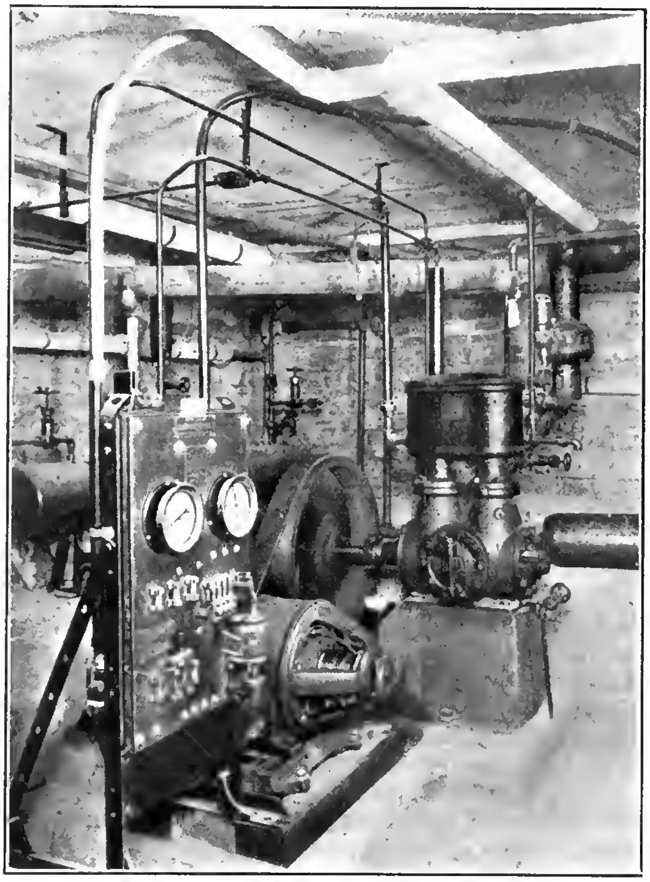
By W. H. WHITTON
*New York Edison Company*

A PRODUCTIVE field for extending the use of electricity, much to the advantage of both the supplying company and the consumer, exists in many large buildings which still have extensive equipments of steam apparatus, even though central-station service is used for other purposes. This condition is most commonly found where private generating plants have been superseded by purchased power, the substitution being unaccompanied, however, by any change to the attendant steam equipment.

It has been the experience of one large central-station company that a building which thus uses street service for its electrical requirements and at the same time produces steam for power to operate other equipment is run at needlessly great expense. The reason of this seems fairly obvious. Of the entire equipment of steam machinery found in the modern isolated plant, the engine-generators are usually by far the most efficient, and their discontinuance and the retention of other steam apparatus leaves in service the part of the equipment that not only is the most wasteful but that demands the greatest degree of attention.

The abandonment of generating units only, leaving other steam apparatus, such as elevators, pumps, compressors and auxiliary equipment, to be supplied from the building's boilers, usually has little effect, and sometimes none, on certain important items of expense, even though others are substantially reduced. Governed by local conditions, these reductions may or may not be sufficient to pay for the purchase of the electricity formerly generated locally, but it has been observed that the results are not nearly so satisfactory as where complete electrification is carried out, permitting wide-reaching economies in all directions. The fuel savings exceed those of the less complete change by much more than is represented merely by the former requirements of the steam machinery, the wastages in steam piping, traps and so forth in many plants with steam auxiliaries reaching as high as from 20 per cent to 25 per cent of the entire fuel consumption. The greater part of these wastages can by proper measures be eliminated.

From the central-station point of view, the complete electrification, as compared with the generator abandonment alone, presents very great advantages. It not only tends to add greatly to the satisfaction of the customer, but the income to the central station company is in many instances increased by a very material percentage, the exact amount, of course, depending on the extent of the former steam equipment. In hotels, where the changes from steam to electric drive may include elevators, house pumps, boiler-feed pumps, refrigerating machinery, brine pumps, air compressors, blowers, sump pumps, circulating pumps and kitchen machinery, the newly created electrical requirements may even exceed those formerly existing; that is, the consumption of electricity may be more than doubled.



ELECTRICALLY OPERATED REFRIGERATING MACHINE

TABLE I—CONSUMPTION OF ELECTRIFIED HOTEL EQUIPMENT AND ELECTRO-HYDRAULIC ELEVATORS

| | Kw.-Hr. One Year | Percentage of Total |
|---|---|---|
| Elevator pumps | 287,210 | 32.7 |
| House pumps | 66,925 | 7.7 |
| Boiler-feed pumps | 4,565 | .5 |
| Sump pumps | 1,344 | .2 |
| Refrigerating machine | 154,390 | 17.6 |
| Brine pumps | 56,206 | 6.4 |
| Light and miscellaneous | 306,400 | 34.9 |
| Total | 877,040 | 100.0 |

This is illustrated in Table I, which is an analysis of the electrical usages in a hotel in which the generators were shut down, electric pumps were installed to operate the hydraulic elevators, and electric machines substituted for the remainder of the steam apparatus.

TABLE II—CONSUMPTION OF ELECTRIFIED HOTEL EQUIPMENT AND STRAIGHT ELECTRIC ELEVATORS

| | Kw.-Hr. One Year | Percentage of Total |
|---|---|---|
| Elevator (passenger) | 10,456 | 4.5 |
| Elevator (passenger) | 11,933 | 5.2 |
| Elevator (freight) | 5,568 | 2.4 |
| House pumps | 2,878 | 1.3 |
| Refrigerating machine | 63,350 | 27.3 |
| Brine pump | 25,329 | 10.9 |
| Circulating pump | 4,246 | 1.8 |
| Light and miscellaneous | 107,990 | 46.6 |
| Total | 231,750 | 100.0 |

In this hotel the electrified apparatus consumes about 65 per cent of the total energy supplied and the original electrical equipment about 35 per cent. In other words, complete electrification rather than simple generator abandonment has almost tripled the value of the business to the central-station company, while a genuine service has been rendered to the building owner in securing to him better and more economical operating conditions.

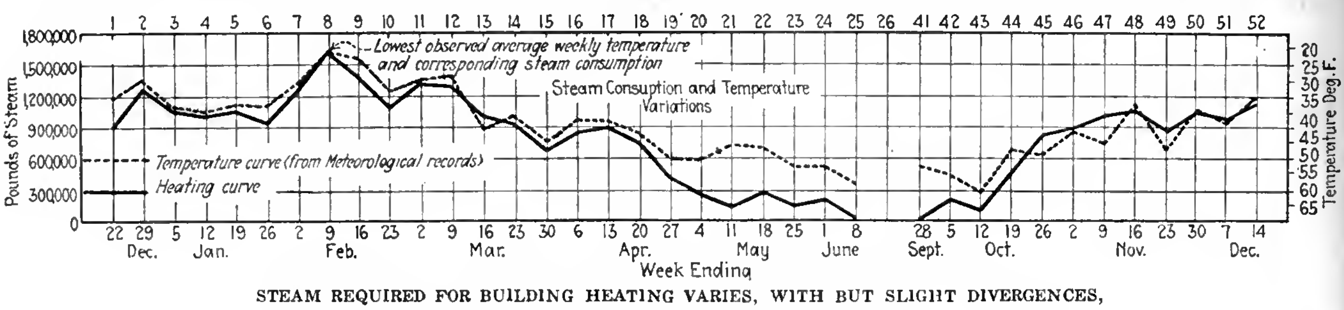
Table II shows values corresponding to those in Table I, the data, however, being obtained in a considerably smaller hotel with straight electric elevators. Owing to the fact that the elevators in this hotel were electric, the amount of new equipment and the energy consumed by it are relatively less than in the building shown in Table I. Of the total consumption, 41 per cent is used by the new equipment and 59 per cent by the old—a result which shows the importance of giving detailed attention to apparatus such as pumps and refrigerating machines, which, although less prominently in evidence than elevators, are in many cases of perhaps equal importance from both the property owner's and the central station's point of view—their electrification adding to the operating economy of the former and to the income of the latter.

Undoubtedly the installation of so much steam machinery in cities where the artificial heating of buildings is necessary during a substantial part of the year is due to the belief that this heat can be most economically furnished by the steam exhausted from the piston apparatus. The usefulness of exhaust steam for this purpose, as well as for water heating, has been greatly overestimated by many. Much of it is not available, and the rest can be utilized for building heating only during the winter months, and then but seldom to the full extent, as may be realized from observation of the wide range of temperatures occurring during the heating season. In the average building having a private plant the amount of exhaust steam made is fairly uniform from day to day, while the heating demands fluctuate widely, varying inversely as the outside temperature. This relation is shown clearly in the accompanying diagram, plotted from data obtained during the test of a large private plant in New York City.

Complete observations and measurements of the same plant, made over the period of an entire year, indicate how little, relatively, of the total steam produced could be utilized for building heating. The results are shown in Table III.

Here the exhaust steam used for heating was 39.3 per cent of the exhaust made, or 32 per cent of the total steam produced. Of the exhaust available for heating, only 52.3 per cent could be utilized for that purpose, the remainder being made at times when the supply exceeded the demand. Much of it was therefore wasted to the outer air, while a material percentage was lost in the foul drips, etc.

This test, during which the amount of steam distributed to each piece of apparatus was accurately measured during the year, will also serve to illustrate the relatively heavy steam requirements of the equipment other than the engines, a matter previously referred to. The values are shown in Table IV.



STEAM REQUIRED FOR BUILDING HEATING VARIES, WITH BUT SLIGHT DIVERGENCES, INVERSELY AS THE OUTSIDE TEMPERATURE

Analysis of these test results, which are fairly representative of a well-run plant, shows that the engines utilized about 44.4 per cent of the total steam produced and that 55.6 per cent was required for other equipment, for heating, or was wasted. The inadequacy of a policy which might simply contemplate the abandonment of the generating units, permitting the other apparatus to continue in operation, will be appreciated from these figures, which also convey some idea of the value of the field from the viewpoint of increased electrical sales.

The unsatisfactory results which may follow a partial change of the kind referred to, even though the steam equipment remaining in operation be small, may be realized from the example of a manufacturing building in which the abandonment of the generators was not accompanied by any readjustment of the other

TABLE III—UTILIZATION OF EXHAUST STEAM IN A PRIVATE PLANT AS DETERMINED BY ACTUAL TEST

| | | Lb. |
|---|---|---|
| Total steam produced | | 81,656,986 |
| Total exhaust steam made | | 69,116,887 |
| Exhaust steam not available: | | |
| Foul drip loss | 16,529,016 | |
| Condensed in house heater | 1,548,050 | |
| Drawn by ejectors | 252,014 | |
| Condensed by ice machine | 875,964 | |
| | | 19,205,044 |
| Exhaust steam available | | 49,911,843 |
| Exhaust to roof stack | | 23,852,060 |
| Exhaust steam used for heating | | 26,125,494 |
| Live steam used for heating | | 3,202,890 |
| Total steam used for heating | | 29,328,384 |

TABLE IV—DISTRIBUTION OF STEAM IN A PRIVATE PLANT AS DETERMINED BY ACTUAL TEST

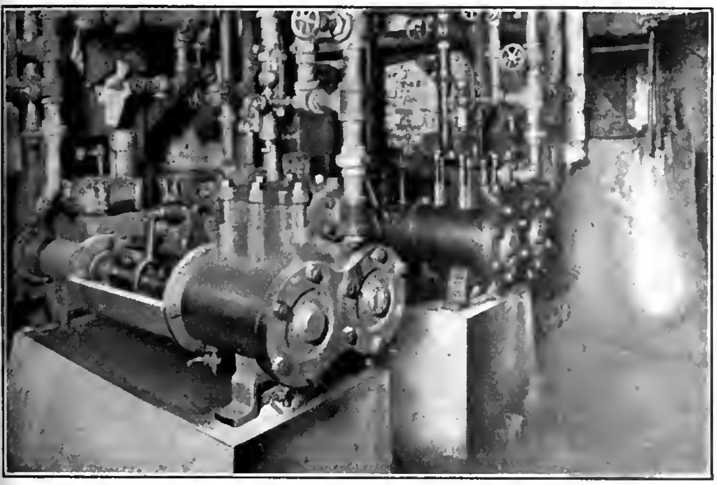
| Steam to | Lb. | Steam to | Lb. |
|---|---|---|---|
| Engines | 36,275,352 | Vacuum pumps | 2,375,711 |
| Auxiliary pumps | 8,416,425 | Ejectors | 1,225,421 |
| House pumps | 5,178,284 | House heater | 334,141 |
| Ice machine | 1,956,469 | Paul board | 266,936 |
| Elevator pumps | 12,509,868 | Clean drips | 8,736,125 |
| Return pumps | 1,179,357 | Reducing valves | 3,202,897 |
| Total steam made | | | 81,656,986 |

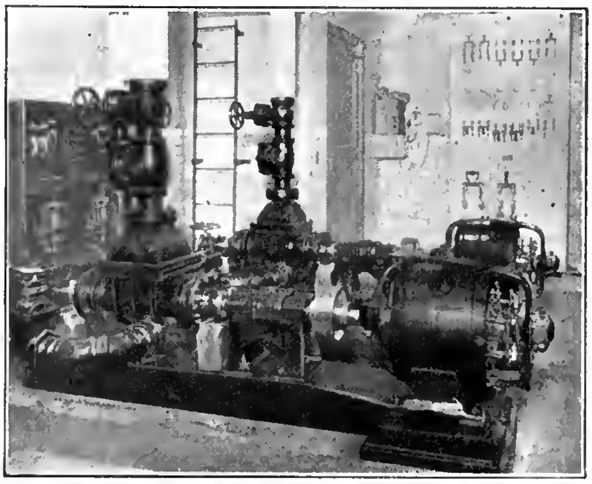
steam services. With the full plant in operation, the cost of producing light, power and heat had been about $33,000 yearly. With the generators closed down and electricity purchased, the cost was increased to about $35,000 yearly. A careful study of the causes of this unsatisfactory showing resulted in the substitution of several electric pumps for steam ones, increasing the electrical consumption by less than 4 per cent, and a complete rearrangement of the steam system which this change permitted. So extensive were the resultant economies that the operating costs were reduced to $23,000 yearly—a saving of $10,000 when compared with the plan of part central-station service and part locally produced power.

The results also call attention to the importance, if the full economies possible with central-station service are to be realized, of having expert steam engineering advice in planning the readjustment of the steam services. This is especially true in factories, where high-pressure steam may be required for industrial processes; in hotels, where cooking and perhaps laundry requirements are heavy, and in clubs and other buildings where similar conditions prevail. In the kitchen either gas or electricity, where the rate justifies it, can be substituted for steam, although in some instances it may be found advisable to adapt the kitchen equipment for operation with low-pressure steam. In the laundry the principal problem is the mangle; the smaller-sized machines can be successfully heated by gas, but for the larger sizes high-pressure steam seems a necessity.

Perhaps the best method of treatment is to install a small boiler, of the proper capacity and pressure, heated either by gas or coal as seems advisable. Under ordinary price conditions gas presents great advantages. Where the high-pressure steam requirements are sufficiently great, it may be found advisable, instead of installing a small new boiler, to devote one of the boilers formerly used for power purposes to the production of high-pressure steam, perhaps segregating the high-pressure system from the low-pressure system used for heating the building. A closed system of this kind reduces the heat losses to a minimum, eliminates many complications, and is both economical and convenient.

In the average building a complete steam and electrical changeover naturally involves a considerable outlay of money, one sufficiently great to explain the reluctance of many property owners to face the undertaking. The elevators usually constitute by far the largest item of expense — assuming that a complete change from hydraulic to electric power is made. In a building of substantial size having a number of elevators the investment may well run into thousands or even hundreds of thousands of dollars, a matter of very considerable concern to the property owner. Where the question of initial expenditure is an obstacle the installation of electric elevator pumps to replace those driven by steam may solve the problem. The cost of making the change is very much less, and while the consumption of energy may run from two to two and one-half times as much as with straight electric elevators, the saving in the fixed charges of interest, depreciation, and so forth may be sufficient not only to pay for the additional use of energy, but to compensate for the other items of expense which would be reduced if straight electric elevators were employed.





TYPICAL INSTALLATIONS OF STEAM PUMPS AND MOTOR-DRIVEN HOUSE PUMPS

There is probably no class of building equipment which suffers greater neglect and operates at poorer efficiency than steam pumps. The equipment shown was afterward superseded by an installation of motor-driven pumps.

Electric house pumps of 150-g.p.m. capacity, each operated by a 10-hp. motor. These units replaced the steam pumps in a large bank building when the private plant was abandoned and central station service installed.

The mileage and kilowatt-hour values obtained during elevator tests in three office buildings each with four hydraulic elevators the pumps for which were recently changed from steam to electric will serve to illustrate the requirements of electro-hydraulic equipment. The test results appear in Table V.

It may be of interest to compare with the foregoing the test results obtained on four typical elevators in one of the latest of New York's large office buildings. They appear in Table VI.

TABLE V—KILOWATT-HOURS PER CAR-MILE AS DETERMINED BY TESTS OF TWELVE ELECTRO-HYDRAULIC ELEVATORS

| | Building No. 1 | | | Building No. 2 | | | Building No. 3 | | |
|---|---|---|---|---|---|---|---|---|---|
| Week | Car-Miles | Kw.-Hr. | Kw.-Hr per Car-Mile | Car-Miles | Kw.-Hr. | Kw.-Hr. per Car-Mile | Car-Miles | Kw.-Hr. | Kw.-Hr. per Car-Mile |
| First. | 327.1 | 3,427 | 10.48 | 299.7 | 2,567 | 8.57 | 239.0 | 2,570 | 10.75 |
| Second. | 320.9 | 3,530 | 11.35 | 296.4 | 2,530 | 8.54 | 256.4 | 2,560 | 9.98 |

The rate of progress to be made in the further establishment of the principle of 100 per cent electrification will largely depend upon the efforts put forth in this direction by central-station interests. There are no other agencies equally concerned, nor any others so well situated to demonstrate the merits of all-electric machinery operating in connection with low-pressure steam systems.

At frequent intervals there should be something of interest to tell to every owner of a building in which such changes might advantageously be made. He should be made to comprehend the nature of the problem and its solution and to understand that the central station stands ready to undertake any necessary tests and studies of operating costs, to have specifications prepared for both electrical and steam changes, and to co-operate in every possible way in determining the best course to follow. If during the period of readjustment that inevitably follows the execution of changes as complete as those discussed the central-station company will keep in touch with the situation and be prepared to make such tests, observations and suggestions as will be of assistance in bringing about the most satisfactory operating conditions, the complete success of the venture will be assured.

## Increased Logging Speeds with Electric Donkey Engines

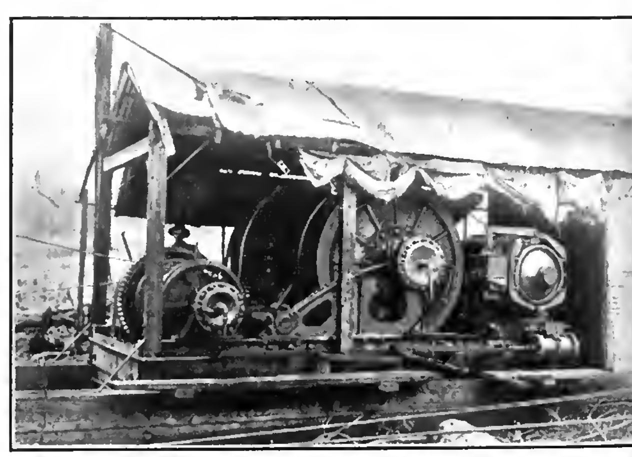
INCREASE in logging speed of 125 per cent and decrease in the cost of the operations have been accomplished together in the Pacific Northwest by the replacement of steam-driven donkey engines by electric motor-driven engines. In some instances—notably with the Snoqualmie Falls Lumber Company of Snoqualmie Falls, Wash.—combination yarding and loading units have been placed in operation and have proved far superior to steam-driven sets. Such a machine, having the yarder equipped with a 300-hp., 585-r.p.m., 550-volt motor and the loading machine equipped with two 75-hp., 580-r.p.m., 550-volt motors, has shown itself on test capable of handling 2,000,000 board feet of lumber per month.

In addition to the savings from the increased speed of operation, a great saving is made possible by doing away with the laying of pipes to supply water for the boilers of steam donkey engines. An additional saving in maintenance results from the elimination of the materials and labor for repairing the brickwork and tubes of the boilers.

TREES ARE USED IN YARDING OPERATIONS

Power for operating the electric units is distributed at 10,000 volts or 15,000 volts over inexpensive lines constructed with a realization of the temporary nature of the application. On the experience of the last few years' operating costs, electric drive can compete favorably with steam even with power costing $0.015 per kilowatt-hour and distributed as far as 7 to 10 miles through the woods.

Yarding and loading operations make up nearly 36 per cent of the total operating cost, neglecting stumpage, and these items are subdivided as shown in the table. This high proportion of the total expense indicates that the greatest economies in logging operations may be gained by electrification of the yarders and loaders.



ELECTRIC YARDERS MUST BE DESIGNED FOR RUGGED SERVICE

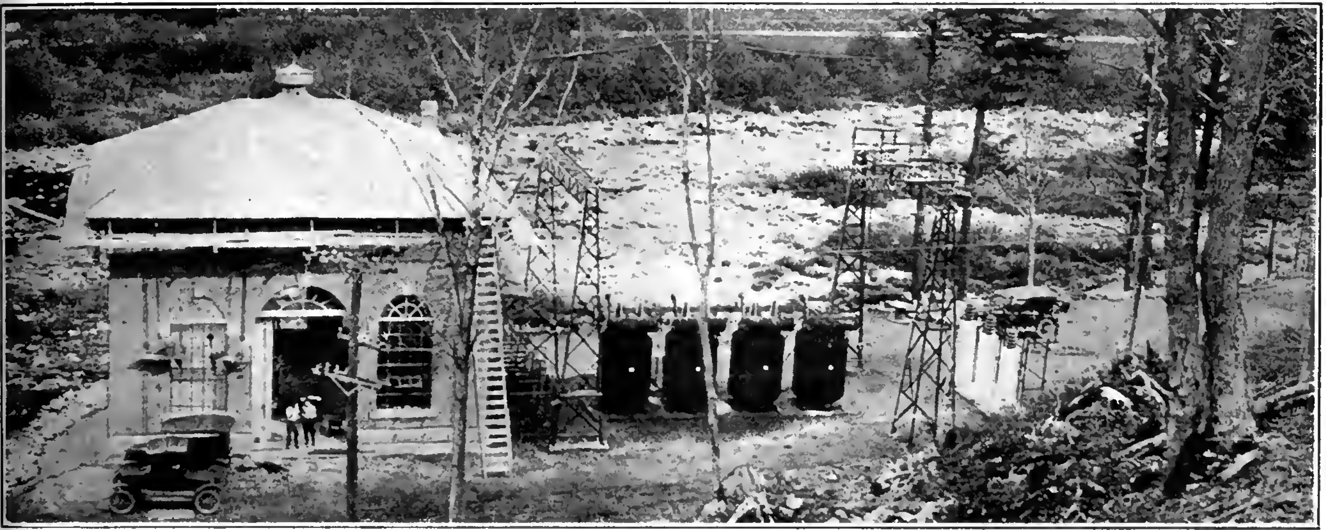
# Full-Automatic Hydro-Electric Station

## Adopted by New England Power Company for Relatively Inaccessible Site on Deerfield River—Tied in with Other Stations—Functioning Under Different Conditions Explained

By E. B. COLLINS
*Assistant Electrical Engineer New England Power Company*



LARGEST FULLY AUTOMATIC GENERATING STATION JUST COMPLETED

THE 5,000-kva. automatic hydro-electric generating station recently installed by the New England Power Company represents a considerable stride in the application of full automatic control. It is situated at Searsburg, Vt., near the headwaters of the Deerfield River in a mountainous, unsettled region which is practically inaccessible during the winter months. Under these circumstances the expense and difficulties involved in maintaining the necessary personnel for the operation of a manual station would have been considerable. Therefore, in order to take the fullest advantage of the natural power site, the operating company decided to install an automatically controlled station.

The station utilizes natural run-off supplemented by water stored about 9 miles up stream. Three miles above the station the water is diverted into a wood-stave pipe, which affords an average operating head of 210 ft. Energy from this plant is fed through a 15-mile, 66,000-volt line into the high-tension bus of another station on the system, where it is metered.

The equipment at the automatic station comprises one 5,000-kva., 2,300-volt, three-phase, 60-cycle vertical waterwheel generator, with directly connected exciter and automatic control equipment furnished by the General Electric Company. The generator is connected to an I. P. Morris waterwheel, which is controlled by a Woodward governor. The energy from the generator is stepped up by means of a 5,000-kva. bank of transformers to 66,000 volts and then transmitted to station No. 5 by means of the above line. The high-tension network is tied in at several points with other systems which serve a large part of New England. The control equipment is arranged for either full automatic or full manual control, the change-over being effected by a five-pole, double-throw knife switch installed on the control panel of the board.

The installation of this equipment was completed in March, 1922, but it so happened that before there was time fully to try out the automatic control, water conditions were such that it was necessary to start up the station at once. Consequently, the station commenced generation under manual operation and 4,800 kw. was placed upon the unit from the start and held there practically without change until tests on the automatic equipment could be made, which was not until the latter part of June. A better test of the abilities of a generating equipment to meet service demand could hardly be devised, and the results on this generating equipment were entirely satisfactory.

### FULL-AUTOMATIC FUNCTIONING

Since June the station has been operating under full-automatic control, carrying from one-fourth load to full load, depending on the varying water conditions which obtained on the river. As some of the features of the control and protective equipment are rather unusual, a description of the equipment and its operation should prove interesting. The power to operate the control devices is supplied by a control power transformer connected to the local 2,300-volt feeder, which is taken off the station bus and steps the energy down to 220 volts. The arrangement of the control circuits is shown on page 1144 and the operation is as follows:

With the connecting high-tension line alive from station No. 5 and the change-over switch No. 43 in the automatic position, the control power transformer No. 11 energizes the 220-volt control through the control power

4—Master control contactor.
3—Time delay stopping relay.
1—Master starting element.

switch No. 8. Sufficient oil pressure causes the oil-pressure relay No. 63 to remain open, leaving both steps of resistance in the circuit of the over-voltage relay No. 59, which remains closed if the voltage on the transmission line is not too high.

If the water level in the forebay is above a predetermined level, float switch No. 62 will also be closed. All other protective devices have their contacts in the normally closed position.

When the master control element No. 1 (in this case a time switch operating at a predetermined time) closes the coil of the master-control contactor, No. 4 is energized through the contacts of devices Nos. 43, 59, 3, 30x, 28x, 49, 12, 38 and 62. The closing of No. 4 energizes the governor solenoid No. 65, opening a pilot valve on the gate-operating mechanism, allowing the oil pressure to start opening the gate. At the same time the relief and inlet valves of the brake cylinders are operated by solenoids connected in multiple with No. 65, releasing the brake and allowing the generator to start. An auxiliary switch on No. 4 completes the circuit of a 12-volt battery through the coil of relay No. 28. This battery supplies power to the 12-volt direct-current control circuit, which is completed by the operation of either alternating-current overload relay No. 28 or differential overload relay No. 28a. This circuit supplies power to the trip coils on the generator oil circuit breaker No. 16.

### Bring Generator on Line as Induction Motor

When the generator comes up to about 95 per cent synchronous speed, synchronous-speed control switch No. 13 closes, energizing control current contactor No. 5, which thereupon closes. The closing of this contactor completes the circuit through the coil of auxiliary field relay No. 30x, which starts to close against a time delay through the contacts of field relay No. 30. The latter are closed until the generator field builds up. The closing of No. 5 also short-circuits No. 13, so that No. 5 is locked in against a momentary loss in speed. Contact is also made by No. 5 through underload relay No. 37 to the time-delay stopping relay No. 3.

Thus two conditions are guarded against, namely, failure of the field to build up and failure of the generator to take load. In the first case, if No. 30 does not open before No. 30x closes, the station will shut down, and in the second, if No. 3 opens, the coil circuit of No. 4 will be broken, de-energizing that contactor and shutting the station down. The first pole on contactor No. 5 completes the circuit through hesitating control relay No. 16x and the B switch on No. 16 to the 125-volt direct-current control bus, which is supplied by the generator exciter. Relay No. 16x closes, energizing control relay *CR*, which in turn energizes the coil of the generator oil circuit breaker No. 16, which thereupon closes.

The generator is now on the line without field and is acting as an induction motor.

### Synchronizing Generators

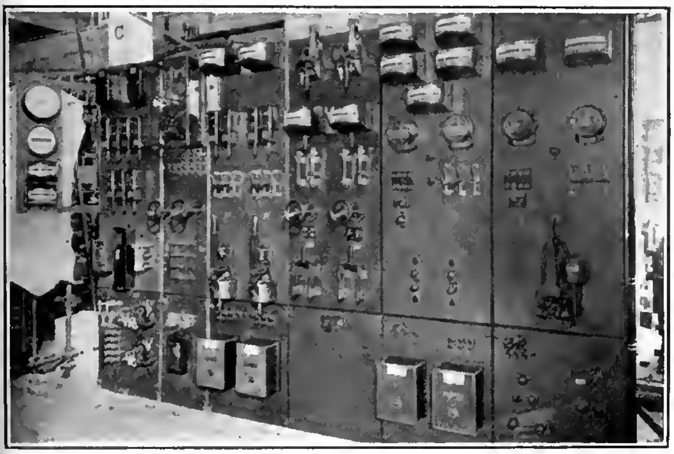
An A switch on No. 16 completes the circuit to hesitating control relay No. 44x. This energizes the coil of field circuit breaker No. 44, which closes, connecting the exciter to the generator field. This pulls the generator into synchronism, and it picks up load as the waterwheel gate continues to open to some predetermined gate opening controlled by means of a dial located on the governor. To the governor has been given a fairly drooping characteristic, so that the generator will not only carry approximately constant load but will do its share in holding the system to normal frequency.

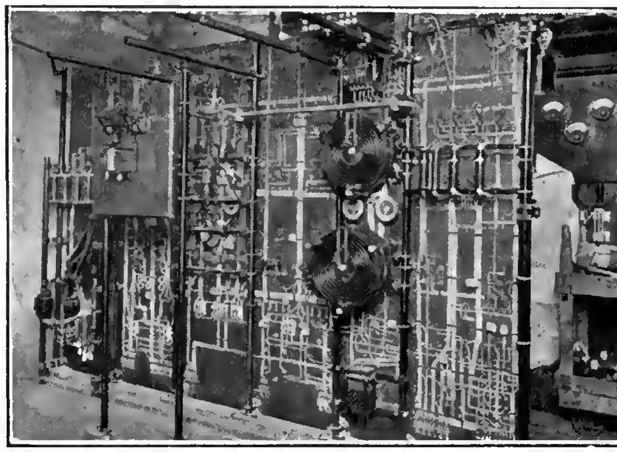
It may be of interest to know that the total time taken by the automatic starting sequence from the closing of the time switch No. 1 to the point where the station is on the line, carrying full load, is approximately 35 seconds. Furthermore, the phasing of the generator is accomplished so smoothly by the automatic equipment that it is not noticeable at station No. 5 unless one happens to be looking at the line ammeters.

### Shutting Down

Shutting down normally may be accomplished in three ways, namely, by the operation of the master element No. 1 at a predetermined time, by the operation of the float switch No. 62 when the water level falls below the predetermined minimum, and by the opening of the oil circuit breaker at station No. 5.

The sequences of operation in the various cases are as follows: When the time switch No. 1 opens its contacts, the coil circuit of No. 4 is broken and the contactor opens, de-energizing No. 65, which closes the gate. The brake-valve solenoids are also de-energized and returned to the position which allows the oil pressure to apply the brakes to the generator. Contactor No. 5 opens, and its B switch upon closing completes

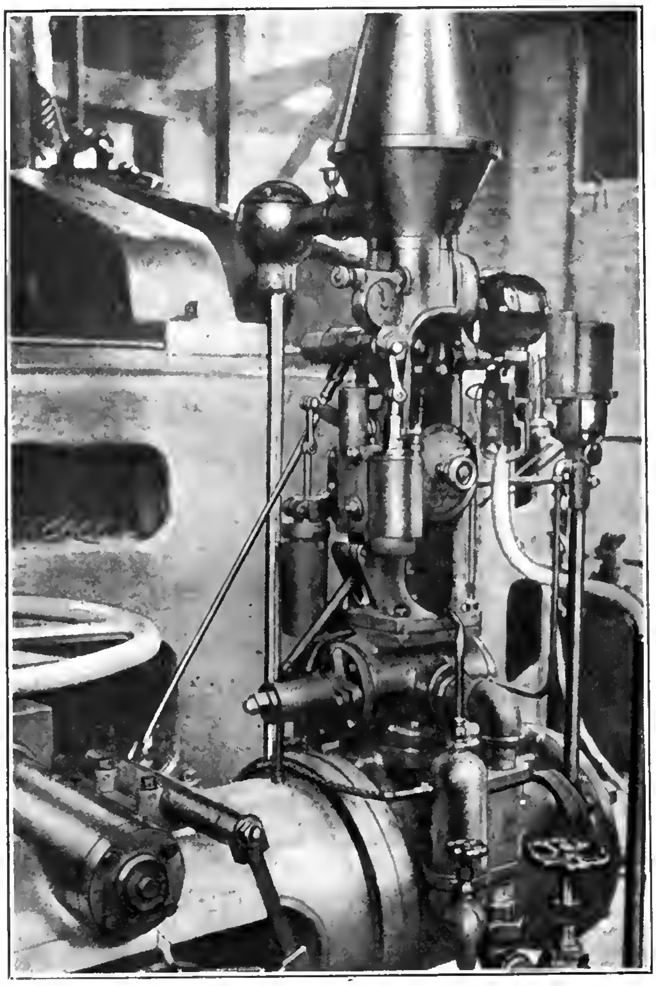




FRONT AND REAR OF RELAY, INSTRUMENT AND AUXILIARY PANELS OF AUTOMATIC HYDRO-ELECTRIC PLANT AT SEARSBURG, VT.

the 12-volt battery circuit through a hesitating control relay. This actuates the trip coil of the generator oil circuit breaker No. 16, which thereupon opens. When No. 16 opens, its B switch completes the battery circuit through the control relay and energizes the trip coil of field circuit breaker No. 44, which also opens, thus disconnecting the exciter from the generator field. The station is now shut down with all of the devices in the starting position, waiting for No. 1 to close again to restart.

In the second case, that of low-water level, the float



GOVERNOR OF 5,000-KVA., 2,300-VOLT, THREE-PHASE, 60-CYCLE WATERWHEEL GENERATOR

switch No. 62 opens, thus opening the master control circuit and shutting down the station as described in the preceding explanation.

In the third instance, when the oil circuit breaker at station No. 5 is open, the load on the automatic station is removed and underload relay No. 37 closes its contacts. This energizes stopping relay No. 3, which, after a time delay, opens the master control circuit, shutting down the machine as above. The generator cannot start again on the operation of the time switch until the oil circuit breaker at station No. 5 is closed, thus energizing the control power transformer in the automatic station.

As to the matter of protection, every possible contingency has been foreseen and guarded against. Besides the protective features already mentioned incidental to the features of operation, there are about thirteen additional possible causes of trouble for which provision has been made. Among them are overspeed, in which case the speed-limit switch No. 12 on the generator shaft operates, breaking the circuit of No. 4 and shutting the unit down; overload or short circuit in the windings of the generator, which causes differential relays No. 28a and No. 28 to operate, tripping out generator oil circuit breaker No. 16 and field circuit breaker No. 44; underload, which actuates underload relay No. 37, energizing No. 3 and thereby opening the master control switch, which shuts down the generator. In this case, if the time switch is still in the closed position when underload conditions have ceased and the power line is still energized from station No. 5, the unit will start up again immediately.

### GUARD AGAINST EVERY CONTINGENCY

Overheated bearings cause bearing temperature relay No. 38 to open its contacts at a bearing temperature of about 90 deg. C., thus shutting the unit down. On trouble of this nature the unit cannot be restarted without inspection. Low oil pressure in the governor causes oil pressure relay No. 63 to close, energizing No. 59, which breaks the coil circuit of No. 4, shutting down the machine. No. 59 must also be reset by hand before the unit can again be started.

Creeping of the wheel when the gate is closed is prevented by the operation of the gate valves as follows: When contactor No. 4 opens, it de-energizes governor solenoid No. 65 and also the relief and inlet valve solenoids. The relief valve closes immediately, but the inlet valve, which is connected mechanically to the gate, will not close until the gate is practically closed. When the gate has closed, the oil pressure in the cylinder builds up and applies the brakes, which prevents creeping of the wheel due to the small amount of water which leaks through the gates.

Delay and trouble from a serious breakdown of the directly connected exciter are taken care of by the presence of a spare exciter driven by an induction motor. In case either one fails, the other is immediately available.

The station is also equipped with a voltage regulator for regulating the station voltage. The regulator controls a short circuit around a rheostat in the field circuit of the exciter, so that if the voltage rises, the rheostat is cut into the circuit and reduces the exciter voltage and consequently the generator voltage. If the generator voltage is low, the rheostat is short-circuited, causing higher exciter voltage and consequent higher generator voltage. There is also provided with the voltage-regulating equipment an auxiliary overvoltage contactor and auxiliary exciter field rheostats.

It often happens in stations which are provided with directly connected exciters that in case of sudden loss in load on the generating equipment the speed momentarily reaches a high value, which also momentarily causes excessive exciter voltage and consequent high generator voltage. This rises to such a value that the normal voltage regulator is unable to take care of it. The above overvoltage contactor is arranged so that should this condition occur the auxiliary rheostat in the exciter field is cut in, thus dropping the exciter voltage to a point where the regulator can take care of it. Upon generator and exciter speed coming down to normal, this auxiliary field rheostat is again short-cir-

cuited by means of the contactor, and the regulator again functions as under normal conditions.

Since the station has been in automatic operation, there has been very little trouble experienced with the automatic equipment. Regular inspection of the apparatus is maintained, and care is exercised that contacts shall be kept clean. The station is in a section of the country where lightning conditions are rather severe, and the connecting high-tension line has tripped out numerous times owing to lightning disturbances. The generating equipment has in every case promptly shut down and remained down until the line was again energized from station No. 5, whereupon the equipment has promptly started up and again come on the line and carried load.

Owing to the fact that the amount of oil required for the operation of the brakes is rather large in comparison with the oil system available at the station, it was decided to operate the brakes by means of water, which is supplied at penstock pressure by means of a small valve and through proper strainers. This seems to work out very satisfactorily and results in considerable reduction in the duty imposed upon the governor oil system.

## Bureau of Mines Comment on Powdered Fuel

MANUFACTURERS and operators of the larger coal-fired furnaces cannot afford to disregard the possible advantages of pulverizing their coal before burning it, John Blizard, fuel engineer of the Department of the Interior, says in Bulletin 217, just issued by the Bureau of Mines. The bulletin, which contains information regarding the preparation, transportation and combustion of powdered coal, is published through the courtesy of the Canadian Department of Mines, for which the bulletin was originally prepared. He says in part: "Since the coal has to be pulverized, it is generally better to purchase slack coal, which is usually cheaper and costs less to pulverize. The requisite composition of the coal depends upon many factors. Practically all coals from lignite to anthracite, and even coke breeze, have been pulverized and burned. But anthracite and coke breeze require more energy to pulverize them than softer coals, and low-volatile coals are difficult to ignite and must be burned in specially designed furnaces.

"One of the principal difficulties in burning powdered coal lies in the disposition of the ash, and for this reason it is desirable also to use a coal which contains little ash and that melts at a comparatively high temperature.

"The power used to pulverize and convey similar coals to the burner is approximately proportional to the weight of the coal pulverized, and it is clear that the pulverizing and conveying costs will therefore be greater per heat unit delivered the lower the calorific value of the coal.

"On the whole, powdered-coal plants cannot be said to be clean. There are fairly clean powdered-coal plants, but generally, though not universally, a plant using powdered coal is dirtier than a grate-fired plant. Powdered coal is better adapted for firing stationary water-tube boilers than other boilers. With these boilers furnaces of sufficient size and of the correct shape may be constructed, and the gases pass through no tubes wherein ash may settle to obstruct the draft and shield the heating surface.

"The possibility of a dangerous fire or explosion in a well-designed, well-managed powdered-coal plant is remote and should not influence the prospective user of powdered coal against installing it."

## Arc Welding as a Manufacturing Asset

### Structural Steel Can Often Be Substituted for Castings at a Material Saving — Riveting of Thin Metal Parts May Be Avoided

By J. F. Lincoln
Vice-President the Lincoln Electric Company

THE use of arc welding is usually limited, in the minds of the people who are not personally in touch with its application, to the repairing of broken parts or to the building up of friction surfaces that have been worn down. The average man remembers that the engines of the German ships in the harbors of the United States at the time of the late war were broken and left by the Germans as a total loss. He also remembers that by a new process of arc welding these engines were repaired in a few days and the ships put into operation, much to the chagrin of the Germans and much to the credit of arc welding. While this feat had a great effect in fixing in the minds of most people that arc welding is a wonderful thing with which to fix engines on German ships, it is doubtful if repair work is even a considerable part of its usefulness to mankind.

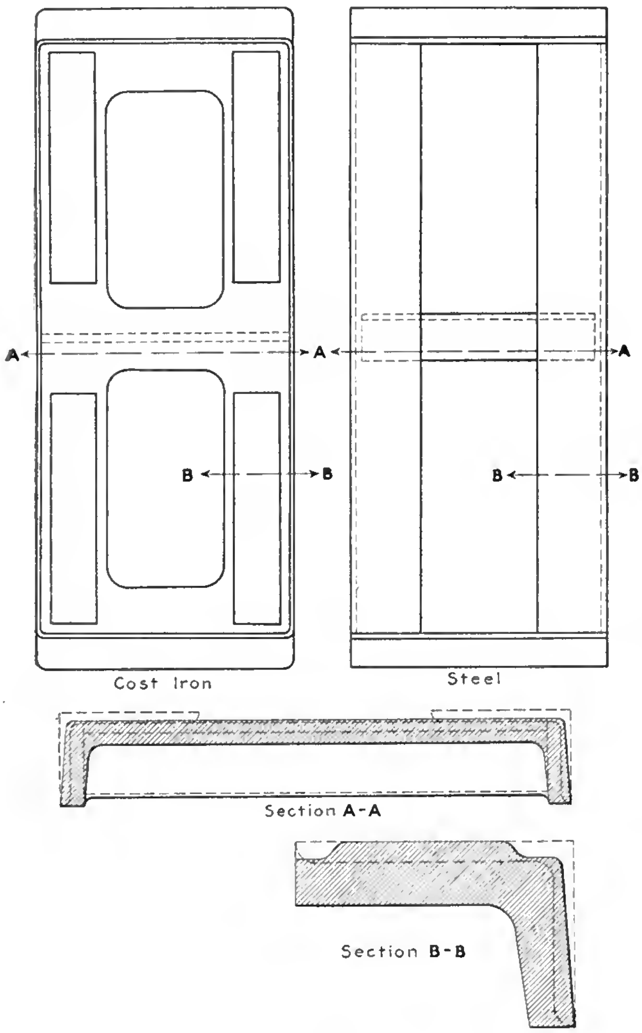
#### Arc Welding a Manufacturing Asset

Arc welding can be of the greatest service in the manufacture of parts which are usually made of cast iron. Its use there is not for repairing, but in the actual manufacture of these parts from standard structural steel shapes. The importance of this statement rests upon the fact that the cost of cast iron per pound compared with standard steel shapes is as three to one.

The strength of steel is as five to one compared with cast iron. This means that a part which is usually made from cast iron will if made of steel be equally strong at a cost of no more than one-fifteenth of the cost of the same piece if made of cast iron. This ratio, of course, will not always hold, because many other factors, such as appearance and inability to get the exact standard structural shape that is needed for the thing to be made, come into the problem. It does, however, show what the absolute cost ratio between the use of the two materials is when the tensile strength and cost only are considered. The cost of welding must be added to the cost indicated for steel, since the cost for cast iron on which this statement is based is for a completely molded casting, while the steel cost does not include welding. However, the welding cost is usually a small proportion of the steel cost and will vary according to the part to be made. Here lies the great opportunity of the designing engineer. He should be just as fully acquainted with the possibilities of arc welding as he is with the strength and possibilities of riveting.

The drawing shows details not because it is an extreme

case of the difference in cost between the two methods of making the same object, but because it is a part that all interested readers have seen and because the savings shown have been actually made. It is therefore a graphic illustration of what can be accomplished. The part shown is a motor-generator set base made by the two different methods. The one is a base made of structural steel parts and the other of cast iron.



EXAMPLE OF HOW STRUCTURAL SHAPES WELDED TOGETHER CAN REPLACE CASTINGS

The illustration at the left is a cast-iron base. That at the right is made of structural steel welded. Comparative cost:

| Cast-iron, weight 188 lb. | | Structural steel, weight 85 lb. | |
|---|---|---|---|
| Cost of casting | $13.16 | Cost of steel | $1.91 |
| Cost of machining | 2.50 | Cost of welding | .90 |
| Total | $15.66 | Total | $2.81 |

The resistance to bending is equal and the steel base is unbreakable. There is also the advantage with the steel base that no machining is necessary and the saving will more than make up for the cost of welding.

Other examples of this type that can be mentioned are:

1. Switch tanks for oil switches and compensators. Here the steel has an added advantage of being impervious to oil while cast iron is not.

2. The manufacture of motor-base rails. Here a drawn piece of channel section is made complete by welding on the tang which holds the adjusting screw.

3. The manufacture of motor and generator frames for automobile starting and lighting generators. Flat stock bent into a ring and welded will be enormously cheaper than pipe or castings such as are usually used. This also applies to frames for larger direct-current and alternating-current motors.

4. The manufacture of punch-press and drawing-press frames. Not only will the cost be not more than 10 per cent as great as for cast iron but broken frames are impossible. This would be a great boon to all users of such machines. In all these cases the saving is at least one-half of the cost of the same parts made of cast iron.

These examples can be multiplied by hundreds, and in all cases savings can be shown which range from 10 to 98 per cent of the cost of the same part made from cast iron.

### Chance for Increased Use

When the process is fully understood by the designing engineer, he will increase again the known applications as a result of his own experience.

At present the application of the arc is made usually to parts which were designed to be riveted or brazed. This often puts arc welding at a great disadvantage as the preparation of the part is entirely different for arc welding from what it is for riveting. Even in such cases the application of the arc has made great savings.

An example that may be cited is this: The usual range boiler, made by millions and used in almost every modern home for water heating, has, by custom, been riveted ever since it was first made. Rivets on thin metal do not make a job that is tight so the tank is galvanized after riveting. The galvanizing helps to fill up the gaps left by the rivets. After a time, however, the galvanizing disappears, leaks start and a new tank is necessary. To put off the evil day of leaks the manufacturer now rivets as of old and then welds the edges down. This eliminates the leaks on the edges but does not stop the leaks around the rivets. It is a better job than before because it stops up half of the places where leaks can occur. Sometime some manufacturer will weld the seams and forget to use rivets and the problem will be solved, saving about 80 per cent of the labor cost of doing the job and producing a boiler twice as strong.

### A Few Characteristics

The designer can rely on the following characteristics of a properly arc-welded joint:

1. One hundred per cent strength compared with the sheets welded.

2. A fraction of the cost compared with riveting, brazing or gas welding.

3. Automatic apparatus for welding duplicate work.

4. Possibilities of saving a large part of the present cost of making his product if arc welding is scientifically applied.

Arc welding in many ways is new, although the process itself is nearly as old as the discovery of the electric machine. Its progress is a revelation even to those closest to it, and new uses and methods are discovered almost daily. The engineer should look at the process as one which has wide application and one which should be first considered when the manufacture of any steel product is contemplated. Its use is tremendously more important than riveting, and its results can be almost universally depended on to be much cheaper, stronger and more satisfactory.

A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute

## Dr. Hutchinson Disputes Efficiency Percentage Given for Oil-Burning Locomotive

*To the Editors of the* ELECTRICAL WORLD:

The report in your issue of May 5 on the discussion of A. H. Babcock's paper on "Some Fuel Determinations on the Southern Pacific System," presented at the Pittsburgh meeting of the American Institute of Electrical Engineers, seems to call for some comment, particularly with reference to the report of my discussion.

The principal object of my discussion was to point out that the interpretation given by Mr. Babcock of his own tests is misleading. His statement that the "overall efficiency" is 5.57 per cent is not borne out by the tests themselves. This efficiency was obtained by considering only the oil used when drawbar pull was positive and is measured at the rim of the drivers, i.e., includes the work done in moving the locomotive itself.

My viewpoint is that this is entirely misleading—that all oil used should be included, and that efficiency should be measured at the drawbar for the same trailing load. Under these conditions the efficiency becomes 3.12 per cent—very different from 5.57 per cent. This, the most significant point of my discussion, is not referred to in your report, which, in effect, spreads abroad the statement that the efficiency found was 5.57 per cent.

It would have been interesting to discuss the general matter of railroad electrification as Mr. Davis seems to have done, but Mr. Babcock's paper did not touch upon this in any way, and I therefore confined myself to the subject of the paper.

CARY T. HUTCHINSON.

New York, N. Y.

## Reactive Kva., Prunes and Poems

*To the Editors of the* ELECTRICAL WORLD:

In regard to R. C. Fryer's letter in the ELECTRICAL WORLD for April 28 concerning the justice of billing power consumers for reactive kva. or reactive kva.-hours, I am inclined to agree with Mr. Fryer that it would be difficult to justify any rate applied to something delivered and returned 120 times per second, and which neither the central station nor the customer wants or can use.

If a grocer sells and delivers to a customer a pound of prunes, he should be entitled to the cost of the prunes delivered through his regular channels. If the customer orders the prunes sent up accompanied by an original poem on prunes, it is quite likely that the grocer would expect the customer to pay for the poem.

Reactive kva.-hours are fully as harmonious and beautiful as a poem, of a little less economic value, and their cost of production and delivery is indeterminate. They resemble the active kva.-hours very much as the poem resembles the prunes. On the other hand, it is true that in many localities cost of electric service is practically independent of the amount of energy used but is almost wholly dependent on demand, not in kw. but in kva. These considerations lead one to preserve a mind open to reason and conviction and to hesitate before condemning categorically the idea of charging for prunes on a conversion ratio of liters to poetic meters, or for electric service on a basis of reactive kva. In the early days central stations charged on the basis of lamps; later the charge was for ampere-hours. Here in Connecticut at the present time electric service is paid for on the basis of the number of square feet floor area, and consumers appear to be happy about it; moreover, in the main it is equitable.

Information on all points controlling the cost of electric service should be secured by the central-station company, and this includes, among other things, energy consumption and power factor. At least two instruments are necessary to obtain this information, and if active and reactive component watt-hour meters are used, other information may be derived, including kva.-hours. Local conditions will determine the most convenient and most equitable measurements to use.

H. J. BLAKESLEE,
Treasurer.

The States Company,
Hartford, Conn.

## The Central Station and Street Lighting

*To the Editors of the* ELECTRICAL WORLD:

The ELECTRICAL WORLD in its campaign for better street lighting is rendering a service to the industry worthy of the highest commendation. The editorial in the issue of Feb. 24 on "How a City Gains by Better Street Lighting" sums up the whole situation in a nutshell, and the last paragraph, "What does the operating company gain?" is of vital interest to the electric light and power companies.

Many of the operating companies have apparently failed to recognize that the rapid development in street-lighting practice during the past few years has created new conditions and that, in the interest of the industry, the central-station companies must take their place in their respective territories as leaders in the promotion of improved street lighting.

While it is true that, in spite of large advances in the cost of materials and labor, street-lighting rates have remained practically constant and that the street-lighting load has not generally been an attractive one for the central stations, there is no reason why the central stations should not undertake the sale of better street lighting on a business basis, charging a rate which would make it a profitable part of their service, interesting to the city as an economical improvement contributing to its safety and progress. Street lighting should not be looked upon as a political football, threatening municipal ownership. It is a civic improvement, affording the central station an opportunity for meeting municipal officials on a common ground, and should be the means of developing cordial relations between the central stations and the municipality.

The manufacturers of street-lighting equipment are doing their part in educating the public by extensive national advertising campaigns and by missionary work through trained street-lighting experts. Municipal officials are also showing their interest by giving a prominent place to discussions on street lighting at meetings of municipal associations and societies.

The real development in the street-lighting business will only come when the central stations themselves advocate improvements instead of holding aloof and awaiting the results of the efforts of the manufacturers of lighting equipment. If the municipal demand and the central-station ability can be co-ordinated, there is before us a tremendous prospect for more and better street lighting.

# Central Station and Industrial Practice

**Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants**

## Automatic Switch-Reclosing Apparatus

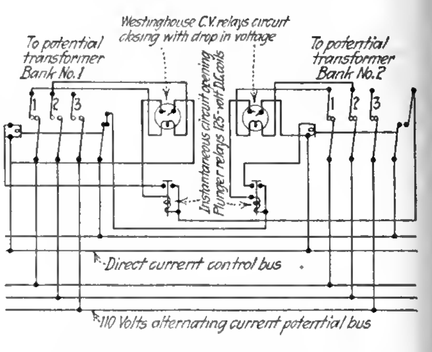
**Developed by Alabama Power Company and Successfully Used in Several of Its Substations—Has Extensive Application to All Classes of Apparatus**

FOR the automatic reclosing of switches which are opened because of trouble on the circuit or in apparatus connected thereto the Alabama Power Company has developed the apparatus described and illustrated herewith. At the Vida substation this reclosing equipment has been successfully used for more than a year to operate a 44,000-volt, 300-amp. G. E. "KO-26" oil switch. This station is operated by one man whose additional duties involve two days per week spent in patrol of lines in the district. The switch operated by the reclosing device controls an important circuit supplying Selma and other large customers. Continuity of service is of the utmost importance, and if during lightning storms, when the operator may be out on patrol or away from the station getting supplies, or during the night, when he may be asleep, the switch opens automatically because of flashovers or other troubles on the line, the reclosing device will, after a period of one minute, reclose the line switch. If trouble still exists, the switch will immediately open automatically the second time and close once more after a period of one minute. A continued fault will cause the switch to open again automatically, after which it will become inoperative until reset at some time by the operator after the trouble has been cleared.

The energy for operating the reclosing device may be either direct-current or alternating-current, and only 300 watts at the maximum is required. At Vida the source of supply is secured from a 44,000-volt potential transformer used to carry a few lamps about the station.

During the lightning season of last year the oil breaker at Vida automatically opened a number of times, and in each instance the reclosing device closed the breaker after the one-minute period. Recently line failures caused short circuits which remained until troubles were cleared on patrol, and the device reclosed the oil breaker twice and then became inoperative until the line foreman telephoned the Vida operator to test the circuit.

At the Dora substation four 2,300-volt feeder switches are connected for operation from a single reclosing device. Each switch has an individual contact switch closing the

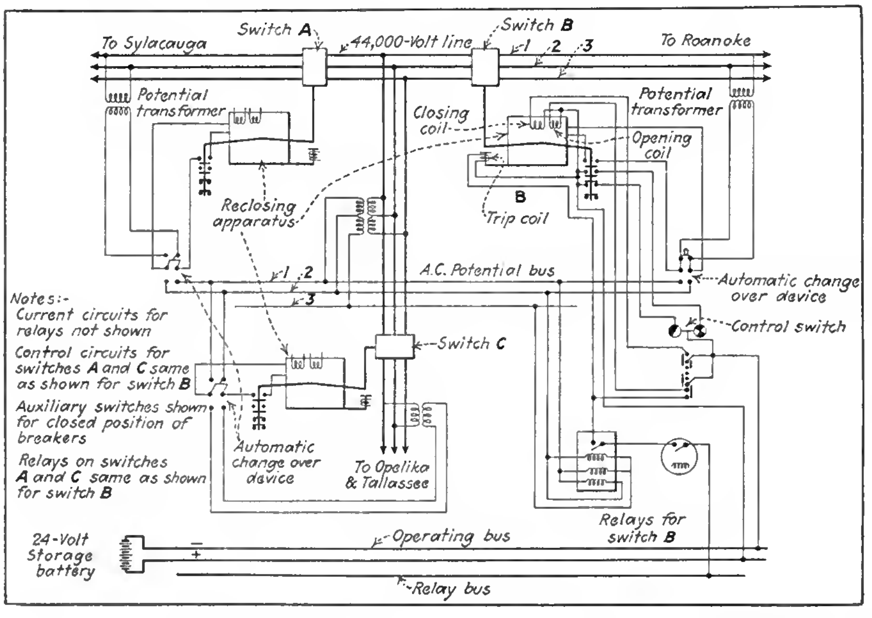


AUTOMATIC CHANGE-OVER DEVICE FOR POTENTIAL ON RECLOSING SWITCHES

motor circuit of the reclosing device. Should any breaker open automatically, the reclosing device will close it after a one-minute period without affecting the other breakers. Through this arrangement each feeder switch becomes automatically operated practically as though controlled by a separate reclosing device, thus reducing considerably the first cost.

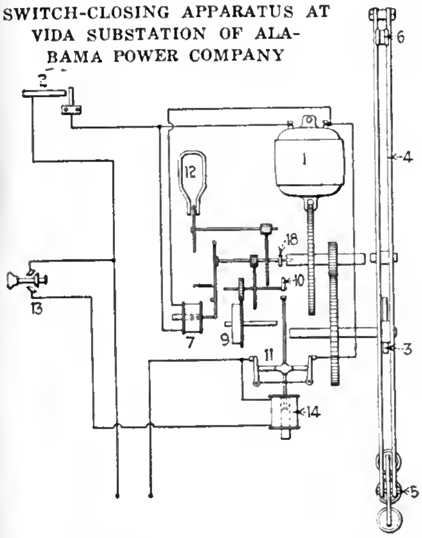
More recently the reclosing equipment provided with trip free attachment, trip coils and opening coils has been installed at Opelika substation, making this station almost fully automatic. The wiring of the control circuits is shown in one of the accompanying diagrams. The reclosing equipment on switches *A* and *B* takes its potentials from potential transformers on the respective lines. Switch *C* gets its potential from a contactor (shown in detail) which automatically makes connection to the transformer which is energized.

On the reclosing device furnished for the Opelika substation the trip-free attachment is a set of auxiliary levers working in between levers (4) on the schematic diagram of the reclosing equipment and arranged with latches and trip coil so that these



OPELIKA SUBSTATION MADE PRACTICALLY AUTOMATIC BY SWITCH RECLOSING DEVICE (AUTOMATIC CHANGE-OVER SWITCH SHOWN ABOVE)

SWITCH-CLOSING APPARATUS AT VIDA SUBSTATION OF ALABAMA POWER COMPANY

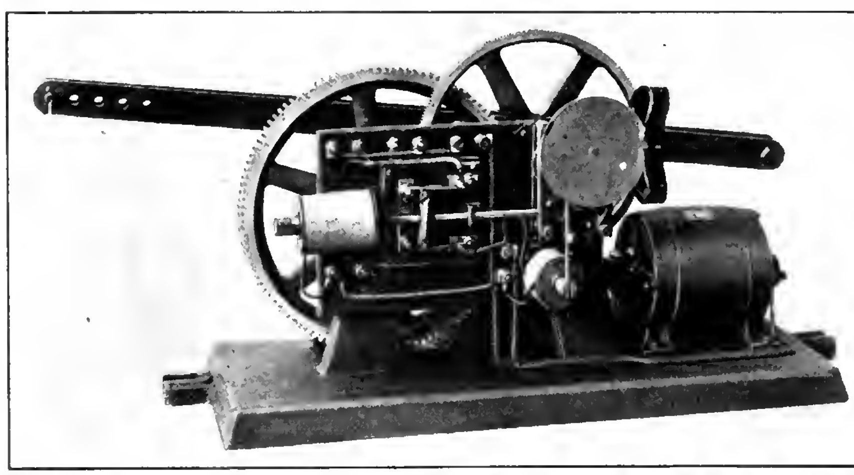


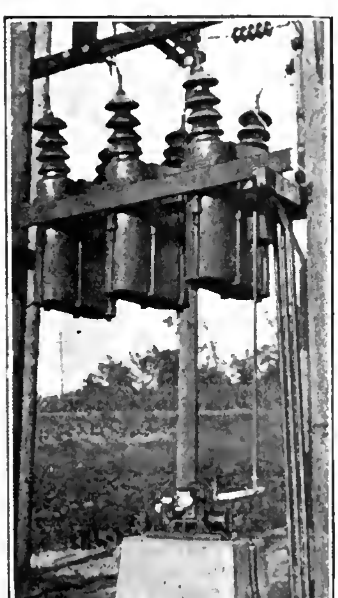
The small motor (1) for driving the gear train is designed for alternating current at 110 volts. The auxiliary switch (2) is so mounted on the oil breaker that when its blades are opened the contacts (2) are closed, thus establishing a current supply through cut-out switch (11) to the motor. The cam (3) attached to the main shaft of the large gear in revolving moves the lever (4) in such a way as to put the springs (5) under tension. When the rod (6) has reached the lowest point in its travel the mechanism of the switch to which the reclosing device is attached latches to close its contact when operating handle is moved in the opposite direction. As the cam (3) revolves further the tension of the springs is released for returning the lever (4) to its original position, thus closing the switch. When the circuit is closed through motor, potential across its terminals is applied directly to the clutch magnet (7) and the clutch (8) is made to engage with the revolving shaft. Movement of the gear train controlled through the clutch (8) winds up the spring on the larger gear (9). As the gear train continues to move the lever (10) revolves into contact with push rod controlling the cut-out switch (11) and finally the switch is opened, thus disconnecting the current supply to the motor (1) and stopping the operation of the device. The stop under lever (10) may be adjusted so that the motor is shut off when the cam revolves for closing switch once, twice, thrice or any predetermined number of times. As soon as the cut-out switch (11) opens the potential is removed from the clutch magnet and the clutch (8) disconnects the reset mechanism from the shaft. The spring (9) unwinds, reversing the movement of the gears, and returns the reset mechanism to its original position for another cycle of operation. The magnet and disk (12) retard rapidity of motion as gear train is reversing to original position after operation of device. Assuming stop is set under lever (10) for a cycle of two switch operations, then when closing contacts (2) are closed cam will close switch, say, after an interval of one minute. Trouble still being upon the circuit, the switch automatically reopens instantly, and then current supplied through contacts (2) is continued to motor until second closing operation, at which time the lever (10) operates cut-out switch and the device becomes inoperative until pull button (13) on switchboard is made to energize the reset solenoid (14) for reclosing the cut-out switch (11).

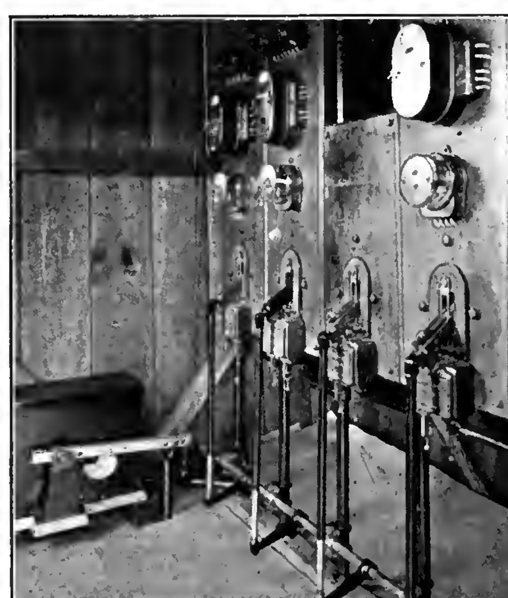
features become a part of the device instead of the oil switch itself. In other words, energizing the trip coils releases the auxiliary levers which are connected to the main breaker and permits the breaker to drop open. The reclosing device is immediately set into motion and the cam operates to lift the levers (4) to relatch the auxiliary levers at the upper end of the stroke and to bring both the auxiliary levers and levers (4) down together as the roller travels along the vertical face of the cam for closing the switch. The opening coil is attached to the present reset solenoid or closing coil and makes it possible to remotely control the opening of the cutout switch (11). This attachment eliminates the use of the Westinghouse KN-relay. Westinghouse control switch No. 271787 is easily applied for control of the device.

Reverse power relays on switches *A* and *B* and overload relays on switch *C* provide the necessary protection. The potentials for the reverse-power relays are taken from the potential transformers which actuate the reclosing devices. Phases 1 and 3 are wired through auxiliary contacts on switches *B* and *A* respectively, so that in case either incoming line is out of service for repair or maintenance work there will be no danger of a feed back from the "live" line.

In case of trouble on the Sylacauga line, switch *A* will open automatically and will reclose as soon as the line is energized from Sylacauga. If the potential coil for switch *C* is connected to the potential transformer on this line, it will automatically be switched over to the potential transformer on the Roanoke line by the device mentioned above, thus keeping the reclosing device on switch *C* operative. If the trouble occurs on the Roanoke line, the reverse operation takes place. In case of trouble on the Opelika feeder the device on switch *C* will operate to restore service. When trouble occurs on the two incoming lines and the Opelika feeder all three switches will open automatically. The switch on the incoming line which is first energized will close, and a fraction of a second later switch *C* will close and restore service to Opelika.







ALABAMA POWER COMPANY SUCCESSFULLY DEMONSTRATES THE USE OF RECLOSING SWITCHES

Top—Reclosing device that is shown elsewhere schematically. Left—44,000-volt, 300-amp. G. E. KO-26 oil switch operated for over a year with automatic device. Right—Four 2,300-volt feeder switches at Dora, operated by single reclosing device.

As soon as one incoming line switch has opened and remained so the reverse-power relay on the other incoming line is inoperative since the potential circuit has been opened as explained above. This will not matter, however, as switch *C* still has overload protection which will take care of trouble on the Opelika feeder, and in case of trouble on the incoming line service will be interrupted to Opelika anyway, so that automatic operation of either incoming line switch is not necessary when the other one is open.

It will be noted that the automatic devices are connected to the pull-button control switch, in such a manner that they can be operated from the board like regular electrically operated breakers.

This reclosing device, which is now being manufactured by the Southern States Equipment Company, has extensive application to all clases of automatic switching apparatus erected at isolated stations with or without regular attendance and where there are no large storage batteries installed or the available alternating-current capacity for operating such a device may be small. Should expense for the purchase of potential transformers to furnish alternating-current supply become prohibitive, the device may be altered to operate from the type of storage battery commonly used in automobiles. Typical installations include switches, controlling feeders at mines where overloads are frequent and attendance irregular, isolated substations on transmission lines supplying small distribution systems and feeder substations of a control-station system where automatic operation serves materially to reduce yearly costs. The simplicity of the apparatus makes for low manufacturing costs and minimum maintenance expenditures with very little attention except occasional oiling and inspection.

Superintendent of Distribution.
Alabama Power Company,
Birmingham, Ala.

# Extracts from an Operating Code

BY FIELD EDITOR ELECTRICAL WORLD
New York, N. Y.

## Instructions for Operating Feed-Water Heaters

ACCORDING to the operating code of the Philadelphia Electric Company, the three principal reasons for heating feed water are: (1) To utilize the heat of exhaust steam which would otherwise be wasted. One per cent of over-all efficiency is gained per 10 deg. F. increase in temperature of the feed water. (2) To prevent excessive stresses in the boiler caused by cold water striking heated surfaces. (3) Because dissolved air in the feed water is driven off by heating to 212 deg. F., and this decreases the amount of corrosion in the boiler and economizer.

In filling feed-water heaters, exhaust steam must be admitted slowly at first, to allow the water to heat uniformly, otherwise unequal expansion strains would be set up. The discharge valve is opened slowly to prevent the cool water of the incoming heater from reducing the temperature of the feed water from other heaters then in use. Vents on the heater must be kept open in order to allow air to escape which has been liberated by heating the water. The above code gives the following instructions for putting a heater on the line and for taking it off:

PUTTING A HEATER ON THE LINE

1. See that the drains are closed.
2. See that the vents on the heater are open and remain open.
3. See that the gage glasses are open and in operation.
4. See that the water valve on the seal is open and fill the seal, then cut down the water supply to a small amount.
5. Open the water-inlet valve and exhaust-steam valve slowly.
6. See that the float valves are operating freely.
7. When the heater has reached the operating level, partly open the discharge valve to the boiler-feed-pump suction line.
8. Open the exhaust-steam valve wide. When the operating temperature is reached, open the water-inlet and discharge valves wide.
9. See that the proper amount of pressure is obtained in the exhaust-steam header.
10. Open any trap discharge lines that lead to the heater.
11. See that the valve on the connection between the heater and float tank of the weir recording apparatus is open.
12. See that heaters divide the load equally and that the meter mechanism is operating properly.

TAKING A HEATER OFF THE LINE

1. Partly close the water-feed valve and allow the water to reach minimum level.
2. Close the exhaust valve.
3. Shut off all traps entering the heaters.
4. Close the feed-water valve.
5. Close the discharge valve to the pump suction line.
6. See that the vents are open.
7. Open the drain.
8. Before opening the heaters, close the vents.

## Using Induction Motor to Start Frequency Changer

IN ORDER to raise the rotor of frequency changers from the bearings by a film of oil, thereby requiring a much smaller starting motor than would be needed were the rotor not lifted, oil is supplied to the bearings under pressure. The following instructions for starting frequency changers with an induction motor and for shutting them down have been abstracted from the operating code of the Philadelphia Electric Company:

STARTING

1. When an oil pump is supplied, start it.
2. When the oil pressure reaches the proper value, open the valves admitting oil to bearings.
3. Adjust the valves on the pipes feeding the bearings so that the one farthest from the pump will be opened widest. If this does not lift the shaft from the bearing, open one valve at a time wide until the shaft does lift. Then adjust the valves as stated above.
4. See that the controller is in the starting, or "off," position.
5. Close the switch of the starting motor, observing the ammeter.
6. When the starting motor current falls to a specified value, cut in the next step of the controller, again allowing the current to fall in the specified value. Repeat until the proper controller point for synchronizing is reached. This point should be marked on the controller.
7. Shut down the oil pump.
8. Put on the fields of 60-cycle and 25-cycle machines and raise the voltage of the machine to be synchronized first to that of its bus.
9. When one or more sets are already in operation, plug in the synchronoscopes of both machines and bring the incoming set to approximately synchronous speed by varying the field of the machine to be synchronized last. When pointers of the synchronoscopes are in proper position with respect to each other (determined by a synchronizing calculator) close the oil switch of the machine to be synchronized first, when it is in synchronism.
10. Open the switch of the starting motor, place the controller in the "off" position, adjust the voltage of the machine to be synchronized last, and close its oil switch.

SHUTTING DOWN

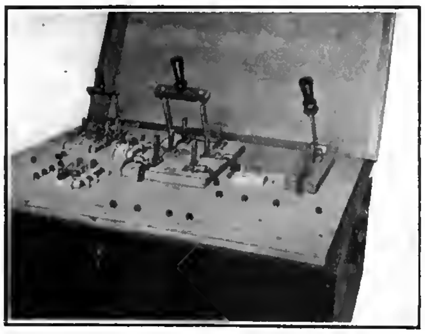
1. Adjust the power factor of the machine to be taken off first (either 25-cycle or 60-cycle) to unity.
2. Open oil switch of that machine.
3. Adjust the power factor of the other machine to unity and open its oil switch.
4. Cut in all resistance of both field rheostats.
5. Open the field switches.

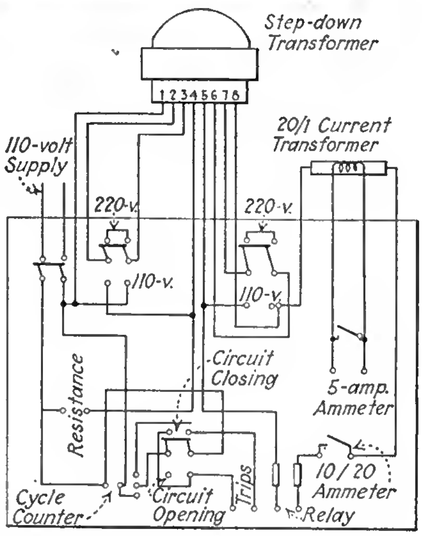
## Portable Set for Testing Relays

IN TESTING induction-type relays during the past it has been the practice of the Alabama Power Company to base all settings on a test curve showing relay characteristics when the 4-amp. tap is being used. This was done because it was impossible to pass more than 22 amp. through the relays with the portable test sets then available. It was found, however, that a test curve based on the higher-current taps would not pass through the same points as one based on the 4-amp. tap. A difference of 2 cycles to 10 cycles was observed between 150 and 400 per cent current setting.

Consequently the relay-testing set shown in the accompanying illustration was developed and is now being used in each station. All of the test equipment except the cycle counter, ammeter and adjustable resistor are contained in the test set. The test man carries these and also leads, contact parts, air valves for relays, oil and a folder containing curves and data on all relays on the system. The resistor is a Ward Leonard loading rheostat similar to the "RLR-120" except that it has a capacity of 10 amp. in steps of 0.1 amp.

A step-down transformer is used with the set to make it possible to obtain large current at low voltage without overloading the 110-volt supply. The windings of the primary and secondary may respectively be connected in series or parallel by means of the double-throw switches on the test set. This provision, together with the lower right-hand knife switch which cuts out a high reading ammeter when current values are such as to require the use of the current transformer shown above, enables the operator to obtain practically any current required for testing relays.





FIGS. 1 AND 2—EXTERIOR AND WIRING CONNECTIONS OF RELAY TEST SET

The coil and contact of the relay to be tested are connected across the four terminals at the bottom of the winding diagram. If the relay is of the circuit-closing type, the double-throw switch to the left is placed in the upper position. If the relay is of the circuit-opening type, the double-throw switch is placed in the lower position.

The resistance mentioned above is a variable resistance used to regulate the current in the step down transformer primary.

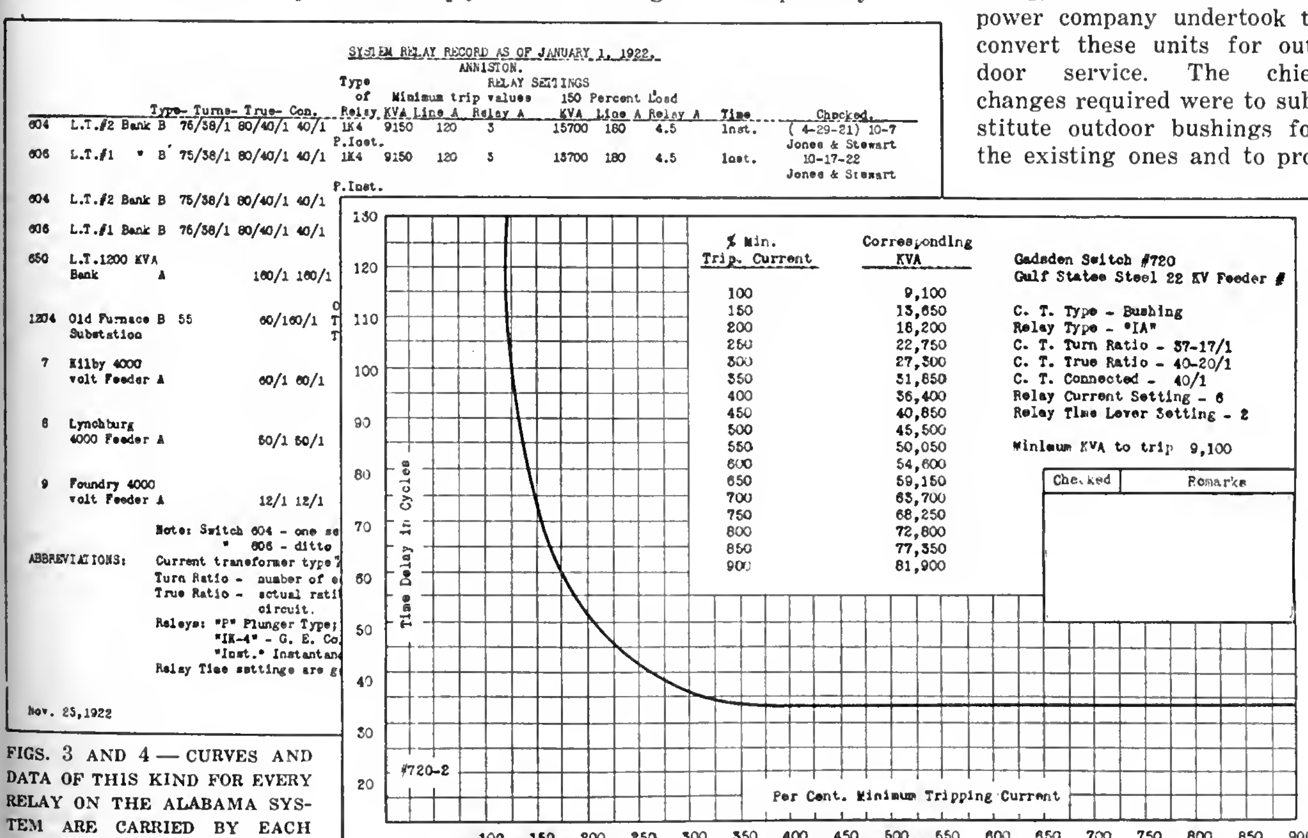
## Indoor Breakers Converted to Outdoor in Need

BEING faced in an emergency with the immediate need for outdoor circuit breakers and having nothing but indoor units which had the desired rating, the one Southeastern power company undertook to convert these units for outdoor service. The chief changes required were to substitute outdoor bushings for the existing ones and to pro-



FIGS. 3 AND 4 — CURVES AND DATA OF THIS KIND FOR EVERY RELAY ON THE ALABAMA SYSTEM ARE CARRIED BY EACH TEST MAN

vide a weatherproof housing for the operating mechanism.

Consequently the old terminals were removed and outdoor bushings substituted without any change except to provide cork gaskets. Then a housing for the operating mechanism was improvised. This was done by bending angle irons, which were to serve as the attachment of the housing to the circuit-breaker cover, to conform to the contour of the breaker cover. Cork gaskets were then placed under the angle irons and drilled to receive cap screws in the breaker cover. At the corners the angle irons were welded together. The lower part of the housing (in two parts), which was made of ⅛-in. sheet metal, was riveted to the angle irons, while the top, made of thinner metal, was fastened to the lower part with wing nuts.

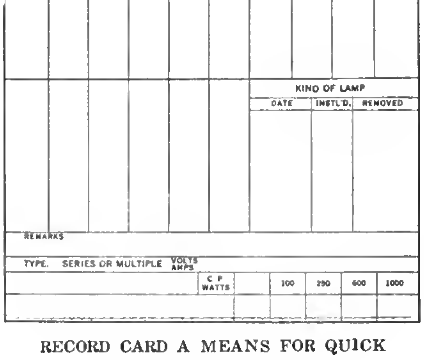
## Keeping Street-Lighting Records

A CARD-INDEX file system has been found very satisfactory by the Detroit Edison Company for keeping records on street lamps. The 5-in. x 5-in. card shown in the accompanying illustration is used. It contains information showing the individual number of each lamp, the location of the lamp and the type of fixture in which the lamp is used, and it affords means for recording burn-outs and broken globes, so that the life of each lamp can be checked



RECORD CARD A MEANS FOR QUICK RECAPITULATION OF LAMPS AND FIXTURES

against the guarantee. In addition, the system affords a means for quick recapitulation of lamps and fixtures in service and permits billing against small towns to be made readily and accurately.

## Boiler Paint Stops Corrosion of Turbine Disks

INTERNAL boiler paint has been successfully used for many years to prevent corrosion and adhesion of scale on internal surfaces of boiler drums. About a year ago engineers of the Southern California Edison Company conceived the idea of experimenting with internal boiler paint to prevent the trouble they were experiencing from corrosion of the wheel disks of their steam turbines. Some of the wheel disks of a 20,000-kw. vertical Curtis turbine were thoroughly cleaned and painted, while other disks in the same turbine were not painted.

About a year later this turbine was opened for inspection and the effect of painting the wheel disks noted. Practically no further corrosion was noticeable on the disks which had been painted, while those which had not been painted had corroded at about the former rate. Before adopting the use of boiler paint to prevent disk corrosion the depreciation of turbine-wheel disks due to corrosion was about $250 per disk per year.

## Cost of Building 3,000-Kva. Transformer Substation

THE accompanying itemized costs of a 3,000-kva. substation, exclusive of land, have recently become available in connection with a Massachusetts substation extension begun in 1917 and completed in 1919. Three 1,000-kva., 22,000/2,300-volt units were installed with complete substation equipment as listed.

SUBSTATION INSTALLED AT A COST OF $8.56 PER KVA.

| | |
|---|---|
| Three 1,000-kva. transformers | $9,103 |
| 100 lb. blotting paper for oil filtration | 22 |
| Two L-3V floodlighting units | 88 |
| One 22,000-volt lightning arrester | 745 |
| One No. 102,879 relay | 15 |
| Six L-224,644 overload relays | 127 |
| Two PP-St. circuit-breakers complete | 2,529 |
| Fifteen three-unit stud anchorages | 7 |
| Three 300-amp. air-break disconnecting switches | 484 |
| Two S-224,644 overload relays | 44 |
| Two oil switches complete | 867 |
| One tank-lifting device | 35 |
| One panel and fittings (1779, SOCR) | 32 |
| One storage battery complete | 946 |
| One motor generator, 2.25 kw. | 221 |
| One battery panel with instruments | 264 |
| 1,282 lb. electrolyte | 33 |
| 250 ft. 1¼-in. galvaduct | 52 |
| 75 ft. 1-in. Sheraduct | 13 |
| 80 ft. ½-in. Sheraduct | 7 |
| Two steel cabinets | 10 |
| Condulets and covers | 89 |
| Miscellaneous | 1,145 |
| Two 2,200-volt potential transformers | 40 |
| Two 1,000-amp. current transformers | 74 |
| One 5/1,000-amp. type H-2 ammeter | 27 |
| One 1,000/5-amp. 220/100-volt wattmeter | 22 |
| One 5-amp., 110-volt, 4,000-kw. wattmeter | 56 |
| One 175-volt voltmeter | 34 |
| 800-ft. fiber conduit | 52 |
| 275 3½-in. couplings | 26 |
| 26 3½-in. 90 deg. conduit bends | 52 |
| 54 2½-in. Sheraduct bends | 26 |
| 280 ft. 1,000,000-circ.mil lead cable, 5,000 volts w.p. | 588 |
| 200 ft. 1,000,000-circ.mil single conductor cable | 330 |
| 357 lb. ½-in. copper tubing | 171 |
| 194 lb. 1-in. copper tubing | 95 |
| 200 ft. ½ in. x 2-in. bar | 137 |
| Three type MS 220-volt, three-conductor potheads | 87 |
| Seven type TS 2,300-volt one-conductor potheads | 90 |
| 275 ft. No. 6 twin lead-covered wire | 66 |
| 280 ft. 124-conductor lead-covered cable | 80 |
| 282 ft. 123-conductor lead-covered cable | 72 |
| 100 ft. four-conductor stranded copper cable | 10 |

# Central Station Business

Advertising, Selling and Service Methods
Commercial Organization and Management, Customer and Trade Relations, Public and Financial Policies, and Reports of Company Plans and Experiences

## A Merchandise Sales Code

**Fundamental Principles Which Should Be Observed by the Central Station Commercial Department in Selling Appliances**

By W. E. Clement

Commercial Manager New Orleans Public Service Inc.
General Chairman Sectional Joint Committee for Business Development of the Southwestern Geographic Division, N. E. L. A.

In going after new business the commercial manager of a central-station company should do so with a broad understanding of what will be profitable to the company as a whole—not merely what will make a good showing from a spectacular viewpoint. This is particularly true in the sale of appliances where the objective is twofold—first, to build up the connected load, and, second, to conduct this branch of the business so that it will at least be self-sustaining and preferably show an actual net profit. Though there is always a certain amount of this business which comes in of its own volition, it is only by carefully working out and following a definite plan that it can be made to produce a maximum volume of business and earn a profit.

W. E. CLEMENT

It sometimes happens that the sale of merchandise fails to pay its way not because of a lack of volume but because some of the cardinal principles of any successful retail business have been overlooked. Central-station merchandising does not differ greatly from other businesses, but there are certain broad principles which should be carefully adhered to if the department is to be successful and stand upon its own feet. Merchandise sales operations may be classed under six general headings — buying, stock keeping, sales floor and window displays, sales policy, sales advertising and the sales force. The organization and handling of these fundamental features may advantageously be carried out as follows:

*Buying.*—Buy the best appliances made. Stick to one manufacturer's complete line when all items are as good or better than similar items of any other line. Purchase so as to secure quantity discount, but bear in mind that slight differences in discounts are not usually a saving unless the additional merchandise can be moved quickly.

Always have at hand up-to-date stock sheets from your manufacturers and jobbers on all fast-moving merchandise, and know the time required to place this merchandise in your storeroom.

Grant all salesmen an interview. Let them wait for you, but make them comfortable while waiting. Don't let them waste their time or yours, but let them know that you also sell things, and that you like to make it easy for them to sell to you when possible. Not many new good things are missed if you are easy to approach.

*Stock Keeping.*—There should be no uncertainty or leaving to chance as regards the proper and accurate receiving, checking, pricing and storing of merchandise. A few months of uncertainty or carelessness may take high-priced help hours to straighten out. If $100 in currency is being received, it is accurately accounted for. If merchandise is being received for which $100 is to be paid, should it be any less accurately accounted and less properly cared for?

*Sales Floor and Window Displays.*—Equip your sales floor and windows with modern but not necessarily expensive store and window fixtures, including the best and most correct lighting installation in town. Arrange your merchandise so that a customer can locate without effort the kind of appliance she may be in search of and, at the same time, be aware of seeing distinctly several other kinds of appliances that she may not possess.

On the sales floor make groups of the different types and sizes of the same kind of appliances. As a rule, display one article only of each of the items of your complete line. Sell the articles on display. A shop-worn article should be offered at a big reduction in price to force a quick sale. These methods help to keep your merchandise appearing fresh and new.

The show windows are so valuable a sales medium that a special study of window trimming is necessary in order to get the return from them that you are justly entitled to expect. It is not necessary to mention that sales floors and windows can never be kept too clean and neat.

*Sales Policy.* — Form your sales policy from a definite knowledge of such important factors as the possibilities and limitations of the field you expect to cover and the amount of money that can be invested in stock and time-payment accounts. Consider the relation of short and long-time payments to gross sales; consider the manufacturer's guarantee on the merchandise to be handled; consider what arrangements are to be made with other departments of the utility, so that a merchandise sale may be handled as any other efficient retail store would handle a similar sale; consider whether it is intended to promote intensely, and perhaps at a loss, any or

all new but practical appliances; consider what percentage, if any, of net profits on merchandise sales as a whole is to be sacrificed for rapid increases in kilowatt-hour sales; consider the number and kind of campaigns to be run yearly; consider the relations you expect to maintain with the contractor-dealers, and consider the experience and ability of each individual in the sales force. After weighing such factors as these you are in a position to form a sales policy which will be in keeping with the sales service you expect to render.

*Sales Advertising.*—Consider carefully all possible advertising mediums and their relative value to you. Make use of, but not abuse of, all free advertising matter supplied by manufacturers—such as stickers for bills, descriptive pamphlets, counter stands, window cards, price tags, etc. Estimate the amount to be spent with each of such paid advertising mediums as you expect to use. Time all advertising so that you are featuring the merchandise your sales force is focusing on. Unusual methods and special attention are necessary when conducting a campaign. Adopt the slogan, "Tell it to them quickly, and tell it to them often." Housewives are the biggest and best buyers of electrical merchandise. They have been educated to certain styles of advertising—direct your advertising to them along the same general lines that the big successful retailers use. Study advertising. The biggest and most successful merchandisers personally direct their advertising.

*Sales Force.*—The sales manager must have first a thorough knowledge of the inside workings of a utility and the service it is expected to render. Next, he must understand merchandising as well as, and preferably better than, the average successful retailer. A low-priced man, if he really is a low-priced man, will not do, as the entire standard of the utility will be lowered and the investment will prove expensive.

A sales manager of ability should receive broad authority and be subjected only to the advice and regulation of the general manager or, in large holding companies, to the instructions of a sales manager in charge of all sales operations for the holding company. Selection of this man is vital to the promotion and best interests of the utility, including the profitable handling of merchandise.

Merchandise salesmen should be carefully selected, especially considering their natural or acquired ability to meet and please the public and to work without friction with their business associates.

### Morning Meetings Essential

The sales manager, when possible, and his assistant at all other times, should conduct a morning meeting, starting at a fixed time and ending ordinarily at a fixed time. This brings the sales manager in personal contact with his force and gives him an opportunity to issue instructions and discuss sales problems.

Merchandise salesmen may be assigned to sections of the territory served and maintain a perpetual canvass and "follow-up" of each user of electric service in this section, using any good method for keeping up-to-date records of this work. When organizing a campaign these records are of great value.

The territory salesmen will probably get the best results if paid a nominal salary plus a liberal commission, provided that a careful survey has been made of the possibilities for sales and that the man of average ability is then allowed to make the average income for similar work. This method weeds out the inefficient man and properly compensates the man of exceptional ability. A daily report of the sales of each individual salesman and a comparison of these reports establish a healthy condition of friendly competition in the department.

There should be constant help and training given the salesmen. Each individual should understand thoroughly the company's service and the merchandise he sells. Manufacturers' and jobbers' representatives can frequently be used as an aid to the instruction and training of salesmen.

As the sales force comes in daily contact with a great many of the company's customers who judge the utility by the promptness, courtesy and ability of these men, too much attention cannot be given to developing a truly representative organization of salesmen.

## Boston Electrical Home Opened

Under the auspices of the Boston Electric League, an electrical home was opened to the public on April 14 in the Wauwinet section of West Newton. Devices to be shown were selected by drawing lots, and the trademarks and makers' names were concealed in order to avoid any bias on the part of the visitor toward any particular type of equipment shown.

All branches of the local electrical industry co-operated in the work, together with a local real estate concern and a leading house furnisher who provided the setting for the electrical devices exhibited. About fifty appliances were shown, with adequate convenience outlets, in the seven rooms which compose the dwelling.

## Public Utilities as Community Builders

By Henry Bostwick

Manager San Francisco Division Pacific Gas & Electric Company

It has often been said that the prosperity of a community can well be judged by its public utilities, but I believe we should go a step further and say that all public utilities, particularly electric and gas companies, can and should be classed as community builders. However, the extent to which a utility assists in the upbuilding of a community and to what degree it merits being called a "community builder" depend in a large measure upon its public relations.

The Pacific Gas & Electric Company has given much thought and study to this matter of building and cementing better public relations. As an instance of what has been done along this line, it has been the practice of the company for some time to take parties of citizens on inspection tours through its various generating plants.

We feel that this has done more toward building better public relations than any other means that we could possibly have adopted. In the San Francisco division during the past year we have had the pleasure of a visit to our plants from the grade school teachers' association. There were 125 in this party, which visited the plants in the evening, and to use their own words: "It was an inspirational trip to all of us." Recently a women's organization known as the "See and Know San Francisco First Club" was conducted through the plants with the same result. In addition to personal visits to our plants representatives of the company are always glad to appear before any of the schools, mothers' clubs or other associations to tell about our industry. This practice

has always resulted in very favorable comment and appreciation from the members of these associations.

No branch of our service is receiving more constructive thought and application today than that of public relations. Not that we have been altogether neglectful of this important matter in the past, but conditions have arisen during the last three or four years which have brought it more forcibly to the attention of the managing heads of all institutions throughout the country, whether of a public or private nature. From our experience we believe that the central-station manager who is not taking advantage of such simple things as these inspection tours to foster and cement a better feeling toward and closer relations with his company in the community it serves is overlooking a valuable opportunity to build good will.

## Central Station Sells 1,120 Washers in Thirty-Day Campaign

THE Utah Power & Light Company, with general offices at Salt Lake City, continued its record-breaking pace in the sale of washing machines during March of this year, when a total of 1,120 machines were sold in a thirty-day campaign which has been an annual feature of the company's commercial program for several years past.

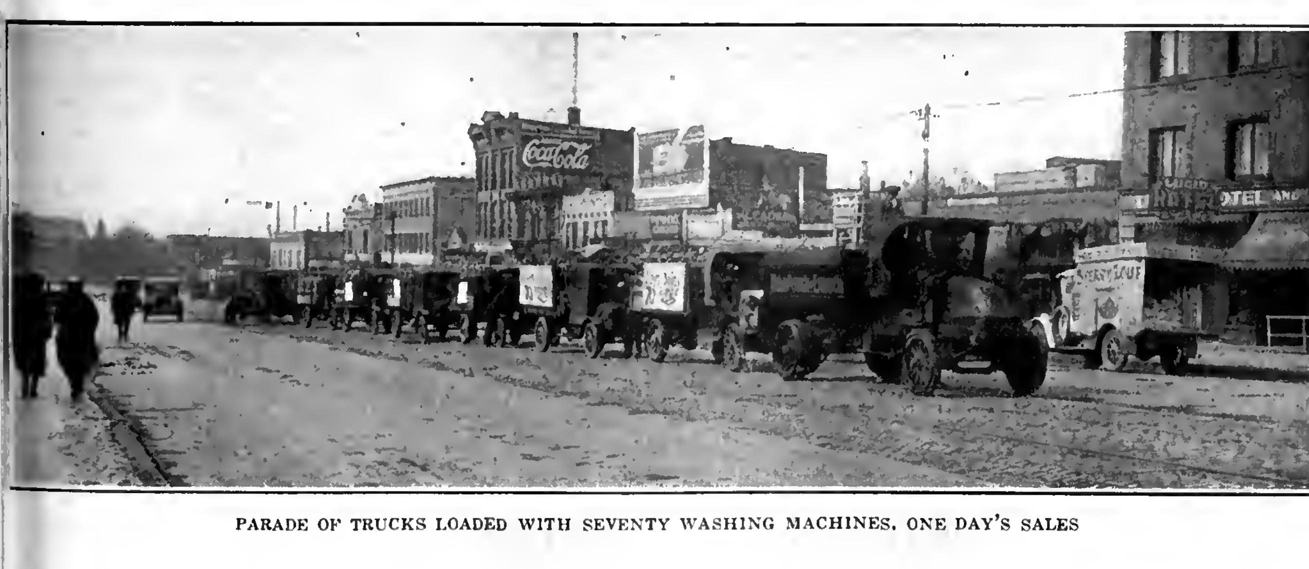
To dispose of this number of machines in that time in a widely scattered territory with a population of approximately 350,000 people distributed over a large part of Utah, southern Idaho and western Colorado is a splendid example of real central-station selling. The company serves in its entire territory 62,000 residence customers. At the start of the campaign a quota of 1,000 machines was set as the goal. This quota was divided proportionately among the eight divisions of the company's territory, and competition among these divisions was aroused by offering cash prizes for those which exceeded their quota, for the division which made its quota first and for the division which exceeded its quota by the greatest percentage. As in previous campaigns, this arrangement was a strong factor in the success of the drive.

TYPE OF ADVERTISEMENT USED IN WASHING MACHINE DRIVE

Easy terms of $1 down and $5 a month were offered and proved very attractive to customers. A liberal amount of newspaper advertising was used in all of the papers published throughout the company's territory. All the advertisements carried a slogan "A Copper Washer for a Silver Dollar," and the convenience, labor and money-saving features were also played up. A particularly interesting publicity stunt used to advertise the sale was a parade of several truckloads of washing machines on the main street of Salt Lake City, carrying a total of seventy washers representing one day's sales. Other features used to put the campaign over were banners on street cars, company automobiles and trucks; the delivering of washing machines from the front doors of some of the company's stores; distribution of 1,000 caps bearing the slogan "A Copper Washer for a Silver Dollar" to newsboys and others; placarding of freight cars loaded with machines; lettering of the sidewalk in front of stores, and the demonstration of machines in homes.

Daily sales reports were received by the general sales department at Salt Lake from the company's various divisions, and daily bulletins were forwarded to division managers and salespeople showing the relative standing of each division. This kept the enthusiasm and rivalry at a high pitch throughout the campaign. Daily sales letters were also sent out, encouraging those actively engaged to use their utmost energy in order that the quota might be reached or exceeded.

About thirty-five people were actively engaged in the selling of the machines, including some office employees who devoted part of their time to the work. These salespeople all worked on the outside, with the exception of about twelve inside salesmen. As in the past, the generous use of advertising, the selling of a thoroughly dependable piece of merchandise and the offering of terms within reach of every one were important factors in making the campaign a success and establishing what is believed to be another record.



PARADE OF TRUCKS LOADED WITH SEVENTY WASHING MACHINES, ONE DAY'S SALES

## Showing an Interest After Obtaining Business

MANY electric service companies will, when the question is raised, contend that they make every effort to show an interest in their customers after their application blank is signed, but the customers are not always so quick to agree with this contention. Actions speaks louder than words, and to make its service as near 100 per cent as possible the Georgia Railway & Power Company maintains a "greater service department." Four men are engaged in this department, which is really a field organization. They travel from customer to customer steadily, asking whether the service is satisfactory, if not why not, whether all equipment or apparatus is in service, and so forth. A record containing definite questions of this character is filled in for each customer and turned into the sales department promptly for immediate attention.

Minor repairs like mending of flatiron cord are made by the "greater service" representative, but major repairs necessarily are reported to the central office with other statements regarding service. The troubles are then adjusted by the electric service company or, if it is not the duty of the company to attend to them, the customer is informed how to get the work done.

In addition to the relatively detailed investigations of the greater service department representatives, the company has recently instituted a system of inquiry and investigation which is carried on coincidentally with the meter reading. As the reader enters the home he greets the lady-of-the-house with a "Good morning (or afternoon) Mrs. Blank" and makes inquiry as to whether the service is satisfactory and if not, in what respect it is deficient. When the reader reports back to the office in the afternoon he turns in reports of any complaints or requests for appliance adjustments. This innovation has served materially to improve customer relations and the time required for gathering the information has not appreciably increased the cost or time required for meter reading.

A great many prospects for gas and electric appliances are obtained in this way.

In the event apparatus, piping or wiring is found in a condition dangerous to life or property, or installed in such a manner as to be the cause of high consumption, a personal letter signed by the general sales manager is sent to the customer immediately after the visit, stating that the field man has reported that such and such a condition prevails and that same should be remedied.

The psychological effect of such methods alone, if no other advantage accrued, is worth the expense and time, says C. A. Collier, general sales manager. Furthermore, they prevent complaints accumulating and growing into general dissatisfaction that could only be eradicated with difficulty.

Form 2-616—20M—4-5-22

CUSTOMER REPORT

Date ..............................

Name .............................. Address ..............................

Service furnished: ELECTRIC LIGHTS, POWER, COOKING; GAS: COOKING, WATER HEATING.

A RECORD OF THE APPLIANCES IN SERVICE AND CUSTOMER'S ATTITUDE TOWARD THE COMPANY IS KEPT ON THIS FORM

## What Other Companies Are Doing

**Hartford, Conn.**—Following the offer of a limited number of shares of its stock to customers and their families on a cash or an installment basis, 1,075 shares were sold in the first four days by the Hartford Electric Light Company. The shares were sold to net 6 per cent to the purchaser. In a statement announcing this customer-ownership plan, Vice - President Samuel Ferguson pointed out that such a distribution represents a true and efficient "public ownership of utilities," in contrast to the form commonly advocated in socialistic circles, which should be more properly entitled "political ownership."

**El Paso, Tex.**—The employees of the El Paso Electric Ralway Company have formed a beneficial association to provide medical aid for employees who may be injured or become sick while in the services of the company. The monthly dues are $1 per month and the benefits include in addition to doctor and hospital service a death benefit of $1,000. All employees of the company, both men and women, whether in the railway or light and power departments, are eligible to membership upon meeting the entrance requirements.

**Montpelier, Vt.** — In a recent six months' house-wiring campaign by the Montpelier & Barre Light & Power Company 3,536 outlets were added, an average of sixteen outlets per house. Eighteen towns were canvassed and 210 meters added to the system. Of 6,664 homes in the territory, 5,416, or 84 per cent, are now wired and being served by the company.

**San Francisco, Cal.**—The annual report of the Pacific Gas & Electric Company was broadcasted on April 10 from the Mercantile Trust Company's radio station. Wiggington E. Creed, president of the power company, delivered the message. This is the first annual report to the stockholders of a public utility that has been sent over the radiophone on the Pacific Coast.

**Lowry City, Mo.**—The West Missouri Power Company has purchased the Osceola Light & Water Company of Osceola, Mo. A transmission line will be constructed from Lowry City to Osceola to supply the electric service in Osceola, and the water plant will be equipped with motors so that it can be operated electrically.

# Digest of Electrical Literature

Including Brief Abstracts of and References to
Important Articles Appearing in the Scientific and Engineering Press
from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Hydro-Electric Development in California.*—G. C. TENNEY.—In its Big Creek-San Joaquin River hydro-electric project, where approximately $300,000,000 is being spent to produce and market 1,400,000 hp. of electrical energy, the Southern California Edison Company is keeping abreast of the ever-increasing power demands of the rapidly growing territory to which its service extends. This ten-page, amply illustrated article deals with the general engineering features of this project. Tables give the capacity of present power houses, connected load in horsepower, miles of transmission lines, number of meters employed, uses to which electrical energy is being applied, summary of tunnel lines in the Big Creek-San Joaquin development, and growth in number of stockholders.—*Journal of Electricity and Western Industry*, April 1, 1923.

*Purification of Boiler Water.*—F. H. RHODES.—The selection of the proper method of water purification is one of the important problems in any steam-power plant installation. In this selection there are several factors to take into consideration. These include not only the nature and the amounts of the impurities in the raw feed water and the costs of construction, operation and maintenance of the water-purification plant, but also the amount of water to be treated daily, the daily and seasonal variations in the amounts of impurities, etc. The author treats mathematically several methods for purifying water and illustrates each with an actual example.—*Sibley Journal of Engineering*, April, 1923.

## Generation, Control, Switching and Protection

*Synchronizing Torque of Ljungstrom Turbo-Generator Set.*—T. KOMARU.—The author considers the power oscillation between synchronous machines of different frequency with special reference to the Ljungstrom turbo-generator set, discussing the circulating current between machines, exciters and generator characteristics.—*Journal of the Institute of Electrical Engineers of Japan*, March, 1923.

*Transient Phenomena Arising in Transformers from Switching Operations.*—S. A. STIGANT.—The occurrence, effects and prevention of the transient disturbances arising as a result of switching are considered under the divisions of (a) switching-in current rushes, (b) switching-in pressure rises and (c) switching-out pressure rises. The initial value of the current taken on low load by the transformer at the instant of switching in is determined by the point of the pressure wave at which switching in occurs and is also dependent on the magnitude and polarity of the residual magnetism which may be left in the transformer core after previous switching out. The exact conditions encountered when switching in and out at various points on the wave and with various amounts of magnetism remaining in the transformer coil are considered.—*Electrical Times*, April 5, 1923.

*Developments in Auto-Valve Lightning Arresters in* 1922.—A. L. ATHERTON.—A four-page abstract of this paper, presented at the midwinter convention of the A. I. E. E., may be found in the ELECTRICAL WORLD for Feb. 17, 1923, on page 385.—*Journal of the A. I. E. E.*, May, 1923.

## Transmission, Substations and Distribution

*Characteristics, Operation and Maintenance of Underground Cables.*—A. I. TRACEY.—A page-and-a-half abstract of a paper presented before the Electrical Power Engineers Association (England). The author considers the general characteristics of a three-core transmission cable and how these characteristics function and discusses the operation and maintenance of such cables. The capacity of these three-core cables, their measurement and the determination of capacity current, self-induction characteristics, potential gradient, presence of moisture in the dielectric, relation of insulation thickness to working voltage, the concentration of stresses set up by local high-frequency current in cables, safe current with which a given cable can continuously stand and cable-jointing methods are other features covered.—*Electrical Times*, April 5, 1923.

*The Neutral Grounding Reactor.*—W. W. LEWIS.—An abstract of this paper may be found in the ELECTRICAL WORLD report of the A. I. E. E. spring convention, May 5, 1923, on page 1020.—*Journal of the A. I. E. E.*, May, 1923.

*Use of Single-Core Sheathed Cables for Alternating Currents.*—W. CRAMP.—It is frequently a matter of convenience to use single-core, lead-covered cables for transmitting power by means of alternating current, and in such cases the magnitude of the loss arising from the eddy currents induced in the lead sheath becomes a matter of importance. The eddy losses in the sheaths of these cables may be divided into two groups, called "sheath eddies" and "sheath-circuit eddies." The latter occur only when one or more cables have their sheaths connected at more than one place. The losses are analyzed for a single cable, a pair of single-phase cables and a set of three-phase cables. It is shown that the sheath eddies are in all cases negligible and that the sheath-circuit eddies may be kept within reasonable limits by proper regulations regarding the spacing of each cable in respect to the others.—*Journal of the Institution of (British) Engineers*, April, 1923.

## Units, Measurements and Instruments

*Measurements of Transients.*—F. E. TERMAN.—An abstract of this paper may be found in the ELECTRICAL WORLD report of the A. I. E. E. midwinter convention, Feb. 24, 1923, on page 450.—*Journal of the A. I. E. E.*, May, 1923.

*Comparison of Performance of Oil Circuit Breakers.*—P. BENDMANN.—A number of oil switches, made by different concerns, are critically investigated as to their performance characteristics, such as ruggedness of contacts, depth of arc under the oil level, air space above the oil, churning of the oil and speed of opening. Two modern types of high-capacity switches are shown which embody most of the required characteristics for a dependable operation. Of special interest in these breakers are provisions to have the generated gas break up in small gas bubbles, contact knives arranged edgewise, a ventilated gas-accumulating chamber, arcing tips in a pressure-proof pot and compression air pockets to act as gas-pressure buffers. — *Elektrotechnische Zeitschrift*, March 15, 1923.

*Preparation of Platinum and of Platinum-Rhodium Alloy for Thermocouples.*—R. P. NEVILLE.—The Bureau of Standards has prepared in its laboratories thermo-element platinum and platinum-rhodium alloy for standard thermocouples, to determine what performance might justly be required of such instruments. The melting of the pure metal and of the alloy was carried out in an Ajax-Northrup high-frequency induction furnace in crucibles of lime and thoria. Platinum and platinum-rhodium alloy, superior in quality to the best material of this kind formerly in the possession of the bureau, was prepared. — *Paper presented before American Electrochemical Society, New York*, May 3-5, 1923

## Illumination

*Development of Electric Illumination of Railroad Cars.*—H. LÖWL.—After a short description of the different systems used on European railroads to illuminate their coaches, the author describes an automatic system which uses an axle-driven direct-current generator of 300 watts to 3,000 watts output connected over an electromagnetically operated mechanism to a battery of twelve cells. To insure uniform polarity at forward or backward run the brush yoke of the dynamo is automati-

cally shifted. Under most unfavorable conditions the voltage applied to the lamps in the car may vary between 24 and 27.6, or a variation of 15 per cent. —*Elektrotechnik und Maschinenbau*, April 1, 1923.

*Stage-Lighting Equipment and Its Application.*—A. L. POWELL.—A comprehensive discussion of the possibilities and limitations of the various standard devices for producing the multitude of light and color effects demanded on the stage, with particular reference to foot and border lights, bunch and spot lamps, "effect" apparatus and colored lamps, together with some brief notes on switchboards and wiring, is given. The article is well illustrated, showing various types of lamps and lighting equipment employed.—*Electrical Record*, April, 1923.

## Motors and Control

*Induction-Motor Developments.*—K. SACHS.—The author describes in this paper some of the latest designs of induction motors, selected from recent patent literature, with special centrifugally operated devices to start the motor with a wound armature and to short-circuit the winding at full speed. Such motors combine the easy start of the phase rotor with the desirable running characteristics of the squirrel-cage rotor. Some designers go even so far as to provide three steps of gradual short-circuiting, with a resistance mounted on and running with the shaft. Other models start with the rotor winding in "Y," then change it into delta, and finally short-circuit it. A motor with a centrifugal starting device, reliable and not too complicated, could be easily built as a totally inclosed type and would be a very useful machine in mines with explosive gases, doing away with starters having open or otherwise poorly inclosed contacts. *Bulletin de l'Association Suisse des Electriciens*, March, 1923.

*Graphically Designed Starting Apparatus.* — S. OGAWA. — The author describes a simple graphical method of designing a direct-current shunt and series-motor starter and starting compensator, taking into consideration the proper time elements.—*Journal of the Institute of Electrical Engineers of Japan*, March, 1923.

## Heat Applications and Material Handling

*Problems in Electric Furnace Operation.*—F. V. ANDREAE.—An abstract of this paper may be found in the ELECTRICAL WORLD report of the A. I. E. E. spring convention, May 5, 1923, on page 1024.—*Journal of the A. I. E. E.*, May, 1923.

*Relation Between Current, Voltage and the Length of Carbon Arcs.*—A. E. R. WESTMAN.—An account of the early work on the electric arc has been given by Mrs. Ayrton and a summary of present knowledge by Steinmetz. Each of these writers is the author of a formula connecting current, voltage and arc length; but in the experiments on which these formulas were based the currents ran up to only 30 amp. or so, and it seemed desirable to add to the experimental material. The paper under notice gives an account of measurements made with currents up to 770 amp.—*Paper presented before the American Electrochemical Society, New York*, May 3 to 5, 1923.

## Electrophysics, Electrochemistry and Batteries

*Battery Charging at the Chicago Mail Terminal.*—W. LANDESS.—Facilities are provided at the Chicago Union Station mail terminal for the charging of tractor batteries and of all batteries on mail cars in the terminal. Switching and charging panels, car-lighting charging panels, generating and switching of power and motor-generator sets are described.—*Railway Electrical Engineer*, April, 1923.

*Effect of Current Density on Overvoltage.*—M. KNOBEL, P. CAPLAN and M. EISEMAN.—There are numerous references in electrochemical literature on the effect of current density on overvoltage, but they set up in general more or less isolated values and for comparatively small current densities. The experimental conditions are so different also that it would be difficult to compile a comparable set of data. On account of the great technical importance of this phase of overvoltage, and also for the theoretical interpretation of overvoltage, it was thought desirable to have extensive and consistent data in this field. In this article the authors have attempted to include all the more common metals and alloys as cathodes and to determine oxygen and halogen overvoltages on as many electrodes as possible. While the overvoltage values obtained may not be acceptable as absolute values, they should at least be comparable as the experimental conditions were maintained alike in all cases.—*Paper presented before American Electrochemical Society, New York*, May 3-5, 1923.

## Telegraphy, Telephony, Radio and Signals

*Radio as Applied to Telephony.*—O. B. BLACKWELL.—The object of this paper is to give an idea of what radio is and what it means to the telephone business. The first part is intended to assist in forming a clear picture of the physical nature of both wire and radio transmission, while the latter part is a brief discussion of the fields of use for which radio has been developed or for which it has been considered.—*Electrical Communication* (published by the International Western Electric Company), February, 1923.

*A High-Voltage Mechanical Rectifier.*—S. T. WOODHULL.—A mechanical power rectifier for high-voltage direct-current production is described and its design and operation are discussed. This generator uses transformer action for the generation of the high voltage and a synchronous commutator for rectification.—*Proceedings of Institute of Radio Engineers*, April, 1923.

## Traction

*Roller-Bearing Tests on Railway Cars.*—During the past two years tests on two single-truck cars of the Wigan Corporation Tramways and on one double-truck car of the London County Council have been made to determine the characteristics of cars equipped with plain bearings and with roller bearings. The accompanying illustrations show the tractive resistance at various speeds and coasting-distance curves for both types of bearings. Comparison was also made between the two types as regards starting effort and retardation.—*Electric Railway Journal*, April 21, 1923.

# Sciehtific and Industrial Research

A Department Devoted to Reports of Investigations Contemplated or Completed, Research Facilities Available and Suggestions for Co-operative Work

*Conducted by* PROF. VLADIMIR KARAPETOFF, *Cornell University, Ithaca, N. Y.*

[PRINTED IN THE THIRD ISSUE OF EACH MONTH]

[When investigations which have been completed are, in the opinion of the editors, of wide enough interest to the field we serve, details thereof will be presented in other parts of this paper. Contemplated research or that which appears to have limited appeal will be only briefly reported in this section, but details may be had by communicating with the investigator or institution named in the report. Readers are referred to the department "Digest of Electrical Literature" for investigations reported in other journals. The news and engineering sections should also be followed for research reported before technical societies.]

## Research Completed

### Cables, Lead, Protection Against Beetles

Beetles which bore through lead cables and which. nevertheless, do not or cannot penetrate pure gum rubber have proved a serious problem and pest in California and many other parts of the United States. Experiments indicate that the beetle is able to penetrate any lead alloy or any poison or repellent placed on it. Probably it is able to penetrate the poisons because it does not feed as it bores through. Beef tallow, when sufficiently soft, will stick to the beetle and suffocate it, and has been used with some success on the rings which suspend the cable. Layers of friction tape impede the boring, and thin sheets of copper, zinc, or steel prevent it.—*R. D. Hartman, H. E. Burke and T. E. Snyder, United States Department of Agriculture, Washington, D. C.*

### Lubricating Oils, Petroleum, Reclamation of

By means of simple apparatus already commercially available used lubricating oil can be reclaimed and made as good as new, or even better. An investigation has shown this to be true, judging by all the commonly accepted standards. Certain changes in the oil could be detected by special tests, but it is a matter for future investigators to decide whether or not these changes are detrimental.—*Bureau of Standards, Washington, D. C.*

### Phase Sequence Indicator

Various devices have been used for some years to indicate phase rotation on polyphase circuits. Arrangements of a more or less complicated nature have been made up and used locally by various operating companies, and during the past year a manufacturer has developed a phase-sequence indicator. This is a small portable device, consisting essentially of coils operating on a single lamp as an indicator. By two trials in connecting the binding post to a polyphase circuit the phase rotation can be determined. —*Instruments and Measurements Committee of the A. I. E. E.*

### Poles, Impregnation of

Comparative experiments have been carried on concerning the open-tank method of treatment with creosote oil, using what is known as the "B" treatment, the puncture method and the closed-tank pressure method. The results indicate that better penetration can be obtained where the sapwood has been punctured before the open-tank treatment is applied. Where the puncture treatment is applied without lacerating the fiber of the pole the increased penetration will more than compensate for any small decrease in strength due to rupture of some of the other fibers.—*Overhead Systems Committee of the N. E. L. A.*

### Solder for Aluminum

A study of the various solders for aluminum showed that the best results are obtained with compositions of zinc-tin and zinc-tin-aluminum. The tensile strength of a good aluminum solder is about 7,000 lb. per square inch, for those with higher tensile strength have, in general, their temperature of complete liquation too high for soldering purposes. Most of the metals commonly used in solders, except magnesium, are electropositive to aluminum, so that any metals used in making a soldered joint of aluminum act electrolytically in the presence of moisture as positive galvanic poles, accelerating the corrosion of the aluminum. Magnesium cannot be utilized advantageously even though it is electronegative to aluminum because the metal disintegrates rapidly in the presence of moisture. Soldered joints of aluminum which are to be exposed to moisture should be protected against corrosion by a paint or varnish.—*Bureau of Standards, Washington, D. C.*

### Transformer with Nitrogen Above Oil

When arcing sufficient to cause a breakdown of the oil occurs below the oil level, exceedingly rapid internal pressures may be created by the evolution of gas. The air space above the oil level acts as a cushion until the safety diaphragm has time to act. On the other hand, the air is undesirable because it may form an explosive mixture with liberated gases. Moreover, the air causes the oil to oxidize, producing a sludge. For these reasons means have been developed for replacing the air by an inert gas such as the atmospheric nitrogen. The transformer tank is made to "breathe" through a deoxidizing compound, so that most of the oxygen contained in the air is absorbed before it reaches the space above the oil. (For details see the *Electric Journal*, 1923, Vol. 20, page 53.)—*W. M. Dann, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.*

### Welding, Suitability of Various Materials for

Strips of various materials were created with vitreous enamel which was baked by the passage of an electric current through them. The materials tested were commercially pure-iron made in a basic open-hearth furnace, copper-bearing open-hearth iron, basic open-hearth mild steel, charcoal iron, Bessemer steel and silicon steel. In all cases except the open-hearth irons the enamel contained bubbles and blisters. The iron samples produced a perfectly smooth enamel surface free from any such defects. This indicates a freedom from gas or gas-forming constituents.—*J. H. Nead and R. L. Kenyon, American Bureau of Welding.*

## In Progress or Purposed

### Fuses for Potential Transformers

Some 13,200-volt potential transformers have such a high impedance that standard high-tension fuses do not always clear a dead short-circuit on the low-tension side, occasionally causing a transformer to blow up. It is almost impossible to obtain a fuse wire strong enough mechanically which would positively clear a secondary short-circuit. It is therefore recommended that the low-tension circuit of such a potential transformer be protected with a cartridge fuse of 15 amp. to 30 amp. rating.—*A. F. Bang, Pennsylvania Water & Power Company, Baltimore.*

### Generating Stations, Artificial

Work is being done upon the representation to a small scale of the effect of two independent generating stations feeding an artificial network. With more than one generating station some method of controlling the outputs must be obtained, and we are investigating the possibilities of using phase shifters with voltage control as artificial generators. At the same time work is proceeding on the possibility of making a synchronous motor, driven by a shunt direct-current motor, which will have the characteristics of a turbo-generator when reduced to the scale upon which the artificial lines are built.—*Vannevar Bush, Massachusetts Institute of Technology, Cambridge, Mass.*

### Insulator Troubles Due to Cement

The committee is continuing its studies on high-tension porcelain insulators, with special reference to the type of cement used between units. One of the difficulties which resulted in the failure of both pin-type and strain-type insulators has been the growth of cement. Where the design of the insulator does not allow for this growth the porcelain has in many cases been ruptured. Experiments show that the percentage of growth can be considerably reduced by the use of proper kinds of cement and by the proper curing. The trouble may also be eliminated by proper design of the cemented joint to allow for such growth.—*Overhead Systems Committee of the N. E. L. A.*

### Transmission Lines, Transient Phenomena in, Experimental Study of

A study was made last winter of direct-current transients upon a smooth single-phase line. We are now working upon alternating-current transients on both the single-phase and three-phase line. This will involve first a measurement in the simple case where the current is measured at the home end and the far end of the line, either open or short-circuited. After that, the transients will be measured at different parts of the line and with different terminal conditions. An oscillograph is used in conjunction with a vacuum-tube repeater where power drawn from the line will introduce distortion.—*Vannevar Bush and F. S. Dellenbaugh, Jr., Massachusetts Institute of Technology.*

## Suggestions for Research

### Cables, Thermal Problems in

In some tests it has been discovered that the variation in the thermal resistivity of the insulation and the emissivity of the lead on two samples of cable that were supposed to be exactly alike were sufficient to cause a difference of 10 per cent in the carrying capacity of the cable if this were determined by the maximum temperature of the copper. Some English engineers include in their cable specifications a clause which requires that the thermal resistivity of the insulation should not exceed a certain specified amount. In this country we do not have sufficient information regarding the thermal resistivity of the cables as made by the several manufacturers, nor for that matter do we know the range in the cables supposedly alike turned out by any one manufacturer. —*Cable Research Sub-Committee of the N. E. L. A.* [The University of Wisconsin and the Harvard Engineering School have signified their intention to co-operate with the sub-committee in problems of this kind. It is hoped that other engineering schools will also be willing and able to help in the elucidation of these important problems.—EDITOR.]

### Corona in Air Spaces, Preventing by Metallization

The problem of designing electrical machines and equipments for the high voltages which are now becoming common is mainly one of insulation. As important as the quality of the insulation are the configuration of it and of the electrodes and the combinations of the dielectrics of different permittivities so as not to lead to high or non-uniform dielectric flux densities. In a high-voltage generator, for instance, the mica insulation, on the part of the coil inserted in the slot, is in series with an air layer in which, owing to the low permittivity of air, corona may occur. To prevent it studies were made on coils covered with a conductor, as tinfoil, which when connected to the iron of the machine short-circuits the air space. This arrangement, however, is very delicate, since the tinfoil may be destroyed during the assembling of the coils. Better results could be obtained by the metallization process recently developed by Schoop for the galvanizing of structures. The same process may be advantageously used in other cases such as giving metallic coatings to parts of built-up insulators, so as to distribute the potential.

### Corona Loss, Theory of

Peek, Townsend, Whitehead, Kunz and others have investigated the laws of corona formation between a wire and a concentric cylinder, both theoretically and experimentally. The actually observed voltage at which corona begins, as a function of the air density, pressure and the dimensions of the electrodes, has been shown to be in good agreement with the general theory of ionization by collision and sparking between parallel plates. However, the theory has not been extended to include the actual energy loss due to corona, and Peek's emperical formula is being used. An extension of the theory of ionization by collision to account for the actually observed power loss is desired.

## New York State Officials Enlightened

### Those in Charge of Action Against Constitutionality of Federal Water-Power Law Meet Federal Power Commission and Some Misconceptions Are Cleared Up

A RECENT appearance of the Attorney-General and State Engineer of New York, along with other interested New York state officials, before the Federal Power Commission has given further color to the belief that the state administration is attempting to back out gracefully from under its bill of complaint attacking the constitutionality of the water-power act. The conference is understood to have resulted in making clear to the representatives of the New York administration that the Federal Power Commission does not interpret the water-power act as strictly as is alleged in the bill of complaint. It is understood that the New York delegation admitted that the bill was in error to that extent. It also was admitted, it is said, that many limitations on the commission had been entirely overlooked in the bill, which led to a wrong conclusion as to the scope of the commission's power.

The New York delegation made much of a ruling by Mr. Taft when he was Secretary of War to the effect that the federal government's interest in water-power development was limited to its effect in improving or injuring navigation. Apparently there was failure to take into account that Mr. Taft rendered his opinion when the only federal legislation on the statute book was the general dam act.

The recapture phase of the water-power act came in for extended discussion, it is understood. New York considers itself the proprietor of the bed and banks of streams and contends that the exercise of the recapture provision of the act by the Federal Power Commission would be taking away from New York property over which the federal government has no jurisdiction. The New York delegation was advised that under the recapture phase of the act the federal government merely sets up a means of determining how recapture is to be carried out provided the United States has the authority to take over the project.

#### No Danger to Barge Canal

It also was pointed out that in so far as the Barge Canal is concerned no license could be issued covering the use of that water until the applicant could show full compliance with the state law and that the commission never has entertained any application on the Mohawk River and never would attempt to take jurisdiction over a project which would affect the water supply of the canal.

New York takes exception to the action of the Federal Power Commission in giving a preliminary permit to the Lower Niagara River Power & Water Supply Company, covering the Niagara Gorge development. How did the commission know, it was asked, that the State of New York did not prefer that the preliminary permit be given the Niagara Gorge Railway Company, whose application the Federal Power Commission rejected? The answer in that case was that the preliminary permit was granted to the Lower Niagara company before New York had set up its Water Power Commission. The Lower Niagara company presented acts of the New York Legislature granting certain franchises to that company, evidently sufficient proof to convince the commission that it had the necessary state authority to go ahead with the development. Any preliminary permit is granted with the understanding that the applicant must secure state authorization for development before the license is issued, but in cases that are at all important it is the policy of the commission to confer with the state authorities directly to ascertain their feeling toward the project.

There is every reason to believe that the conference has resulted in a material clearing of the atmosphere. Practically the only point of difference which was not eliminated at the conference was that as to the scope of the federal authority over water power. The federal government bases its authority to control floods, further irrigation and regulate water-power development on the rights over navigation granted it by the Constitution, just as it bases many activities on the interstate commerce clause of the Constitution. Since the Supreme Court has upheld many apparently far-fetched activities related to commerce, it is believed that the water-power act will be upheld as the control exercised over power development is a contractual relationship incident to the protection of the navigability of streams.

## Savings in Fire Insurance

### Through Efforts of National Electric Light Association Committee Electric Light and Power Companies Receive Lower Premium Rates

DURING the last twelve months member companies of the National Electric Light Association have received reductions in premium rates for fire insurance on electric generating and substation property amounting in the aggregate to more than the total dues paid into the N. E. L. A. treasury by electric light and power companies.

In the opinion of Charles B. Scott, chairman of the insurance committee, and S. E. Wolff, vice-chairman, this is but the beginning, as the full benefits of the movement under way will not be realized until all companies have taken advantage of the work of the committee and asserted their right to a reinspection of their properties and a revision of their rating schedules. It is said, too, that a tremendous amount of detail work remains to be done before the greatest benefits will be obtained by the industry as a whole.

At the N. E. L. A. convention in Atlantic City last year the insurance committee reported that it had arranged with representatives of the fire insurance underwriters for a revision of rating schedules applying to electrical generating and substation properties. This arrangement was brought about through the adoption of a resolution by the underwriters authorizing a reduction of not to exceed 25 per cent on all premium rates on this class of property. This reduction was to apply to the business as a whole, with the understanding that schedules would be so arranged as to reward the reduction or elimination of fire hazard through good standards of construction, housekeeping, etc., while properties whose conditions did not reflect good standards of construction with a reduction of the fire hazard were to receive a lesser benefit. This agreement made necessary the devising of new forms of rating schedules and their subsequent adoption by the several insurance rating bureaus of the country. After the arrangement of these schedules and their adoption by

SAVINGS IN COST OF CENTRAL-STATION FIRE INSURANCE UNDER NEW RATINGS

| | Amount of Insurance Carried | New Rate per $100 Value (Cents) | Annual Savings Amount | Annual Savings Per Cent |
|---|---|---|---|---|
| Alabama Power Co. | $7,731,050 | 11.4 | $2,916.61 | 25.2 |
| Helena (Ark.) Gas & Electric Co. | 210,000 | 17.8 | 90.30 | 19.5 |
| Western States Gas & Electric Co. | 418,550 | 89.4 | 1,171.94 | 24 |
| Colorado Power Co. | 529,300 | 80 | 938.00 | 17.5 |
| Pensacola (Fla.) Electric Co. | 802,000 | 49.5 | 95.60 | 5.7 |
| Georgia Railway & Power Co. | 2,270,000 | 19.05 | 647.05 | 12.5 |
| Illinois Traction System | 629,975 | 25.9 | 497.69 | 23.4 |
| Wabash Valley Electric Co | 180,000 | 16.8 | 657.00 | 37.5 |
| Iowa Southern Utilities | 319,325 | 17.3 | 1,050.58 | 31 |
| Lexington (Ky.) Utilities Co. | 200,740 | 27.7 | 664.45 | 54.4 |
| Central Maine Power Co | 2,647,475 | 125* | 3,309.68 | 23.1 |
| Consolidated Gas, E. L & P. Co. | 8,915,000 | 9.741 | 4,471.16 | 33.9 |
| Springfield (Mass.) Electric Light Co. | 780,000 | 23.59 | 396.24 | 17.7 |
| Citizens' Light & Power Co., Adrian, Mich. | 58,200 | 104.8 | 96.61 | 32 |
| Duluth Edison Electric Co. | $300,000 | 56.1 | $750.00 | 30.8 |
| Ozark Power & Water Co., Branson, Mo. | 91,000 | 103.8 | 56.42 | 5.6 |
| Nebraska Power Co. | 2,500,000 | 11.41 | 2,028.79 | 41.7 |
| Electric Light & Power Co., Hightstown, N.J. | 9,000 | 66.85 | 10.80 | 15.2 |
| Santa Fé Water & Light Co. | 49,700 | 134 | 303.17 | 31.3 |
| Genesee L. & P. Co., Batavia, N. Y. | 126,000 | 112 | 516.60 | 26.8 |
| Fessenden (N. D.) Light & Power Co. | 13,000 | 174 | 35.10 | 13.4 |
| Northern Ohio Traction & Light Co. | 4,607,645 | 17.6 | 2,395.98 | 22.7 |
| Northwestern Elect. Service Co., Erie, | 137,400 | 20.75 | 218.[illegible] | 43.4 |
| Tennessee Electric Power Co. | 1,520,138 | 34.27 | 1,378.77 | 20.9 |
| Warrenton (Va.) Electric Light & Power Co. | 36,000 | 85.48 | 57.67 | 16 |
| Natrona Power Company, Casper, Wyo. | 105,000 | 84.67 | 675.46 | 44 |

* Three years' rate.

the bureaus, reinspection of properties to which they were to be applied was necessary before the benefits could be enjoyed.

Since May, 1922, revised schedules have been put into effect throughout the United States, except in the States of Kansas, Mississippi, Texas and parts of the New England States, and have been applied generally on the properties of member companies.

During April Chairman Scott requested member companies to report the progress of reinspection work and the results obtained. He requested that replies be made in time to reach him not later than May 10, and as of that date eighty-four companies had given complete information. Under the revised rating schedules the premium savings on this insurance amount to more than $96,000 annually, or 24.3 per cent of premiums paid under the old rating schedules.

Complete data are not available, but in order to give an idea of the results generally obtained, examples were chosen at random from the states where the schedules are in effect and are printed in the accompanying table.

The committee finds that a great many central-station companies have not had reinspections of their property and seem to be unaware of their right to demand such reinspections. In other cases central-station managers seem to take little interest in the proposition and are not co-operating with the insurance interests to get the best results. Thus, while the general results are fairly satisfactory to the committee, it will, as already said, require a great deal of attention to details to reap the full benef

## Contract Let for Ouachita River Dam

A contract for the construction of the Remmel Dam on the Ouachita River between Malvern and Hot Springs, Ark., has been awarded to Ford, Bacon & Davis by the Arkansas Power & Light Company of Pine Bluffs. This dam, from which 15,000 hp. will be developed, is the first of a series of three hydro-electric plants on the Ouachita River that will eventually develop 120,000 hp. The Remmel Dam will be 60 ft. in height and 900 ft. long at the crest. The lake formed back of the dam will cover about three thousand acres of ground. The new plant will tie into the transmission system of the Arkansas Power & Light Company, which already has transmission lines within a few miles of the plant site.

## Hot Springs Central Station Little Harmed by Flood

A telegram to the ELECTRICAL WORLD from S. E. Dillon, general manager of the Citizens' Electric Company, Hot Springs, Ark., says that service was suspended for only about three hours when a flood temporarily overwhelmed that city early this week. Fire destroyed sections of the company's lines, but the loss was nominal. The water came up to the pump station, forcing the shutting down of the plant for the length of time mentioned. Street-car service was discontinued for about twenty-four hours, but newspaper accounts of conditions in the city were, Mr. Dillon says, exaggerated.

## Residence Load Building

### This and Public Education in Matters Affecting Utilities Are Leading Topics at Fort Worth

RESIDENCE load building occupied a large share of the attention of the delegates to the annual convention of the Southwestern Public Service Association, held in Fort Worth, Tex., this week. At the Commercial Section meeting on Wednesday morning it was pointed out that in spite of the efforts devoted to appliance sales the average kilowatt-hour residential sales have not increased materially. A warm discussion of the possibilities of the electric range took place in which several took the position that electric ranges are not a desirable load because of the expense in distribution equipment required to carry them and the excess transformer capacity required.

J. H. Gill of the Dallas Power & Light Company said that fears as to the effect on transformer capacity were not well grounded and that the effect on the peak loads is merely to broaden them, as experience has shown that the range peak occurs fifteen to thirty-five minutes earlier than the peak due to other evening loads. Service difficulties, he said, should not be allowed to stand in the way of range-load development as these difficulties are no greater than those involved in developing the use of any load-building devices. Mr. Gill said that the way to successful load building involved a strict control of both the commercial man and the engineer responsible for distribution system building, so that the commercial man, on the one hand, will not be allowed to scatter ranges in such a way that individual distribution equipment for each range is required and the engineer, on the other, will not to be allowed to provide equipment to meet theoretical conditions that practical experience has shown do not exist.

Care in handling transformers during installation was urged in a discussion of transformer maintenance schedules, it being shown that if linemen are allowed to grasp the leads in handling distribution transformers the bushings are damaged and a breakdown may be the consequence. The use of slings that hook into either eyes or lugs provided for lifting purposes was urged.

H. C. Abell of the Electric Bond & Share Company, New York, recounted four processes that must be gone through in building public understanding of utility problems. Utility employees must be educated to understand utility problems so that they can talk intelligently and sympathetically of them to those with whom they come in contact. The people of the community must then be brought to an understanding of the utility problems. State education along these lines must be done through general bodies like the public utility information committees, and national education must be carried on through national associations.

Dr. E. B. Shurter of the University of Texas dwelt on the value of public speaking as a means of educating the public in utility problems and their relation to community welfare. H. B. Flowers of the New Orleans Public Sei ice Company deprecated any effort at concealing facts concerning the utilities.

The convention, which included sessions of the railway and gas associations, lasted from Tuesday to Thursday inclusive, with a banquet on Wednesday and a Texas barbecue on Thursday.

# N. E. L. A. 1923 Convention Program

*(Tentative Draft Subject to Revision)*

## General and Executive Sessions

TUESDAY, JUNE 5, 9:30 A. M.

"Greetings to the Industry," Thomas A. Edison.
Address of President Smith.
Report of Treasurer Neumuller.
Report of membership committee, H. K. Mohr.
Report of Executive Manager Aylesworth.
Report of committee on constitution and bylaws, W. C. L. Eglin.
National Section reports: Public Relations, H. T. Sands; Accounting, William Schmidt, Jr.; Commercial, O. R. Hogue; Technical, R. F. Schuchardt.

WEDNESDAY, JUNE 6, 9:30 A. M.

Report of company employees' organizations committee, R. B. Grove.
Report of rural-lines committee, G. C. Neff.
Address, O. E. Bradfute, president American Farm Bureau Federation.
Report of water-power development committee, F. T. Griffith.
Address, Gen. Guy E. Tripp.
Report of Joint Committee for Business Development, E. W. Lloyd.

THURSDAY, JUNE 7, 9:30 A. M.

Report of accident prevention committee, C. B. Scott.
Report of customer-ownership committee, M. R. Bump.
Address, Dwight N. Lewis.
Report of insurance committee, C. B. Scott.
Address, Julius H. Barnes, president U. S. Chamber of Commerce.
Address, Lewis E. Pierson, chairman of board Irving Bank-Columbia Trust Co.
Report of committee on electrical resources of the nation, M. S. Sloan.
Report of memorial committee, W. H. Onken, Jr.

FRIDAY, JUNE 8, 9:30 A. M.

Report of committee on Doherty and Billings prizes, A. S. Loizeaux.
Report of wiring committee, R. S. Hale.
Address, O. C. Merrill, executive secretary Federal Power Commission.
Report of joint fuel committee, J. W. Lieb.
Report of rate research committee, Alex Dow.
Report of public policy sub-committee on inductive co-ordination, R. F. Pack.
Report of merchandising policy committee, John F. Gilchrist.
Report of lamp committee, W. W. Freeman.
Report of committee on constitutional revision.
Report of resolutions committee, W. W. Freeman.
Election of officers and members national executive committee.
Installation of president-elect.

## Technical Sessions

MONDAY, JUNE 4, 2 P. M.

Session subject: "Problems of Electricity Generation"

Address, Chairman R. F. Schuchardt.
Report of prime movers committee, C. F. Hirshfeld.
Report of hydraulic power committee, O. G. Thurlow.
Report of electrical apparatus committee (generating station portion), R. H. Tapscott.

Symposium on Steam Plant Generation, High Steam Pressures and Temperatures.

Address, Charles H. Merz, London.
Address, Fred N. Bushnell.
Address, "Pulverized Fuel for Central Station," Prof. A. G. Christie.
Address, "Useful Life of Turbines," Peter Junkersfeld.
Address (speaker to be selected).
Address, "Comparison of American and European Practices of Waterwheel Construction and Water-Power Development," H. B. Taylor, Wm. Cramp & Sons.

TUESDAY, JUNE 5, 2:15 P. M.

Session subjects: "Problems of Conversion," "Problems of Metering."
Report of nominating committee, J. C. Martin.
Election of section officers and executive committee.
Address, "The Status of the Safety Code," Thomas Sproule.
Report of electrical apparatus committee (substation portion), R. H. Tapscott.

Symposium on Substation Equipment.

Address, "Power-Tube Possibilities" (speaker to be selected).
Address, "Storage Batteries on Metropolitan Systems," Philip Torchio.
Address, "Bulk Supply to Industries," Alex Dow.
Report of motor committee, W. L. Wadsworth.

Symposium on Metering.

Address, "The Place of the Meter in Industry," F. G. Vaughan.
Address, "The Education of Metermen," F. D. Paine.

WEDNESDAY, JUNE 6, 2:15 P. M.

Session subjects: "Problems of Transmission and Distribution," "Problems of Utilization."

Report of overhead-systems committee, L. M. Klauber.
Report of underground-systems committee, G. G. Post.
Report of electrical apparatus committee (motor rules and service voltages), R. H. Tapscott.

Symposium on Transmissions of the Future.

Address, Frank G. Baum.
Address, William S. Murray.

THURSDAY, JUNE 7, 2:15 P. M.

Session subject: "Interindustry Co-operation on Inductive Co-ordination."

Committee on inductive co-ordination will stage typical negotiations between a power company and a telephone company for the co-ordination of all power and signal lines.

## Commercial Sessions

MONDAY, JUNE 4, 2 P. M.

Address, Chairman Hogue.
Report of committee on electrically equipped furniture, Ralph Neumuller.
Report of Electric Truck and Car Bureau, Charles R. Skinner, Jr.
Report of electric vehicle school committee, E. S. Mansfield.
Address, "Lowering Transportation Costs by the Use of Electric Trucks in the Warehouse Industry," Charles S. Morris.
Address, "Supervision of the Motor-Truck Equipment of New York Utility Companies," John Stilwell.
Address, "The National Increase in the Use of Electric Trucks," William Van C. Brandt.
Report of committee on commercial service and relations with customers, Harold Wright.
Report of education committee, Fred R. Jenkins.

TUESDAY, JUNE 5, 2:15 P. M.

Report of Lighting Sales Bureau, G. Bertram Regar.
Report of division on commercial aspects of lamp equipment, G. H. Stickney.
Report of sign, display and billboard lighting division, H. H. Magdsick.
Report of division on lighting of large buildings, C. C. Munroe.
Report of street and highway lighting division, L. A. S. Wood.
Report of industrial lighting division, J. Carl Fisher.
Report of residence-lighting division, M. Luckiesh.
Report of store-lighting division, James Kirk.

WEDNESDAY, JUNE 6, 2:15 P. M.

Report of Power Sales Bureau, C. K. Nichols.
Report of competitive power division, H. H. Holding.
Address, William S. Murray.
Report of industrial-heating division, Wirt S. Scott.
Address, C. F. Hirshfeld.
Report of general power division, Ernest Pragst.
Address, D. B. Rushmore.

THURSDAY, JUNE 7, 2:15 P. M.

Report of Merchandise Sales Bureau, F. D. Pembleton.
Report of division on education and training of salespeople, E. A. Edkins.
Report of sales analysis division, W. R. Collier.
Report of standardizing and testing division, R. S. Hale.
Report of division on basis of paying salespeople, H. A. Lewis.
Report of electric cooking and heating division, C. O. Dunten.
Election of section officers and executive committee.

## Public Relations Sessions

MONDAY, JUNE 4, 2 P. M.

Address, Chairman Sands.
Report of committee on employee relations with public, L. B. Herrington.
Report of committee on co-operation with educational institutions, John C. Parker.
Report of committee on manufacturers' advertising, P. L. Thomson.
Report of committee on public speaking, A. C. Marshall.
Report of Information Bureau organization committee, H. C. Abell.
Report of committee on relations with financial institutions, M. S. Sloan.
Report of women's public information committee, Miss O. A. Bursiel.
Election of section officers and executive committee.

TUESDAY, JUNE 5, 2:15 P. M.

Session subject: "State Public Utility Information Bureaus."

Address, Frank A. Munsey.
Address, Bruce Barton.
Address, George E. Lewis.
Address, "The State Committee," W. W. Freeman.
Symposium by directors and members of the state public utility information committees.

WEDNESDAY, JUNE 6, 2:15 P. M.

Session subject: "Developing Public Relations—How? Why?"

Address, M. H. Aylesworth.

Symposium from Viewpoint of State Regulatory Authorities.

Six addresses by public service commissioners (names to be announced).
Symposium from Viewpoint of Member Company Executives.
Addresses by W. E. Creed, P. S. Arkwright, S. R. Inch, W. W. Freeman, Martin J. Insull, J. F. Owens, Dwight N. Lewis and Owen D. Young.

## Accounting Sessions

MONDAY, JUNE 4, 2:15 P. M.

Address, Chairman Schmidt.
Report of committee on purchasing and storeroom accounting, J. F. Torrence.
Report of committee on accounting education, Fred R. Jenkins.
Report of committee on preservation of records, Franklyn Heydecke.
Report of filing systems committee, E. W. Kells.

TUESDAY, JUNE 5, 2:15 P. M.

Report of committee on classification of accounts and annual reports, W. J. Meyers.
Paper, "Uniform Classification of Accounts," Fred W. Herbert.
Report of committee on accounts-payable records, E. A. Davis.
Report of committee on fixed capital records, C. M. Breitinger.

WEDNESDAY, JUNE 6, 2:15 P. M.

Report of committee on security holders' records, G. B. Thomas.
Report of committee on customers' records and billing methods, B. F. McGuire.
Report on budget, D. W. Harris.
Report of payroll standardization committee, A. B. McCoard.

THURSDAY, JUNE 7, 2:15 P. M.

Election of section officers and executive committee.
Address, Carl D. Jackson.
Report of merchandising accounting committee, P. H. Myers.
Report of committee on mortgage and trust agreements, Walter C. Lang.

## Program for Swampscott

**Arrangements for Summer Convention of A. I. E. E. Are Rapidly Taking Shape**

ARRANGEMENTS for the summer convention of the American Institute of Electrical Engineers, to be held at Swampscott, Mass., on June 25-29, have taken final shape, and an excellent program has been drawn up by the committee in charge. The technical sessions will be held in the mornings; in the afternoons there will be tennis, golf, bridge and trips to points of interest, electrical, historical and other, for the delegates and the ladies accompanying them, while entertainment, dancing and special features will fill the evenings. Monday will be devoted largely to registration, though there will be a meeting of section delegates from 10 a.m. to 12:30 p.m. as well as from 2 p.m. to 4 p.m.

The technical program prepared, subject to possible changes, is as follows:

TUESDAY MORNING, JUNE 26

Address of welcome, Governor Cox.
President's address, Frank B. Jewett.
"Cable Charge and Discharge," Dr. Charles P. Steinmetz.
"Dielectric Strength Ratio Between Alternating and Direct Voltages," J. L. R. Hayden and W. N. Eddy.
"Cable Geometry and Calculation of Current-Carrying Capacity," D. M. Simons.

WEDNESDAY MORNING, JUNE 27

(Parallel Session No. 1)

"The New Weymouth Station," J. Pope.
"Cooling of Electric Machines," G. E. Luke.
"Free and Forced Convection of Heat in Gases and Liquids," C. W. Rice.

(Parallel Session No. 2)

"Electric Plant for Transoceanic Radio Telegraphy," E. F. W. Alexanderson, A. E. Reoch and C. H. Taylor.
"Electric Plant for Transoceanic Radio Telephony," O. M. Arnold and Lloyd Espenschied.
"Measurement of Frequency Over the Communication Range," J. W. Horton, Messrs. Ricker and Morrison.
"Telephone Equipment for Long-Distance Cable Circuits," C. S. Demarest.
"Electrical Loud Speaker," A. Nyman.

THURSDAY MORNING, JUNE 28

"Transmission-Line Transients," V. Bush.
"Artificial Transmission Lines with Distributed Constants," F. S. Dellenbaugh.
"General Consideration of T and Pi Artificial Lines in Connection with a Proposed Compensated Pi Line," H. Nukiyama.
"Miniature Alternating-Current Transmission Systems," O. R. Schurig.
"Proximity Effect in Wires and Thin Tubes," H. B. Dwight.
"Simplified Method of Analyzing Short-Circuit Problems," R. E. Doherty.
"The Floating Neutral," L. S. Doggett.

FRIDAY MORNING, JUNE 29

(Parallel Session No. 1)

"Quality of Incandescent Lamps," J. W. Howell and H. Schroeder.
"Art of Sealing Base Metals Through Glass," W. G. Houskeeper.
"Measuring Instrument Standards," H. B. Brooks.
"Continuous-Current Generator for High Voltage," S. R. Bergman.
"Duplication of Electric Side of Power Stations," W. F. Sims.
"Pellet-Type Oxide-Film Arrester," N. A. Lougee.

(Parallel Session No. 2)

"Gaseous Ionization in Built-up Insulation," J. B. Whitehead.
"Effect of Transient Voltages on Dielectrics," F. W. Peek, Jr.
"The Axially Controlled Magnetron," A. W. Hull.
"Photographic Study of High-Voltage Discharges," K. B. McEachron.

Among the special features of the gathering will be the president's reception on Tuesday evening; an illustrated lecture by Prof. C. E. Magnusson on Wednesday afternoon; a lecture on the "North Sea Barrage" by Capt. R. R. Belknap, U. S. N., on Thursday evening; symphony concerts by radio, and special illumination of the building and grounds at 9 p.m. on Tuesday and Wednesday.

## Arizona Still Recalcitrant

**Governor Promotes the Policy of State Control and Ownership of Colorado Projects**

ARIZONA apparently still persists in her opposition to the seven-state treaty governing the development of the Colorado River, which, it will be recalled, was defeated in the Legislature of that state, all the other six states concerned accepting it. News comes from Phoenix that on May 9 more than thirty men met with Governor Hunt and indorsed a policy of state control and eventual state ownership of all power projects developed on the Colorado within the state boundaries. This policy has been christened the "Arizona plan," and to further it Governor Hunt appointed a committee of nine men to draw up development plans.

Two plans were presented, the McGregor plan and the Greenway plan. The former looks to the immediate ownership and control of any development that may be undertaken by a non-partisan commission, state ownership to be acquired by a bond issue tentatively set at $100,000,000. The Greenway plan looks first to the ratification of the Colorado River pact and the control by the state of development works constructed by private capital, with the privilege to the state of acquiring them by purchase when they shall be found to be profitable.

Still another plan is advocated by former State Engineer Maddock under which Arizona would settle its differences with the other states of the lower basin and, by reason of the close relation existing between Arizona and California because of the Imperial Valley, California would be asked to co-operate in and participate in the expense of any development undertaken.

At Santa Barbara, Cal., on June 7-9 the League of the Southwest will hold a meeting to discuss the Santa Fé pact. Governor Sweet of Colorado has, however, announced that he will not send a representative because to do so might be construed as "interference with the exercise of the sovereignty of a sister state."

# Will Cross Main Sierra Nevada Ridge

**First Transmission Line to Do So Has Been Authorized by the California Commission—Pacific Gas & Electric and Truckee River Power Companies to Be Interconnected.**

THE ten-year contract between the Pacific Gas & Electric Company and the Truckee River Power Company reported in the ELECTRICAL WORLD for March 24, page 709, providing for the construction of the first transmission line to cross the main ridge of the Sierra Nevada Mountains separating California from Nevada has been approved by the California Railroad Commission. The Pacific Gas & Electric Company will build a 60,000-volt line from its present system to a point at the top of the mountains near Summit, Placer County, and will deliver energy there to an amount not in excess of 5,000 kw.

At this point the line will connect with a line being built by the Truckee River Power Company, which supplies light and power to Reno, Sparks, Virginia City and contiguous points in Nevada. Increased demands for power in the mining districts and the development of pumping for irrigation purposes have forced the Truckee River Power Company to augment its supply. The energy delivered over the new line is to be charged for at the regularly filed rates of the Pacific Gas & Electric Company, the Truckee River Power Company making an advance payment of a portion of the cost of the transmission line, which will be refunded by an annual discount of 20 per cent upon future bills of the Truckee River Power Company, which guarantees a minimum annual bill of $20,000.

This enterprise will mark another step in the development of interconnected systems in the Pacific and Mountain States. As ELECTRICAL WORLD readers are aware, there now exists a continuous transmission line from Albany, Ore., to the Mexican border, formed by the connection of the lines of the Mountain States Power Company operating in central Oregon, the California Oregon Power Company in southern Oregon and northern California, the Pacific Gas & Electric Company in northern and central California, the San Joaquin Light & Power Corporation in the San Joaquin Valley, the Southern California Edison Company in southern California, the San Diego Consolidated Gas & Electric Company, whose lines reach to Tiajuana, and the Southern Sierras Power Company, whose lines reach the border of Mexicali.

More than thirty steam generating plants and almost one hundred hydro-electric plants feed into this system, and their combined output is available for the combined requirements of all.

Only four comparatively small gaps in the transmission systems of the northern states remain to interrupt a continuous line from Yuma north through California and Oregon to Puget Sound and easterly across Washington and Idaho to Billings, Mont.

## Nine-State Power Survey

**Committee of Great Lakes Section, N. E. L. A., Doing Its Work on Comprehensive Scale**

INTENSIVE work on the comprehensive electric power survey of the Great Lakes area, with the ultimate object of saving millions of tons of coal and bringing an uninterrupted flow of cheap electrical energy to cities, farms and industries in nine states, has been started, according to a report made by the power survey committee of the Great Lakes Section of the National Electric Light Association. The committee has determined to confine its first recommendation to the area covered by the southeast corner of Wisconsin, most of Illinois and Indiana and the northwest corner of Ohio. Its study is designed to show where it will be most economical and most advantageous to develop electric power up to 1950, to the end that all future extensions may be made in conformity with a definite plan. The entire region which will be studied includes Wisconsin, Michigan, Illinois, Indiana and parts of Minnesota, Iowa, Missouri, Ohio and Kentucky.

"The electric supply industry is no longer a purely local business," says the report. "Large generating stations and water powers are no longer merely local or state assets. They are the resources of the entire nation. It is now economically wrong to restrict the energy derived from them within any arbitrarily chosen limits. This energy must be so distributed that it will benefit the greatest possible number of people.

"'The outstanding feature of our future development plans is to provide a common reservoir from which electricity can be drawn at any point for any purpose, be it for lighting a home, operating a factory or providing power for railroads. Not until the power for the future is made only at the most economical points, and not until every available source of power that can be economically developed is put into use, will all the people derive the full benefits of electricity.

"In the earlier years little thought was given to the advantages of ultimate interconnection. We now will plan to base all future development on growth in population and industrial expansion, accessibility to coal fields and waterways and the labor market. The general location of large and small generating stations will be determined and reasons for such location given. The general run of transmission lines will be determined, with arrangements for lines radiating through rural districts."

R. F. Schuchardt, Chicago, is chairman of the committee, of which the other members are: From Wisconsin, Prof. Daniel W. Mead, P. D. Kline and G. G. Post; from Michigan, L. B. Andrus, J. C. Parker and B. E. Morrow; from Illinois, J. P. Clayton, G. W. Hamilton, J. L. Hecht, E. S. Hight and R. B. MacDonald; from Indiana, W. D. Carr and E. G. Ralston; from Minnesota, S. B. Hood; from Iowa, C. A. Sears, and from Kentucky, L. S. Strong. H. H. Field, Chicago, is engineer-secretary.

## Pulverized-Fuel Regulations Before N. F. P. A.

No action on the tentative pulverized-fuel regulations was adopted at the annual meeting of the National Fire Protection Association, held at Chicago May 8-10, other than that the committee on dust explosion hazards agreed to draw up improved specifications which could apply particularly to modern central stations. The committee felt that while the present proposed regulations were well suited for industrial and metallurgical plants, they would, from the standpoint of insurance, place a hardship upon central-station companies now using or installing pulverized-fuel systems. The regulations were printed in the ELECTRICAL WORLD for March 24, page 697. The hazards committee is to prepare a revised code consistent with modern practice to be presented at the next annual meeting of the association.

# Nebraska N. E. L. A. Has Successful Meeting

**Papers on Public Relation Policies, Rural-Line Specifications, Electrical Merchandising and Municipal Ownership Are Well Received—Service at Cost Frowned Upon**

IN A STIRRING plea for better re lations with the public, George A. Lee, Omaha, presented the story of the utilities' growth before the nineteenth annual convention of the Nebraska Section, N. E. L. A., at Omaha on May 10 and 11. Mr. Lee pointed out three direct results of the movement for improved policies—first, the comparatively few rate cases now up for settlement; second, a deeper appreciation by company managers of the wisdom of friendly relations, and third, the growth of better feeling toward the utilities. Quoting from a Supreme Court decision which held that rate questions were now judicial and not legislative, he declared that such a sentiment was a direct face-about from the feeling ten years ago, when rulings were sometimes upheld regardless of their confiscatory features. Mr. Lee urged strongly that utility managers should go directly to their customers and present their story. Although newspaper publicity served well, he felt that a speaker out on the firing line explaining utility problems was the best mouthpiece.

O. J. Shaw, Lincoln, told of the work of the Nebraska Public Utility Information Bureau, which is printing weekly a thousand circulars for distribution throughout the state.

### RURAL LINE PROCEDURE

John C. Hoge, Grand Island, in his report on rural lines listed nine factors affecting rural practices in Nebraska. Specifications adopted in other states had been largely followed, but provision had been made for farmers who prefer to build their own lines so that a better rate can be given them. Mr. Hoge advocated a high grade of construction despite initial high cost.

F. H. Brooks, Omaha, spoke of educating the farmer to the value of electrical service as the first step in selling the energy. To indicate the growth of the rural load T. H. Fritts, Grand Island, said that in January, 1922, there were 6,417 farm lighting plants in Nebraska, while in January, 1923, this number had risen to 7,978. Since rural-line distribution losses practically equal the energy consumption, the development of more day load was strongly advocated by other speakers.

Speaking on utility service at cost, Prof. V. L. Holister, State University Engineering College, outlined three possible roads for future regulation in Nebraska—first, the present competitive status with home rule; second, state regulation; third, profit-sharing co-operation between the local utility and the community. The consensus of opinion of the convention seemed to be that "service at cost" as applied was a misnomer and that regulation by the state was the best plan of the three. K. R. MacKinnon, Omaha, explaining the power costs of the Hydro-Electric Power Commission of Ontario, said that the Canadians did not want rates based on service at cost but on the value of the service rendered.

The report of the accident prevention committee was presented by W. O. Dunn, Nebraska City, who favored instructing utility operators through their foremen and also advocated that instruction in the prevention of accidents be given in the public schools.

### SELLING ELECTRICAL MERCHANDISE

Electrical merchandising was discussed by T. E. Roach, Omaha, who explained the system used by the Union Power & Light Company. He insisted that by the proper merchandising methods no central-station company need handle appliance business at a loss. Mr. Roach has increased his average residential consumer energy consumption to 24 kw.-hr. per month with a merchandising net profit last year of 10 per cent. J. E. Davidson, Omaha, attributed success in raising his company's income per residential consumer from $16 in 1919 to $25 in 1922 to intensive merchandising and the growing popularity of the high-wattage gas-filled lamps. Regarding the necessary reserve needed to be posted against bad debts, Mr. Davidson felt that in cities where the personal equation did not enter strongly 5 per cent was none too large.

On Friday morning C. H. Talmadge, St. Louis, presented the jobbers side of merchandising. A. J. Cole, Omaha, maintained that most utility operators had "gone to seed" on merchandising, whereas this should be their most active field. F. H. Brooks and J. E. Davidson favored the policy of the central station pioneering the sale of appliances through its own organization and not letting outsiders spoil the field for future development.

J. B. Hill, Lincoln, presented a paper on municipal ownership, dealing with its causes and results and the arguments against it. He thought the Legislature should insist that every municipal plant stand on its own feet, paying all the legitimate expenses required of privately owned plants, including state and local taxes.

A report on inductive co-ordination was read by A. J. Cole dealing with the year's work of the committee.

The annual banquet was given Thursday evening at the Hotel Fontenelle, when there was a gathering of jobbers, merchants and utility men.

H. G. Taylor, chairman of the Nebraska State Railway Commission, spoke of the relation between the utilities and the commission and urged that special attention be devoted to the rural-line problem. J. E. Davidson presented the romantic side of the story of electricity and pleaded that more of this phase of the industry be put before the public. A. J. Cole, G. W. Johnstone and John L. Kennedy also spoke.

The following officers were elected: President, T. H. Fritts, Grand Island; vice-president, A. J. Cole, Omaha; secretary and treasurer, Horace M. Davis, Lincoln. The members of the executive committee will be W. B. Roberts of Omaha, G. K. Pittinger of Albion, O. J. Shaw of Lincoln, G. A. Lee of Omaha and J. E. Davidson of Omaha.

## St. Louis Is Opposed to Union Electric's Expansion Plan

Opposition to the plan of the Union Electric Light & Power Company to expend $2,000,000 in the purchase of three groups of small power plants in Missouri has been manifested by the municipal government of St. Louis, which, in a petition to the Public Service Commission against granting the company the permission it seeks, expresses the view that if the company's surplus is not needed by it in the conduct of its St. Louis business, electric rates should be reduced to a figure which will not produce such a large surplus.

In connection with the proposal, the North American Company says:

"The Light & Development Company was acquired not only for the purpose of removing existing competitive situations in the interest of continuing the best possible service at the lowest rates, but also with the view of effecting operating economies under large scale production and distribution of electric power by combination of the Missouri properties with those of the Union Electric Light & Power Company. It is in furtherance of this plan that the Union Electric Light & Power Company has applied to the Public Service Commission of Missouri for authority to take over, at the cost to the North American Company's interests, all Missouri subsidiaries of the Light & Development Company."

## United Gas & Electric Corporation Readjustment

The stockholders' readjustment committee of the United Gas & Electric Corporation, which controls electric light and power companies and other public utilities in Pennsylvania, New York and several other states and which suffered a large impairment in capital account through the foreclosure of mortgages held against the International Traction Company and the American Cities Company, has proposed to its stockholders a plan of readjustment by which a consolidation with the Berkshire Corporation, recently organized in Connecticut to acquire three electrical properties in Lancaster County, Pa., where the United Gas & Electric Corporation also has subsidiaries, is effected. If the plan is approved by the stockholders, the consolidated corporation will issue its preferred stock (of the par value of $100 a share) and its common stock (of the par value of $10 a share) in exchange for the first preferred stock of the corporation on the basis of seven shares of preferred and seven shares of common stock of the consolidated corporation for ten shares of first preferred stock of the corporation.

The total authorized capital stock of the consolidated corporation will be $9,000,000, of which $6,499,360 will consist of preferred stock and $2,500,640 of common stock.

## Great Falls of Potomac and Cacapon River Projects

Since two years have passed during which the United States Congress has taken no action on the development of power at the Great Falls of the Potomac, the priority granted by the water-power act has expired. For that reason the Federal Power Commission has announced formally that it is particularly desirous of receiving applications for the development of the Great Falls project.

An application for a preliminary permit covering this development has been made by Stinemann & Quick of Baltimore, but these applicants have not convinced the commission of their ability to finance such a large undertaking. It is believed, however, that action will be taken on this application in the near future if no applications are forthcoming from interests considered better qualified to make the development.

The project of the Cacapon Power Company on the Cacapon River, near Martinsburg, W. Va., has been found to come within the jurisdiction of the Federal Power Commission. The project involves the erection of a dam 175 ft. in height, which will provide 150,000 acre-feet of live storage.

The interests behind the Cacapon Power Company are the same as those behind the Cheat River development. This Cacapon storage will be of great value in taking care of the peak loads. This is one of the free storage sites relied upon by Major Max Tyler in his plan for the development of the Great Falls of the Potomac.

## U. S. Chamber of Commerce for State Utility Regulation

The eleventh annual convention of the United States Chamber of Commerce, held at New York City last week, passed forward-looking resolutions on the regulation of public utilities, international economic policy, immigration, transportation, the merchant marine, federal taxation, waterways, the coal industry and a number of other subjects. On public utility regulation it declared for state as against municipal regulation.

Julius H. Barnes of New York was re-elected president of the chamber, and Elliot H. Goodwin, Washington, resident vice-president. Four regional vice-presidents were elected in accordance with the new plan of dividing the country into four districts with headquarters in each. They were as follows: A. C. Bedford of New York for the Eastern States, Thomas C. Wilson of Chicago for the North Central States, Harry A. Black of Galveston for the Southern Central States, and H. M. Robinson of Los Angeles for the Western States.

## National Manufacturers Draft Comprehensive Platform

Meeting in New York City this week for its annual convention, the National Association of Manufacturers, representing fifteen industrial states, adopted tentatively a preliminary draft of a platform which will be recommended to both the leading political parties for adoption in the presidential campaign next year. This platform, which will be amplified and put in definitive shape next month by a committee including three members from each industrial state, is comprehensive, covering government and industry, taxation, transportation, immigration, the merchant marine, coal mining, foreign trade and other issues.

The repeal of the excess-profits tax and the imposition of a tax on gross final sales are favored, as are permissive consolidation of existing railroad systems where this will promote efficiency and the encouragement of foreign trade by a tariff policy framed in the light of present-day commercial conditions and a scientific revision of taxation laws. Government ownership in any form is strongly opposed.

## Silk-Mill Lighting

### Illuminating Engineers Discuss Applications of Mercury-Vapor and Tungsten-Filament Lamps

RECENT applications of mercury-vapor and tungsten-filament lamps to silk-mill illumination were discussed before a well-attended meeting of the New York Section of the Illuminating Engineering Society at Paterson, N. J., on May 11. Two papers were presented, "Silk-Mill Illumination with Mercury-Vapor Lamps," by C. F. Strebig of the Cooper Hewitt Electric Company, and "Lighting the Silk Industry with 'Mazda' Lamps," by H. W. Desaix of the Watson-Flagg Engineering Company. Before the meeting members and guests were taken through the National Silk Throwing Company, where an interesting example of mercury-vapor lighting was inspected.

High visual acuity, low intrinsic brilliancy and high diffusion are the features of the mercury-vapor lamp, declared Mr. Strebig, whose paper was presented by W. J. Winninghoss. He went on to point out that fine details which can be discerned only with difficulty under continuous-spectra light are readily distinguishable under the simple light of the mercury-vapor lamp. Actual installations of the mercury-vapor lamp in the winding, spinning, warping and weaving rooms were described.

#### Requirements to Be Met

Mr. Desaix's paper was in the nature of a report of an investigation. It was pointed out that a satisfactory system of lighting must meet the following requirements: Higher intensity on the looms than over the drives and aisles, adequate intensity for all purposes, freedom from glare both direct and by contrast. The cost of installation and upkeep must be reasonable in comparison with results and must pay a return on the investment. For winding and quilling, "RLM" steel-dome reflectors with 200-watt "Mazda C" lamps spaced on 12-ft. centers and 12 ft. high will give a general illumination of about 8 foot-candles, the speaker said—an intensity sufficiently high for ordinary purposes. In warping rooms where horizontal warpers are used each warper should be treated as an individual unit, using the "spilled" lighting principle. The luminaires should be placed over the creel, over the reed and over the beam, all centered over the width of the machine and using the lamps named above. The intensity in this case will be about 30 foot-candles on the work. In the throwing process good results will be secured by using "RLM" steel-dome reflectors with 200-watt enameled-bowl lamps spaced on centers of 16 ft. to 18 ft. and hung 12 ft. to 14 ft. from the floor. This will provide about 4 or 5 foot-candles. For dyeing rooms a prismatic-glass vapor-proof reflector globe using a 150-watt type "C" clear "Mazda" lamp was recommended. The units should be spaced in bays 10 ft. x 10 ft. and mounted 10 ft. from the floor. The illumination in this case will be about 12 foot-candles.

## First Divisional Meeting of Contractors' Society

The first of the divisional conventions to be undertaken by President James R. Strong and Director Laurence W. Davis of the Association of Electragists International is to take place at Pittsfield, Mass., on Thursday, June 14. This will be an Eastern Division meeting, including the New England States, New York, New Jersey, Pennsylvania, Delaware, Maryland and the District of Columbia. The Hotel Maplewood will be headquarters.

The morning session will be devoted to meetings of the New York State Association of Electrical Contractors and Dealers. Chairman F. A. Mott will preside. At 2 o'clock the first session of the divisional convention will begin. President Strong's address will be followed by a speech on "Selling Electrical Service," by Charles L. Edgar, president Edison Electric Illuminating Company of Boston. "Service After the Sale" is the title of a talk to be given by Miss Alice Carroll of the Society for Electrical Development. Charles L. Eidlitz, New York commissioner, will speak on "Back to Quality, Sane Costs and Fair Dealing." "Estimating and Selling the Job" will be the topic of Laurence W. Davis, director of promotion and development of the association.

## Missouri Convention to Be Held Afloat

Electrical transmission problems in Missouri and the adaptation of oil engines for small central stations will be the subjects of papers to be presented at the seventeenth annual convention of the Missouri Association of Public Utilities, to be held on board the Steamer Harry G. Drees on May 24-26. This steamer will leave at the foot of Market Street, St. Louis, at 8 p. m. Wednesday, May 23, for a trip to Peoria, Ill., and back, with a stopover at Quiver Beach on Friday, when a picnic will be held. The tentative program is in part as follows:

THURSDAY, MAY 24

*Morning.* — Presidential address, E. R. Locke; Public Utility Information Bureau report, W. H. Henby; address, "Comparison of the Public Utility Industry for the Years 1915 and 1921," J. B. Sheridan, manager Missouri Committee on Public Utility Information.

*Afternoon.* — Address, Hugh McIndoe, member Missouri Public Service Commission; address, "Application of Oil Engines for Small Central Stations," Stanley Stokes, Union Electric Light & Power Company, St. Louis.

FRIDAY, MAY 25

*Morning.*—Address, "Public Utility Problems from a Manufacturer's Viewpoint," George A. Hughes, president Edison Electric Appliance Company, Chicago; address, "Some Electrical Transmission Problems in Missouri," L. W. Helmreich and N. C. Mann, Missouri Public Service Commission.

## Stone & Webster Men Meet

### President of Firm Tells Treasurers that Public Utility Securities Grow More Stable

A FUNDAMENTAL gain in the attitude of the public toward utility questions which tends to increase the stability of the industry has come since the war, Edwin S. Webster, president Stone & Webster, Inc., declared at a convention of resident treasurers representing sixty companies under this management which was held this week at the home offices in Boston. "Up to the time of the great war," said Mr. Webster, "the development of the art had been such that rates in electric light and power companies, gas companies and street-railway companies had had a continuing downward tendency. New methods and increased efficiency in operation had enabled the companies, in spite of increasing basic costs, to give their service at a decreasing cost.

"A short time before the war," he continued, "costs were gradually rising, with the result that many of the companies were in the embarrassing situation of selling their service for a fixed sum, with no provision for taking care of the increased cost of production. At that time it was almost impossible to make the moderate increase in rates necessary, partly on account of the fact that a large proportion of the utilities were owned by a comparatively small number of people, and it was impossible to get the sympathy of the public in general for any such increase. Then came the war with the tremendous increase of cost which made a revision of the public utility rates absolutely necessary. The economic changes at that time were so great that the companies had no difficulty in proving before any fair tribunal the absolute necessity of a revision of rates, and they were able to bring about a clearer appreciation that the development of any locality and the public utility are so closely associated that neither can succeed without the other.

#### Welcome Change of Attitude

"With this improved understanding of the utility situation by the public in general came an almost unlooked-for advantage. Investors in the localities where the utilities were located began to see that their securities were desirable investments. Companies all over the country have successfully offered stocks, notes and bonds to their customers and to local investors, which has had the most desirable result of getting customers interested in the companies selling them service and has also opened up a new source of capital for extensions."

The convention was the third the organization has held and was presided over by H. B. Sawyer, treasurer of companies under Stone & Webster management. The program included thirteen addresses by resident treasurers from all sections of the country.

## Power Board Activities

**Rio Grande Project Waits on the State Department—Ambitious Plan for Cheat River**

PENDING a report from the State Department, the Federal Power Commission will grant no rights in connection with the project on the Rio Grande near Laredo, Tex., which is intended to export power for public utility use in Mexico. The Mexican authorities are understood to be anxious to have the development proceed.

A preliminary permit has been issued to the West Virginia Power & Transmission Company covering an extensive project for the complete development of the Cheat River in West Virginia and Pennsylvania. The project contemplates the ultimate development of 600,000 hp.

A license is to be issued covering Pit River project No. 3 of the Mount Shasta Power Corporation and a preliminary permit to the same company covering Pit River project No. 4.

A preliminary permit is to be extended by the Federal Power Commission to the Murtaugh Irrigation District covering a project on Snake River near Auger Falls. It is proposed to develop 16,000 hp. to be used in pumping water to two levels where the lift is 92 ft. and 155 ft. respectively. The district to be irrigated is known as the Hansen-Butte project. Engineers express some doubt as to the feasibility of the higher lift and point out that it probably would be to the advantage of all concerned were the power purchased from the public utility company which is operating in that region.

Preliminary permits have been issued to P. B. Cross of San Francisco, covering a small project on Deer Creek in Tehama County, Cal.; to Kehoe, Hanson, Hummel & Sutherland, covering a 200-hp. mining project on Thumb Creek, near Hyder, Alaska, and to Blue & Traversy of Hyder, covering a small project on the Soule Glacier River.

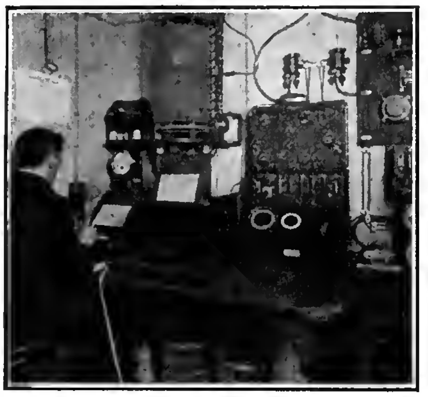
Preliminary permits extended to Maurice D. Leehey and to John H. Hughes have been revoked. In the case of the Hughes permit the provisions prescribed were not carried out. The Leehey permit, which covered an important project at Beaver Falls, near Ketchikan, Alaska, was revoked because the applicant declined to accept the terms under which the Forest Service will sell timber to be used in the manufacture of pulp.

## Predicts Reductions in Cost of Making Electricity

General reductions in the cost of the production of electricity were prophesied by C. C. Perry, president of the Indianapolis Light & Heat Company, in addressing the Commercial Section of the Indiana Electric Light Association in Indianapolis on May 3. "The keenest brains in the world are evolving intricate machines which ultimately will reduce the cost of the production of electrical energy to the minimum," declared Mr. Perry. "We must look forward to cheaper rates to the consumer. These machines will enable us to do just that. Although it may take many years, I have little doubt that we are steadily approaching the time when the consumer cannot claim he suffers the brunt of the cost of development."

## Brief News Notes

**Ocean Steamer Has Two-Way Radio.**—On the last voyage of the White Star liner Majestic radio messages were exchanged with shore stations of the Radio Corporation of America at speeds of more than eighty words per minute when the vessel was a thousand miles at sea. In order to effect two-way high-speed telegraphic service on the vessel



it was equipped by the Marconi Company with a high-speed receiver which worked most satisfactorily. High-speed signals were also received from Paris at a distance of 800 miles at a speed of eighty words per minute. The photograph showing part of the radio equipment of the steamer was supplied by the Radio Corporation of America.

**San Joaquin Corporation Has Profitable Year.**—The San Joaquin Light & Power Corporation, operating in Fresno, Bakersfield, Merced, Taft and vicinity, reports to the California Railroad Commission for the year 1922 that its electric operating revenue was $5,892,578 and electric operating expenses $3,062,172, giving a net electric operating revenue of $2,830,406. The company declared dividends of $766,800 during the year, leaving an accumulated surplus at the end of the year of $2,637,451.

**Industrial Teachers' Scholarships.**—The State of New York is offering twenty-five industrial teachers' scholarships of $1,000 each to qualified persons who have had at least five years of all-round experience of journeyman grade in one of twelve trade, industrial or technical occupations, including electrical constructing, repairing and operating and electrical drafting and design. Persons selected to hold these scholarships will spend one year at the Buffalo State Normal School preparing to teach their subjects in the public vocational schools of the state. The State Department of Education, Albany, will furnish detailed information.

**Survey of Uintah Basin.**—A survey of streams in the Uintah basin for the purpose of land classification and determination of power possibilities will be conducted about July 1 under the direction of Ralf R. Woolley, hydraulic engineer of the United States Geological Survey. Dam sites will be mapped, and final results will be included in the standard topographic map of the United States.

**Progress of Water-Power Development in Austria.**—At the present time about one thousand water-power stations are under way in Austria. In 1921 more water-power stations were under way than the entire country possessed previously. In 1922 ten stations with a combined capacity of 22,610 hp. were put in operation, while on twenty-nine plants with a combined capacity of 205,850 hp. work was continued and eight plants, rated together at 33,030 hp., were started. Altogether this came to forty-seven water-power stations with a combined capacity of 261,490 hp. To this must be added 895 smaller stations. A great saving in coal imports is hoped for when all these projects are completed.

**Progress on Wilson Dam.**—Work on the Wilson Dam at Muscle Shoals is 40 per cent complete. Progress is following the preliminary estimate closely. In March 34,586 cu.yd. of concrete was put in. Of that amount, 17,293 cu.yd. went into the dam and 17,097 cu.yd. into the power house. The remainder was put in the lock. Reports so far received for work in April indicate that the same rate was maintained. Working conditions throughout the season have been particularly favorable. There has been no trouble with high water, the only delay having been a few days when the rainfall was sufficiently heavy to interfere with work. There have been no troubles in securing labor or materials.

**Maplewood, Mo., Opens "White Way."**—The city of Maplewood, Mo., a suburb of St. Louis, opened a new "white way" on April 30 with a celebration which lasted for a whole week. This "white way" consists of 150 250-cp. series incandescent lamps mounted on ornamental iron standards placed from 50 ft. to 80 ft. apart on both sides of Manchester Avenue for a distance of three-fourths of a mile. The electric service is supplied by the Western Light & Power Company, and the lights are so arranged that 120 of them burn from dusk to midnight and thirty from dusk to daylight. The Maplewood Merchants' Association contracted for the "white way" for ten years, and the property owners have guaranteed payment of the bills.

**Largest and Fastest Cable.**—Plans for laying a new cable between New York and London by way of Nova Scotia and the Azores are announced by the Postal Telegraph-Commercial

Cables System. The new cable, contracts for the manufacture of which have already been completed, will be the largest and fastest ever laid in the Atlantic Ocean, President Clarence H. Mackay states. Engineers who designed the cable estimate that its speed will be about 600 letters per minute. The conductor will require an average of about 1,100 lb. copper per mile, as against an average of about 700 lb. per mile in the heaviest cable now in use. It will cost between $10,000,000 and $15,000,000 and is expected to be in place by Aug. 1.

**Boston Suburban Utilities Change Rate.**—Following protracted hearings before the Massachusetts Department of Public Utilities on petitions brought against the Malden Electric Company and the Suburban Gas & Electric Company, an agreement has been reached whereby the former service charges of these companies will be superseded by a three-part rate in which the first 15 kw.-hr. per month will be billed at 10½ cents net, all energy consumed above this at 8 cents per kilowatt-hour, and a minimum charge will be made ranging from 50 cents net per month for each 15-amp. meter or under to $1 net per month for each 600-amp. meter or over. The service charge under the old rate was 35 cents per month, with a 9-cent energy rate.

**Kelso-Wurdack Company Will Take Over Some Services of Light & Development Company.**—The Kelso-Wurdack Company, a Missouri corporation with offices in St. Louis, organized to manage, own and operate utility and other companies, will, it is announced, render all services that have been previously performed by the Light & Development Company of St. Louis in connection with the operating, engineering, management and current legal affairs of the following subsidiaries of the United States Public Service Company; Mitchell (S. D.) Power Company, Texas Utilities Company, Slaton (Tex.) Power & Light Company, Monmouth (Ill.) Public Service Company, Paris (Ky.) Gas & Electric Company, Danville (Ky.) Light, Power & Traction Company, and Carlisle (Ky.) Electric Light & Power Company.

**Plant to Develop 105,000 Hp. at Oak Grove, Ore.**—As plans of the Portland (Ore.) Railway, Light & Power Company develop for the construction of its Oak Grove hydro-electric project, it is foreseen that the ultimate power available will be 105,000 hp., instead of 100,000 hp., as originally figured. The total cost of the development will be $12,000,000, or $2,000,000 more than contemplated. With the approach of summer construction work is progressing rapidly on the first unit, which will develop 25,000 hp. Work is being rushed on a 25-mile extension of railroad in order that material may be transported to the dam and power-house sites. A force of 1,800 men is now engaged on the various phases of the work. It is expected that the first unit will be completed and in operation during the early part of 1924.

**Yadkin River Company Acquires Municipal Plants.**—The Yadkin River Power Company, a subsidiary of the Carolina Light & Power Company, with home office at Raleigh, N. C., has established service at Dillon, S. C., and has taken over the municipal plant. For several months the company has been engaged in the construction of a transmission line between Maxton, N. C., and Marion, S. C. This line has now been completed as far as Dillon. The municipal plant at Rowland, N. C., has already been taken over by the Yadkin company, and the municipal plant at Latta, S. C., will be acquired as soon as the transmission line is completed to that point.

**Rapid Growth of Sheboygan Plant.**—Extensive improvements and additions to cost in the neighborhood of $200,000 will be made in Sheboygan, Wis., by the Eastern Wisconsin Electric Company, operator of electric light and power and street-railway properties in that city. This expansion plan covers the purchase of additional ground and the erection of new units in its present steam generating plant which alone will cost about $180,000 and outstrip the capacity of any other steam generating plant in that part of the state. It is estimated by officials of the company that this equipment will be ready for service by Sept. 15. When completed this plant will transmit power clear across the state as far west as Fond du Lac and southwest into Illinois at Galena. The output of the Sheboygan plant for the year ended April 1, 1923, was 24,202,466 kw.-hr., an increase of 545 per cent in ten years.

# Associations and Societies

**New York Electrical League.**—Charles L. Eidlitz, commissioner for the electrical contractors' associations of Greater New York, will address the luncheon of the New York Electrical League at the Hotel Astor on Wednesday, May 23, at 12:30 p.m.

**Philadelphia Electrical Contractors' Association.**—Application for a charter has been made by this association, of which Charles E. Tull is president and M. G. Sellars secretary. The object of the association is to distribute technical electrical information, promote better trade relationships and advance the standing of electrical merchandise and workmanship.

**American Society for Testing Materials.**—The twenty-sixth annual meeting of this society will be held on June 25 to June 29, at Chalfonte-Haddon Hall, Atlantic City, N. J., with a very full program of committee reports and papers on tests, fatigue, corrosion, preservatives, magnetic analysis and so forth of various materials. F. M. Farmer, chief engineer Electrical Testing Laboratories, New York City, will report as chairman of the committee on electrical insulating materials, and there will be papers on electrical insulating varnishes, electrical slate and other topics of interest to the electrical industry.

**Public Utilities Advertising Association.**—This association, organized last fall, will hold its first session in connection with the annual convention of the Associated Advertising Clubs of the World at Atlantic City, June 3 to 7. The Public Utilities Advertising Association, which is rapidly growing, includes representatives of electric light and power, electric railway, gas and telephone companies in its membership. The sessions at Atlantic City will be devoted to public relations and utility advertising. On June 5 there will be addresses by J. C. McQuiston, manager publicity department Westinghouse Electric & Manufacturing Company, on "Why Advertise?" by Francis H. Sisson, vice-president Guaranty Trust Company, New York, on "Public Utilities and Public Relations," and by W. H. Hodge, manager advertising department, Byllesby Engineering & Management Corporation, Chicago, on "Customer Ownership Advertising."

## Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

Electrical Supply Jobbers' Association—Executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

Missouri Association of Public Utilities—River boat from St. Louis to Peoria, May 24-26.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

Westinghouse Agent-Jobbers' Association—Hot Springs, Va., May 28-June 2.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

California State Association of Electrical Contractors and Dealers—Dorner Lake, Cal., June 9-16.

Electric Power Club—Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

North Central Division, N. E. L. A.—Minneapolis, June 20-22. H. E. Young, Minneapolis General Electric Company.

Society for the Promotion of Engineering Education—Ithaca, N. Y., June 20-22. F. L. Bishop, University of Pittsburgh.

Canadian Electrical Association—Montreal, June 20-23. Louis Kon, 65 McGill College Ave., Montreal.

American Institute of Electrical Engineers—Annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

American Society for Testing Materials—Atlantic City, June 25-29.

Iowa Section, N. E. L. A.—Mason City, June 26-29.

Associated Manufacturers of Electrical Supplies—New London, Conn., June 26-29. Frederic Nicholas, 30 East 42d St., New York.

National Council Lighting Fixture Manufacturers—Buffalo, June 26-28. C. H. Hofrichter, 233 Gordon Square Bldg., Cleveland.

Northwest Electric Light and Power Association—Seattle, June 27-30. G. E. Quinan, 204 Electric Bldg., Seattle.

Ohio Electric Light Association—Cedar Point, July 10-13. D. L. Gaskill, Greenville.

New England Division, N. E. L. A.—Swampscott, Mass., Sept. 6-8. Miss O. A. Bursiel, 149 Tremont St., Boston.

Association of Iron and Steel Electrical Engineers—Buffalo, Sept. 24-28. J. F. Kelly, 513 Empire Bldg., Pittsburgh.

## Recent Court Decisions

**Telephone Company Permitted to Recover from Light Company Sum Paid Under Workmen's Compensation Act.**—The Appellate Court of Indiana has sustained a verdict permitting the Home Telephone Company to recover from the Wabash Water & Light Company sums paid and to be paid by the telephone company under the workmen's compensation act because of the death from electric shock of a lineman in its employ. The lineman while working on the telephone wires came into contact with a 2,300-volt wire maintained on the same pole by the electric service company and was killed. The telephone company, claiming that the wire with which the lineman came into contact was insufficiently insulated, sued to recover the amount it was legally bound to pay the victim's heirs, charging the defendant company with negligence. (138 N. E. 692.)*

**Kansas Court Affirms One-Dollar Service Charge.**—A service charge of $1 a month made for gas by the Leavenworth (Kan.) Light, Heat & Power Company was overruled as excessive by the Kansas Public Utilities Commission and a charge of 55 cents substituted. A temporary injunction against the enforcement of the reduction was obtained by the company, a fund being established by it for the reimbursement of its customers should the final decision sustain the commission. The Kansas Circuit Court of Appeals has sustained the company's contention that a charge of less than $1 would be non-compensatory as failing to cover the cost of installation and repairs of piping and meter, keeping accounts, rendering bills and the other items independent of general operating and maintenance expense.

**Damage to Land by Seepage from Reservoir Question for Jury.**—In Bijou Irrigation District vs. Cateran Land & Live Stock Company, an action to recover for damages to land caused by seepage from defendant's reservoir, the Supreme Court of Colorado held that where engineer witnesses for both sides testified that the source of some of the water on plaintiff's land was defendant's reservoir the question of damages was for the jury. The court found that it was improper to plead that damages were caused by high water in the river, heavy rains and seepage from a ditch other than defendant's, because such matters were merely evidential tending to show that the damage to plaintiff's land was not due to percolation or seepage from defendant's reservoir and so to support defendant's denials. Quotation of this plea was not, however, prejudicial where the court in addition stated the denials on which the defendant relied. Evidence that damages to plaintiff's land could have been averted by drainage was improperly stricken out on the ground that feasibility of drainage had not been pleaded, since the evidence went to negative the amount of damages, was not in confession and avoidance, and it would have been improper to plead it because it was mere evidence. Judgment for the plaintiff was reversed and a new trial ordered. (213 Pac. 999.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

## Commission Rulings

**Revaluation Figure for Alabama Power Company Placed at $29,000,000.**—The revaluation case of the Alabama Power Company (see ELECTRICAL WORLD, May 5, page 1057) has resulted in the Public Service Commission of that state establishing the value of the company's properties for rate-making purposes at $29,000,000, a reduction of $4,843,252 from the valuation of $33,843,252 placed by B. H. Cooper and S. P. Gaillard, associate commissioners, shortly before they retired from office. In reaching the new valuation the commission considered the evidence submitted in the original hearing and made new investigations into the various phases of the case. The valuation covers all property of the company as of June 30, 1920, the date involved in the original proceeding. To this value was added that of property acquired since that time, including the utilities of Montgomery, the utilities at Selma, the development at Mitchell Dam and other small plants. The new valuation is about $15,000,000 less than the final valuation placed by Hagenah & Erickson, engineers, who made an inventory and appraisal of the property for the commission after the valuation case was docketed in 1920. Hagenah & Erickson's original report placed the valuation at approximately $47,000,000, but conferences between them and I. F. McDonnell, engineer for the commission, caused a reduction of the valuation to approximately $44,000,444. Mr. McDonnell made a check of the valuation recommended by Hagenah & Erickson and of the valuation of Morris Knowles, who was employed by large consumers of power, and his recommendation to the commission was the establishment of the valuation at $29,000 000. Up to this time Mr. McDonnell had never made a recommendation, according to members of the commission. The total valuation includes $1,500,000 as working capital and $3,750,000 as going-concern value. Before the valuation can become final sixty days must elapse, and during these sixty days any citizen of Alabama may, under a law passed by the last Legislature, protest against the tentative valuation and may appear before the commission for the purpose of showing why the valuation should not become final. If no protest is filed within the sixty days, the tentative valuation will become final for rate-making purposes.

**Sale by Merged Corporation.**—A public utility company created by a merger is not authorized by the Pennsylvania statutes to sell and transfer to another company rights, franchises and privileges in the territory of the merged corporation which were formerly vested in a constituent company, according to a decision of the Pennsylvania Public Service Commission *in re* Topton Electric Light & Power Company.

**Bills for Separate Installations of Same Customer Must Not Be Added and Discounted.**—The Illinois Commerce Commission has overruled a rider in a rate schedule (*re* Produce Terminal Corporation) which provided that if any consumer owns several places of business in different locations and shall use electricity furnished by the company exclusively in all his places of business, he shall be entitled to a discount of 5 per cent from the total of the net monthly bills where two premises only are served and an additional 1 per cent for each additional place of business covered by the contract, the total discount not to exceed 20 per cent. Such a contract, the commission insists, is discriminatory, as for all practical purposes installations of the same customer in different localities are the same as installations of separate and individual customers.

**Going-Concern Value Should Be Shared with Public.**—The Public Utilities Commission of Connecticut in arriving at a valuation of the Ansonia Water Company made the following observations concerning going-concern value: "In determining the value of private property, such as mercantile or manufacturing establishments, the actual market value, what a willing or even anxious purchaser would be willing to pay, is an important factor and necessarily takes into consideration good will or going value of a successful business; but if market value should be considered as the measure of fair value of a utility company, upon which to base a return, many utility companies in operation today would be deprived of a fair return on the actual investment. Where a utility property is valued on the basis of cost to reproduce new, less depreciation, and the items of organization expenses, interest and taxes during construction, etc., are taken into consideration and included, and the subsequent business development cost charged to operating expenses, the intangible items of 'going value' or 'good will' should not then, in our opinion, be arbitrarily added as elements of value. . . . Whatever the intangible value of this element may be, it should, to some extent, accrue to the benefit of the public which assisted in creating it as well as to the company in increased volume of business."

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## Dr. B. B. Brackett Leaves State College

Dr. B. B. Brackett, who has been the head of the electrical engineering department at South Dakota State College for the past fourteen years, has resigned from the faculty to become head of the electrical engineering department at the University of South Dakota. Before going to South Dakota Dr. Brackett was for some time private assistant at Johns Hopkins University to Prof. Henry W. Rowland, recognized as one of the greatest physicists America has ever produced. He also held chairs of electrical engineering at the Clarkson Institute of Technology at Potsdam, N. Y., and at Rutgers College. Heretofore Dr. L. E. Akeley has not only acted as dean of the College of Engineering of the University of South Dakota but has also performed the duties of professor of physics and electrical engineering. The need of assistance in his work has been apparent, and with the addition of Dr. Brackett to the faculty he will be relieved of the work in electrical engineering and enabled to give his entire time to his other duties.

**Harold F. Eastman,** who has been associated with the Connecticut Power Company, a Stone & Webster property, has been transferred to Boston in the division of construction and engineering.

**L. P. Perry,** vice-president and treasurer of the Central Connecticut Power & Light Company, has joined the organization of the Central Hudson Gas & Electric Company, with headquarters at Poughkeepsie, N. Y.

**Wilfred G. Parkinson** of the Carnegie Institution of Washington sailed on May 3 for Santa Teresa en route to Huancayo, Peru, where the institution has an observatory in which changes in the earth's magnetism and variations of atmospheric electricity are watched.

**John E. Loiseau,** for eight years secretary-treasurer of the Montgomery (Ala.) Light & Water Power Company, has been appointed secretary of the Denver Gas & Electric Light Company. Mr. Loiseau's appointment fills the vacancy created when Clare N. Stannard was promoted to the vice-presidency and general managership upon the death of William J. Barker.

**C. E. Oakes,** an electrical engineer who has been in the service of the Federal Power Commission, has resigned to accept a position with the Pennsylvania Power & Light Company. The vacancy created by his resignation has been filled by the appointment of N. B. Keeler. Mr. Keeler for many years has been an assistant engineer of the Corps of Engineers of the army. It was he who made a recent inventory for the Federal Power Commission of the properties of the Niagara Falls Power Company.

## L. O. Ripley Heads Middle West Division of N. E. L. A.

L. O. Ripley, vice-president of the Kansas Gas & Electric Company, was recently elected president of the Middle West Division of the National Electric Light Association. Mr. Ripley, though a native of New York, has been in Kansas since 1909, when he became associated with the American Power & Light Company and was immediately sent West as the field executive of the Kansas Gas & Electric Company, which is controlled by the American Power & Light Company. He entered the electrical industry during his high-school years, when he worked in the electric light plant at Cooperstown, N. Y., in the early mornings and afternoons. Following his graduation in 1900, from Union College, Schenectady, as an electrical engineer, he engaged in outside construction work until 1903, when he returned to Schenectady and joined the Schenectady Railway Company, which at that time also operated the electric light and power business as well as the gas business in Schenectady. This property was directly affiliated with the General Electric Company. Mr. Ripley was made superintendent of light and power, which included the interurban and city railway systems as well as light and power distribution in the city. When the railway systems were sold he became manager of the Schenectady Illuminating Company and remained there until he allied himself with the American Power & Light Company. Mr. Ripley has been an important factor in utility development in Kansas, both as an executive of the light and power company with which he is associated and as an active participator in the organization and work of the division of the National Electric Light Association which he is now called upon to head.

L. O. RIPLEY

**T. C. Martin** is now secretary of the New York Electrical Society, succeeding the late George H. Guy.

**Charles W. Tippy** of Jackson, Mich., general manager of the Consumers' Power Company, was recently elected president of the Great Lakes Geographical division of the National Electric Light Association. He succeeds Harry Reid of Indianapolis.

**Howard T. Spaulding,** who has been associated with the Nela Park laboratories at Cleveland for the past fourteen years, has been appointed illuminating engineer for the Bryan-Marsh Lamp Division with headquarters in Boston.

T. S. Saylor, formerly of the appliance department of the Salem (Mass.) Electric Lighting Company, has been appointed sales manager of the Rockland Light & Power Company, Nyack, N. Y., and of the Rockland Electric Company, Ramsey, N. J.

**L. F. Wiegand,** formerly executive in charge of the investment department of the Iowa Railway & Light Company, Cedar Rapids, has been appointed assistant vice-president in charge of investments of the Central Indiana Power Company, Indianapolis, and the Indiana Electric Corporation, which is controlled by the Central Indiana Power Company.

**Col. Eugene J. Spencer,** secretary of the St. Louis Electrical Board of Trade, was officially presented with the distinguished service medal, which was awarded to him about a month ago, by Major-General George B. Duncan, commander of the Seventh Corps area, at ceremonies held at Jefferson Barracks on Friday afternoon, May 11. Colonel Spencer received his award for "meritorious and distinguished services" while in command of the Engineer Corps in the southern area of France in 1918.

E. J. Steinberg, resident engineer in Milwaukee for the Wisconsin Railroad Commission for the past ten years, will resign June 1 to ally himself with the Milwaukee Electric Railway & Light Company. Mr. Steinberg joined the commission engineering force in 1910. Three years later he was transferred from Madison to Milwaukee as resident engineer. Since then he has had charge of street-car schedules for the Milwaukee Electric Railway & Light Company and has performed other administrative and regulatory duties, involving public utility properties in the Milwaukee district.

**Edgar M. Blessing** and **Glenn Vanauken** have been reappointed for four-year terms on the Indiana Public Service Commission.

**E. C. Davis**, formerly with the merchandising division of the Westinghouse Electric & Manufacturing Company at East Pittsburgh, Pa., is now in the Los Angeles office of that company.

**Thomas F. McDonough** is now in charge of the Northwest territory of the Benjamin Electric Manufacturing Company. He will have supervision over the States of Montana, Idaho, Washington and Oregon.

**James W. Armour** has been appointed assistant general superintendent of the Murphy Iron Works plant of the Sanford Riley Stoker Company, at Detroit. Mr. Armour entered the plant in 1919 as inspector and later became production manager.

**E. L. Doty**, district service manager of the Buffalo branch office of the Westinghouse Electric & Manufacturing Company, has been appointed engineering assistant in the service department, with headquarters at East Pittsburgh. J. A. Atkinson has been appointed Buffalo service manager.

**Maurice Metcalf** of New York has been elected treasurer of the American Bosch Magneto Corporation of Springfield, Mass., and will soon assume the duties of the office. Mr. Metcalf succeeds George A. MacDonald of Springfield, who continues as a director and vice-president of the corporation.

**George F. Murphy**, formerly manager of the Pittsburgh office of the Heine Boiler Company, St. Louis, has been placed in charge of the New York territory of the company upon the retirement of Paul H. Brangs, who had been for many years in charge of the local office. Mr. Murphy will be assisted by J. L. Daly and G. A. Knowles.

**Rodney Q. Selby** of Des Moines has been appointed assistant director of the Iowa Committee on Public Utility Information. Mr. Selby goes to this committee from the Des Moines *Capital*, with which he has been associated for a number of years. He is a graduate of Drake University and has had many years' experience in the newspaper business.

**George Baily**, supervisor of distributing agents of the Westinghouse Electric & Manufacturing Company, has been elected president of the Varney Electrical Supply Company of Indianapolis, Ind. Mr. Baily became associated with the Westinghouse Electric & Manufacturing Company in 1914 as manager of the supply division of the Cincinnati office, where he remained until 1917, when he joined the Engineer Officers' Training Camp. On being mustered out of the military service in 1918 Major Baily returned to the Cincinnati office. In 1920 he was made assistant to the manager of the supply department and was transferred to the East Pittsburgh offices of the company. In 1922, when the merchandising department of the Westinghouse company was organized and the supply department reorganized, he was promoted to be supervisor of distributing agents, which position he held until his present appointment.

# Obituary

**John M. Egan**, formerly president of the Metropolitan Street Railway of Kansas City and the Kansas City Light & Power Company, dropped dead at Amboy, Ill., on May 9. He was seventy-five years of age and was born in Springfield, Mass. Mr. Egan retired from the presidency of the Kansas City companies in 1916.

**Prof. Louis Derr** of the Massachusetts Institute of Technology, Cambridge, died at Brookline, Mass., May 10, after a few weeks' illness. Professor Derr was well known in New England electrical engineering circles for his work in physics and photography. He was born in 1868 at Pottsville, Pa., and was educated at Amherst College and the Massachusetts Institute, becoming professor of physics at the latter in 1909. At the time of his death he was professor of applied optics and photography.

**William Shreeve Doran**, president of the Alberger Pump & Condenser Company and of Charles Cory & Son, Inc., New York, died on Saturday, May 12. Mr. Doran was born in Philadelphia and obtained his early training with the Southwark Foundry & Machine Company, in that city, and the United Gas Improvement Company. In 1887 he entered the employ of Henry R. Worthington and in 1900 became affiliated with the British Westinghouse interests in establishing their branch offices and supervising sales. He severed his connection with the Westinghouse company to join the Allis-Chalmers company as manager of the power department. Since 1905 he had been with the Alberger company, first in its sales department, later as vice-president and general manager and since 1918 as president. In 1920 he was elected president of Charles Cory & Son, Inc.

**Henry Woodland**, secretary and treasurer of the Allis-Chalmers Manufacturing Company and a widely known Milwaukee business man, died suddenly early on May 14. When the Gates Iron Works of Chicago was consolidated with the Allis-Chalmers Manufacturing Company, in 1901, Mr. Woodland, who was then treasurer of the Gates company, became assistant treasurer of the Allis-Chalmers company. Mr. Woodland went to Milwaukee in 1904, when the general offices of the Allis-Chalmers company were transferred there. Soon after he was made treasurer of the company and in 1916 was elected secretary and treasurer. He was also vice-president and a director of the Hanna Engineering Company, Chicago.

**Paul Preston Haynes**, a member of the Public Service Commission of Indiana under the Goodrich administration and since then an attorney specializing in utility matters in Indianapolis, died May 9 at Boston, after a brief illness, at the age of thirty-five. Mr. Haynes completed a two-year term on the commission and then was reappointed for another term by Governor Goodrich, but he resigned in March, 1921, after three years' service. Besides his work on the commission he was a member of the special war committee of the National Association of Utility Commissioners, which dealt with many important questions of railroad and utility regulation during the war.

**Rex C. Starr**, a prominent Pacific Coast engineer, was found dead on May 3 in a canal of the Merced (Cal.) Irrigation District. Mr. Starr was chief engineer and executive head of the Merced Irrigation District, a member of the firm of Thebo, Starr & Anderton consulting engineers of San Francisco, and consulting engineer for the San Joaquin Light & Power Corporation. Mr. Starr had been connected with many important power developments on the Pacific Coast during recent years. He was resident engineer for Stone & Webster on the construction of the Snoqualmie Falls plant of the Puget Sound Power & Light Company and later on the White River plant of the same company. He was assistant engineer on the construction of the Big Creek development of the Pacific Light & Power Corporation and chief engineer on the Kerckhoff and Kern River projects of the San Joaquin Light & Power Corporation. When he became associated with the Merced Irrigation District a year ago he was retained as consulting engineer by the San Joaquin Light & Power Corporation. Mr. Starr was thirty-eight years of age.

**Prof. Arthur Gordon Webster** of Clark University, an eminent physicist, died from self-inflicted bullet wounds on May 15. This tragic occurrence, which means a great loss to science, caused amazement among Professor Webster's friends and associates, for he had shown no signs of depression and must, it is believed, have taken his life as the result of a sudden impulse. He had attained great success in many scientific lines and was recognized as one of the world's greatest authorities on electricity and sound. He was born in Brookline, Mass., was graduated from Harvard in 1885 and later studied in Paris, Berlin and Stockholm. After spending a year as instructor at Harvard, he entered the service of Clark University, where he was successively docent in physics, assistant professor of physics, professor of physics and director of the physical laboratory, holding the last-named offices at the time of his death. Professor Webster was the author of several important works on electricity and dynamics and during the war was made a member of the Naval Advisory Board of Scientists, of which Thomas A. Edison was chairman. All who knew him will mourn the loss of a steadfast friend and a delightful personality, and the electrical industry will sadly miss the fruits of his brain and the enthusiasm he inspired for scientific research.

Devoted to the Discussion of Business and Economic Problems of the Producer and Distributor, with Market Reports, Trade Activities, Foreign and Construction News

## The Reduction of the Jobbing Line

### The Position of the Manufacturer Toward Elimination of Excess Varieties—What the Jobber Can and Should Do to Help the Situation

By W. I. Bickford
Secretary and Treasurer Iron City Electric Company, Pittsburgh

THE Electrical Supply Jobbers' Association meets next week for its annual summer convention in Hot Springs, Va. One of the chief topics of discussion will be the need for the elimination of excess varieties in the jobbing line. Committees of the association have been studying this problem and will come to the meeting prepared to make definite recommendations for the practical simplification of the different commodity lines. With this in mind these expressions from one of the leading electrical jobbers are of interest.

ALTHOUGH one of the leading manufacturers has "taken the bull by the horns" and taken steps to eliminate the duplicate, slow-moving and obsolete items in the so-called schedule lines of his particular manufacture, there appears to be a lack of initiative on the part of other schedule manufacturers to take similar decisive action. These manufacturers acknowledge that many items now listed can be eliminated with resulting economy to all branches of the industry affected, but there seems to be more or less hesitation on the part of the individual manufacturer to reduce the number of items in his line for fear that he may lose business to competitors who do not take similar action.

#### A Legal Aspect

It has been suggested that such manufacturers get together and follow the suggestion of the United States Department of Commerce in other lines of industry for the simplification of their line. A study made by individual jobbers of the movement of specified lines in specified territories does not show the national demand for any article now listed. However, studies of sales of the different items by individual manufacturers and the comparison of such studies at a conference of such manufacturers would show beyond question what items now made which may be slow-moving or obsolete could be eliminated.

According to Judge Debevoise, there is a legal question as to whether these manufacturers can agree between themselves to eliminate such items. It would seem that if anything definite is to be accomplished it will be necessary to arrange a conference of the representatives with the authority of the leading schedule manufacturers and, under the proper legal advice, determine the proper course of procedure to accomplish the result desired.

I can recall the time when inclosed fuses were made not only in as many sizes as regards carrying capacity but in almost as many actual sizes and types. In those days before filling an order for inclosed fuses it was almost necessary in the majority of cases to obtain an actual sample of the fuse desired. With the adoption of the National Code standards of fuses, both as to type and dimensional size, the duplication and confusion was greatly reduced, although there is still opportunity for pruning as regards definite carrying capacities for which there is little or no necessary demand. The same condition existed in miniature lamps until the lamp manufacturers greatly reduced the large number of types, based on candlepower, size of bulb and base.

While the so-called schedule lines are the most conspicuous commodity lines in which duplication and obsolescence exist, and therefore the logical ones to start to cut, there are a number of other lines on which the same kind of constructive work can be done. I have in mind outlet boxes and covers, which could be materially reduced as regards the items cataloged, with no ill effects and many advantages to the industry; likewise pole-line hardware, under which come machine bolts, carriage bolts and lag screws, listed in almost innumerable lengths and diameters, with no indication by the manufacturer as to which are standard types and which are more or less special.

#### How the Jobber Can Help

Although the jobber can only use his influence on the manufacturers who are his main source of supply to work toward the end desired in the elimination of unnecessary items, he can do much in the management of his own business by adopting a policy of not stocking duplicate lines of manufacture. Instead of duplicating the slow-moving or even the fast-moving items of competing manufacturers, he should catalog and stock only the product of one manufacturer that will fulfill the individual requirements of his customers. This should be followed up by the salesmen selling this particular product instead of taking orders for any particular brand which the customer seems to favor.

We have endeavored to follow this policy for a number of years and as a result have been able to maintain a minimum stock and at the same time give improved service for products of this manufacturer on which we specialize. If more jobbers will adopt such a policy, the result will sooner or later be the development of the so-called "super-jobber" and a decreased cost of distribution. This is what all of us who are giving the matter any thought are aiming for.

#### Some Progress Made

In reviewing our figures for the past ten or twelve years it is gratifying to observe that the effort made in reducing the cost of distribution has not been in vain. Although our items of overhead have increased and our percentage of gross profit has decreased over this period, the average value of the order has increased, with the result that we have at least maintained our own as regards net

margin of profit. In other words, notwithstanding the increased actual cost of distribution, the percentage has decreased rather than increased, so that the jobber has been able to operate on a lower percentage of overhead. Of course, this does not apply during the periods of depression when with decreased volume the percentage of overhead has exceeded the percentage of gross profit.

The size of the jobbing line is a large factor in the situation, however, and presents an immediate practical opportunity to do something that actually affords relief. If one manufacturer can reduce his line, another can. If one jobber can reduce his line, so can his competitor. It all depends on whether or not they are willing to look economic laws in the face and do things that may be temporarily inconvenient, in order to help solve a problem for the entire industry.

## An Experience in Export Selling

**Success in Disposing of a Specialty Despite Restricted Market Makes Evident the Opportunity for American Electrical Appliances**

BY E. A. WIGHT

Export Manager Crescent Washing Machine Company, New Rochelle, N. Y.

WE ARE frank to admit that we are new in the export business. We have been selling our washing machines abroad for only about three years. But we are deeply interested in this field, and if we can continue for the remainder of the year the pace we have established, our export business will be from 10 to 15 per cent of our total yearly sales. Our largest markets are Great Britain, the Scandinavian countries, Australia, France, Spain, Switzerland, Italy and Belgium, in the order named.

### AGENTS WILLING TO INVEST

We are selling our own product only, although we are continually on the outlook for hotel and restaurant specialities that we can also handle through our agents. Because of the real effort that must be used to introduce our machines in any foreign market it has been our policy to favor exclusive representation. This we do not grant at once, but we put a company on probation for six or eight months. No concern abroad is going to attempt to handle machines like commercial dishwashers without a real hope for an exclusive agency.

Without exception, our agents have purchased the first machine outright. They have installed it on trial in some important restaurant or hotel in the city in which they live. If the machine should prove satisfactory, the restaurant was to pay for it; otherwise the agent would take it back. Thus you can see he was taking a chance in tying up money on the supposition that we, by our representatives and in our literature, were telling the truth about Crescent dishwashers. We are glad to say that without exception the foreign houses that have taken this chance have been successful in selling not only this first machine but many others.

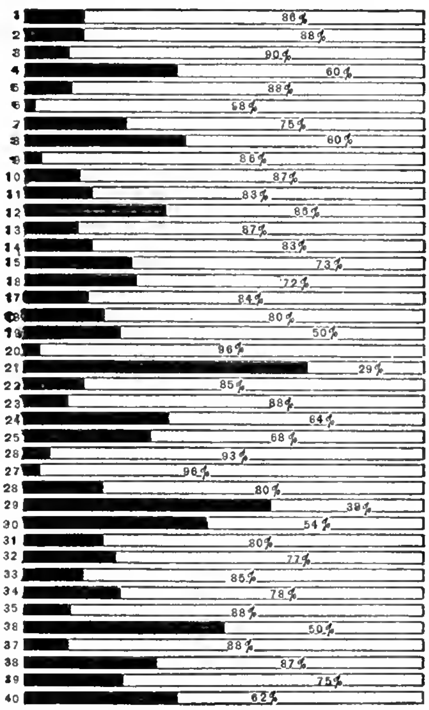
In England we have a condition of "no pressure" to overcome. While every restaurant and hotel that can use a machine has plenty of hot water, nevertheless the pressure is not sufficient to operate the "rinse" —really the most important part of any dishwasher. Therefore, we have had to develop a booster pump for this market. In France the people not only do not have pressure, but there are no hot-water-main supplies there. Even in the biggest restaurants the dishes are washed in sinks, under which gas burners are installed to keep the water hot. There is absolutely no hot-water-main supply, and our agent in that country, in order to sell a dishwasher, has usually to sell to begin with a hot-water system, costing three times as much as the dishwasher. Here again the machine and the entire hot-water system must be put in on trial. This means an outlay of close to $1,000 or more in the case of the larger dishwashers.

In Scandinavian countries the extremely hard water—particularly in Denmark—makes it hard to sell the Crescent against German tank machines. In Australia we no sooner had a good volume of business started than the duty was raised from 35 to 45 per cent ad valorem, and two concerns immediately started copying our larger models bolt for bolt and nut for nut. Our machines had been patented in this country long before we thought of exporting. Therefore, they could not be patented abroad, at any rate in Australia. Such conditions as I have named are typical the world over, and, combined with the relative cheapness of native labor, they necessitate the most up-to-date selling methods on the part of our agents.

### BROADENING THE LINE

We feel that we have been extremely fortunate in our selection of distributors. Every one of them is financially sound and pays for machines either by cash in advance or through a letter of credit in New York. Our agent in France, for instance, whenever a customer of his pays him in dollars, immediately forwards the check to us, and as a rule he keeps a substantial credit

## Elimination Progress in Industries



| Article | Reduction |
|---|---|
| 1. Baskets | 78—11 |
| 2. Bed springs | 206—28 |
| 3. Bottles, glass | 210—20 |
| 4. Bread | 15—6 |

| 31. Rubber goods | 145—29 |
| 32. Shafting | 60—14 |
| 33. Shotgun shells | ...... |
| 34. Steel lockers | 37—9 |
| 35. Stove parts | 2,982—364 |
| 36. Taps and dies | ...... |
| 37. Tires | 287—32 |
| 38. Toilet goods | 425—140 |
| 39. Water bottles | 20—5 |
| 40. Wheelbarrows | 42—16 |

balance here. The fact that we allow an extra 5 per cent discount for payment in New York is, of course, the reason why payment is made in this manner. Five per cent amounts to from $12 to $40 on each machine, so you can see it is well worth the expense of establishing a letter of credit in New York.

Every trade has its own difficulties to overcome, and I have enumerated a few of ours. I believe that we have overcome them, and I am sure that the next two years are going to see a steady increase of orders. Within the next two or three months we are going to start to introduce certain other specialties that we have permission from manufacturers in this country to handle. We did not immediately write to our agents the minute we secured representation for a certain article, but we have held off until our representatives were fully acquainted with and familiar with our own product before asking them to turn their attention to something else. We have wanted them to think and talk nothing but dishwashers for two or three years, without diverting their minds to some other new piece of equipment that they might sell. Now that our machines are fairly well established in various markets, sales resistance will be greatly reduced, and local advertising that we are doing will help to ease the hitherto heavy burden on the distributor.

### Specialty Handicapped

I do not believe that we have accomplished anything that has not been accomplished by every American manufacturer who has attempted to build up an export business. I have tried to point out, however, the real difference between our product and domestic electrical appliances and the method that must be used in marketing them both here and abroad. Perhaps one incident will better illustrate this point than further discussion. I have just been reading a trade information bulletin published by the Bureau of Foreign and Domestic Commerce on British India. In this bulletin I note the increased sales of electrical instruments, apparatus, etc., and I find that American sales are increasing in volume and dollar value, which would seem to indicate increasing sales possibilities for all electrical appliances. Yet in all British India there are not twenty "prospects"—even possible purchasers — of Crescent electric dishwashers.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

## Eastern Business Shows Little Change Over Last Week

BUSINESS in the Eastern territory shows little change over last week's volume. Prices are firm in current quotations of most commodities, and little scarcity of supplies is reported, barring a temporary uneven stock of rigid conduit. The larger sizes are most difficult to obtain in quantity at present. Jobbers' sales are well distributed among different classes of buyers. Interior wiring is absorbing great quantities of material and appliances are moving freely, sales of socket devices being particularly good.

Transportation conditions are improving rapidly as regards motor-truck service, and the railroad and steamship lines are doing their part to improve shipments. The expansion of central-station generating plants continues the chief feature of interest in utility construction, although a relaxation of regulations in regard to line extensions of moderate cost is apparent in this territory.

A comfortable money market prevails, and recent notes of caution appear to have made some headway in checking inflation tendencies. Some Fall River cotton mills have dropped to a four-day week in production as an offset to recent forced wage increases. Collections are improving.

Conditions in the shoe, metal-working, paper-making and wire factories reflect intense activity. The public is getting restive over the demands of labor in the building trades, and unquestionably much home building is being postponed until more favorable conditions arise.

## Evidences of "Easier Buying" in Industries Are Seen

IN CONNECTION with efforts of the electrical industry to avoid inflation of businesses supplying materials for new construction, developments in the building industry indicate that over-ordering of cement, which recently was made the subject of complaint by producers, is being taken up directly between the producers and with good prospects that orders will be pared to actual necessities, according to information received in official circles in Washington. It appears probable therefore that there will be no conference held with federal officials on this subject, as had been suggested at one time there would be.

Evidences of a "buyers' strike" in the construction industry, as reported in newspaper dispatches from various cities where temporary withdrawal of projects has been announced on account of high costs, are being watched closely by Washington officials. While a reasonable let-up in new construction projects would be welcomed as tending to relieve pressure upon material and supply houses and upon the labor supply, there is some fear that the psychological effect may extend to other lines of industry. Conditions in the building industry have been recognized as abnormal, and in considering possible inflation of business this industry has been set aside in a class by itself by government economists.

A general easing of business conditions since the middle of April has been noted in Washington, and it is considered by prominent government officials that the caution now being displayed has averted the possibility of a period of inflation.

## Fifty-four Opportunities for Elimination in Electrical Industry

MORE than one thousand outstanding opportunities for the elimination of economic waste through the simplification of varieties and sizes of products are presented in the first analysis of findings in the survey of simplification opportunities which has been carried on during recent months by the American Engineering Standards Committee at the request of Secretary Hoover of the Department of Commerce.

This is in the form of a summary of answers to a questionnaire sent out by the American Society of Mechanical Engineers, one of the member bodies of the A. E. S. C., to selected lists of its membership, which includes all members of its professional division. It shows 54 opportunities among electrical appliances and supplies; 123 suggestions of important standardization opportunities in the automotive and aircraft industries; 115 opportunities in building-material industries; 291 opportunities in tools and other machine-shop equipment; 64 opportunities in paper, catalogs, books and printing; 200 opportunities in boilers, valves, pumps, pipe supplies and kindred products; 37 opportunities in the railroad field, and 191 opportunities in miscellaneous industries.

Among the electrical materials simplification of which was suggested in the answers to the A. S. M. E. questionnaire, are the following: Electrical attachment plugs, diaphragms on radio head sets, electrical fixtures and boxes, lighting fixtures, electrical wiring fittings, panelboards and switches, electric fuses, electrical motors, motor bases and frames, electrical sockets, electrical vacuum cleaners, transformer oil, washing machines and insulated electrical wires.

Other developments in this activity by the committee are expected in the near future.

## Reduced Freight Rates Forgotten in Prosperity

THOSE Senators and Representatives who have been planning to make a drive at the next session of Congress for reduced freight rates are perturbed by the prospect that such agitation will not arouse any popular enthusiasm. When prices are good the average shipper is more interested in service than he is in the rate. On most electrical commodities the freight rate really represents a small percentage of the selling price.

When prices are hovering around the cost of production the freight charge looks big. For that reason the agitation of railroad legislation in 1921 and early in 1922 struck a popular chord. It appealed particularly to the demagogues of Congress. It is believed, however, that in prosperous times there will be no general support for any legislation which would instruct the Interstate Commerce Commission to regard an amount less than 6 per cent as a fair return or to take into account other factors which would have the effect of lowering rates.

Transportation specialists in Washington agree that more efficient service is being rendered by the railroads at this time than ever before has been the case. The proportion of unfilled car orders to the total loadings is very small. This has been made possible through closer co-operation and more friendly relationships with the shippers, through the reduction to the minimum of bad-order equipment, and through the placing in service of increasing numbers of new cars.

## Chicago Business Continues at Normal Stride

CHICAGO business continues normal. Jobbers report steady demand for electrical merchandise, although no exceptional activity is noticeable. Price advances were announced this week on single-phase fractional-horsepower motors and high-tension equipment of a certain class, and the former policy with reference to jobbers purchasing wiring devices was revised.

Single-phase, 1,725-r.p.m. motors ranging from ¼ hp. to ½ hp. advanced 10 per cent. Motors rated at ¼- ⅓- ½-hp., 1,140 r.p.m., advanced 7½ per cent. High-tension equipment of one class advanced approximately 5 per cent.

One manufacturer of wiring devices adopted the policy of selling only in standard-package quantities of twenty cartons. While this may appear as a hardship to the jobber, he will really benefit by this system ultimately. It is expected that other manufacturers will follow suit.

The demand for storage batteries has apparently decreased during the first part of May. This is attributed mainly to the fact that many consumers have had taxes to meet at this time and have held off their individual purchases accordingly, while throughout the country districts the farmer has been busy in his fields. The summer season coming on also brings a slowing up of radio-battery purchases. The situation on flatirons remains the same, while there is the normal demand for fans for this season of the year.

## Street Lighting Business Healthy in Various Parts of Country

SLOW but substantial growth of business with a steady interest in ornamental illumination characterizes present street-lighting equipment sales in various parts of the country. Although the close of the war opened the door for larger expenditures for street illumination, municipalities in many quarters have moved rather slowly in assigning marked increases in budgets for new development work in this field, and a good deal of skillful sales engineering has been necessary to spread the idea of improved service.

One manufacturing company found it helpful in showing representatives of municipal governments the latest progress in highway illumination to construct a working model built accurately to scale and equipped for varied demonstrations of unit spacing, variations in road surface, effect of miniature automobile headlight rays, etc., all arranged in a large darkened room and flexibly wired to facilitate quick and complete changes in apparatus.

Visits to the factory have been productive and a great deal of time has been saved in studying various layouts. So far as reported, there appears to be no difficulty of moment in making deliveries of either arc or incandescent street-lighting equipment. About this time of year municipal appropriations tend to keep manufacturing plants busier, and the general improvement of trade throughout the country is reflected in many additional orders, scattered to be sure, but effective in the rising volume of national sales.

## March Electrical Exports Show $1,344,544 Increase

TOTAL exports of electrical machinery, apparatus and appurtenances for March were $6,344,842, a gain of $1,344,544 over March, 1922, when the total amounted to $5,000,298. In February, 1923, total electrical exports amounted to $4,839,738. The following figures are supplied by the Bureau of Foreign and Domestic Commerce:

ELECTRICAL EXPORTS FOR MARCH, 1923, COMPARED WITH CORRESPONDING PERIOD A YEAR AGO

| Articles | Value — March 1922 | 1923 |
|---|---|---|
| Turbines | $23,759 | $7,570 |
| Generators: | | |
| Direct-current— | | |
| Under 500 kw. | 36,835 | 67,830 |
| 500 kw. and over | 52,607 | 92,049 |
| Alternating-current— | | |
| Under 2,000 kva | 23,081 | 10,960 |
| 2,000-kva. and over | 143,866 | 131,022 |
| Accessories and parts for generators | 22,148 | 38,695 |
| Self-contained lighting outfits | 25,165 | 57,514 |
| Batteries: | | |
| Primary | 111,620 | 123,388 |
| Storage | 117,147 | 176,669 |
| Transforming and converting apparatus: | | |
| Transformers— | | |
| Power | 298,379 | 362,707 |
| Other | 19,607 | 59,167 |
| Rectifiers, condensers, double-current and motor generators, dynamotors, synchronous and other converters | 47,486 | 250,844 |
| Transmission and distribution apparatus: | | |
| Switchboard panels, except telephone | 65,125 | 138,588 |
| Switches and circuit breakers above 10 amp. | 150,212 | 166,180 |
| Fuse and fuse blocks | 11,187 | 21,551 |
| Meters and measuring instruments: | | |
| Watt-hour and other measuring instruments | 51,954 | 49,022 |
| Volt, watt and ampere meters and other recording indicating and testing apparatus | 61,316 | 103,206 |
| Lightning arresters, choke coils, reactors and other protective devices | 20,628 | 42,254 |
| Motors, starters and controllers: | | |
| Motors under 1 hp. | 71,171 | 128,276 |
| Stationary motors 1 to 200 hp. | 181,394 | 217,155 |
| Stationary motors over 200 hp. | 65,880 | 65,295 |
| Railway motors | 5,000 | ..... |
| Electric locomotives— | | |
| Railway | | 474,098 |
| Mining and industrial | 14,553 | 18,780 |
| Other motors | 19,738 | 13,183 |
| Rheostats, controllers and other starting and controlling equipment | 52,216 | 137,373 |
| Accessories and parts for motors | 112,242 | 112,470 |

| Metal conduit, outlet and switch boxes | 16,832 | 51,784 |
| Sockets, receptacles and lighting switches | 16,079 | 90,673 |
| Other wiring supplies and fixtures | 77,357 | 204,647 |
| Other electrical apparatus not elsewhere specified | 11,080,188 | 644,170 |
| Globes and shades for lighting fixtures | 29,787 | 39,561 |
| Electrical glassware, except for lighting | 16,043 | 24,301 |
| Electrical porcelain | 176,323 | 169,662 |
| Electrical carbons, carbon brushes and electrodes | 54,451 | 184,956 |
| Insulated wire and cable (iron or steel) | 27,692 | 83,103 |
| Other manufactures of aluminum | 86,096 | 66,062 |
| Copper: | | |
| Bare wire | 208,661 | 111,033 |
| Insulated wire and cable | 129,002 | 408,374 |
| Total electrical exports | $5,000,298 | $6,344,842 |

*Not separately stated prior to Jan. 1, 1923.

## New England Appliance Sales Show Marked Increases

SALES of socket appliances in New England reflect a remarkable increase in buying power on the part of the public compared with last year. The demand for washers and cleaners has reached a point where substantially full plant capacity must be utilized to meet the needs of the national market. One large manufacturing plant in this section is now working at night on production. Prices are holding firm on the better-grade products.

One representative distributor of socket devices said recently that his sales are double those of last year to date. Transportation embargoes are being gradually done away with, but rail shipments are still slow and unsatisfactory in this section, especially on freight handled through New England gateways. Retail buying of appliances is greatly stimulated by the growing use of national advertising, accompanied by intensive local sales campaigns.

## English Electrical Exports £165,129 in March

THE following are official values of electrical machinery, apparatus and material exported from England (*a*) during March, 1923, and (*b*) the aggregate figures from Jan. 1 to March 31, with increase or decrease compared with corresponding periods in the year 1922.

The total exports of electrical machinery, material and apparatus, other than insulated wire, were £949,457 for March, which was a decrease of £165,129 from those exports during the month of February, 1922:

Electrical machinery (*a*) £296,524 (decrease £188,591), (*b*) £1,015,716 (decrease £420,678); including railway and tramway motors, (*a*) £21,663 (decrease £891), (*b*) £66,654 (increase £13,044); other generators and motors, (*a*) £140,922 (decrease £136,529), (*b*) £526,949 (decrease £272,241); and other electrical machinery, (*a*) £133,939 (decrease £51,171), (*b*) £422,113 (decrease £161,481); telegraph and telephone cables, submarine, (*a*) £47,281 (increase £29,508), (*b*) £149,676 (increase £69,425); other than submarine (*a*) £98,476 (increase £68,637), (*b*) £220,385 (increase £74,649); telegraph and telephone apparatus, (*a*) £116,557 (decrease £63,709), (*b*) £462,213 (decrease £78,856); other electrical wires and cables, rubber insulated (*a*) £82,964 (increase £34,437), (*b*) £296,526 (increase £150,953); with other insulations, (*a*) £92,610 (decrease £5,900), (*b*) £269,398 (decrease £68,069); carbons, (*a*) £7,183 (increase £3,681); (*b*) £17,342 (increase £4,734); glow lamps, (*a*) £20,795 (decrease £17,554), (*b*) £76,033 (decrease £20,909); arc lamps and searchlights, (*a*) £943 (decrease £810), (*b*) £1,689 (decrease £1,156); parts of arc lamps and searchlights (other than carbons) (*a*) £162 (decrease £449), (*b*) £246 (decrease £1,146); batteries, (*a*) £48,934 (increase £1,414), (*b*) £143,457 (increase £37,544); electrical instruments (commercial and scientific) and electricity meters, (*a*) £21,324 (decrease £12,423), (*b*) £78,317 (decrease £27,624); switchboards, (*a*) £3,934 (decrease £11,567), (*b*) £26,980 (decrease £98,885); other electrical goods and apparatus, (*a*) £111,770 (decrease £1,803), (*b*) £324,051 (decrease £12,798). Total of electrical machinery, material and apparatus other than insulated wire, (*a*) £949,457 (decrease £165,129), (*b*) £3,082,029 (decrease £394,808).

## The Metal Market

Conditions are little different in the non-ferrous metal market from those that have existed during recent weeks. The international situation still dominates the market, and so long as London prices exhibit almost continuous declines from day to day buyers on this side are likely to hold off. The time must soon come, however, when supplies will be needed for nearby consumption, and there is then likely to be a scramble for early deliveries. Germany is not taking anywhere near her normal requirements of metal, and as she is the most important consumer in Europe, her withdrawal from the market has had a bad effect.

The Ruhr difficulty seems to be no less unsettled than last week, and there seems to be little hope of an immediate improvement. Without a stronger feeling in the London metal market, prices cannot advance here until buying in substantial volume appears. The bright spot is that consumption has not fallen away to any great extent and buyers must soon come into the market for at least small tonnages to meet current requirements.

NEW YORK METAL MARKET PRICES

| | May 9, 1923 Cents per Pound | May 16, 1923 Cents per Pound |
|---|---|---|
| Copper, electrolytic | 16.62½ | 15.75 |
| Lead, Am. S. & R. price | 8.00 | 7.75 |
| Antimony | 8.00 to 8.25 | 8.00 |
| Nickel, ingot | 28.00–30.00 | 28.00 to 30.00 |
| Zinc, spot | 7.37½ | 7.15 |
| Tin, Straits | 45.00 | 45.00 |
| Aluminum, 98 to 99 per cent | 26 00 | 26.00 |

The last government report shows March exports of copper to have been 61,531,000 lb., exclusive of shipments to Canada. This figure includes finished as well as unwrought copper and makes the total for the first quarter approximately 185,000,000 lb. With April estimated at 80,000,000 lb., total for first four months is 265,000,000 lb.

# Activities of the Trade

Devoted to News of the Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Electric Storage Battery Reports Largest Year in Its History

The Electric Storage Battery Company, Philadelphia, reports the largest year in its history, according to Herbert Lloyd, president. Mr. Lloyd said the demand for automobile, radio and telephone accessories continues unabated and that a shortage of skilled labor would be the only factor that might serve to restrict production.

"Orders are coming in in considerable volume," he continued. "The Crescentville plant is operating at two-thirds capacity and the remainder will be equipped and ready in the near future. That part of the new plant that has been in operation for six months has demonstrated its efficiency. We are now employing four thousand men and women, more than ever before were on the payroll."

## Link-Belt Moves Pittsburgh Office

Notice has recently been received of the removal of the Link-Belt Company's Pittsburgh branch office from its old quarters at 1501 Park Building to its new and more commodious offices at 335 Fifth Avenue. T. F. Webster, manager of the Pittsburgh office, says that larger space and the more convenient location were imperative because of the large volume of business transacted during the past year, which promises to remain in full swing at least for the coming fiscal year.

## Pelton Water Wheel Order

The Western States Gas & Electric Company has awarded a contract for building a 72-in. butterfly valve to the Pelton Water Wheel Company. This valve will operate under a head of 65 ft. and will be installed at the head of the penstock at the power company's new Eldorado plant near Placerville, Cal. It will be designed for both direct and remote control and for electric motor and hand operation.

## Westinghouse, Except Radio, Is Filled to Limit with Orders

The Westinghouse Electric & Manufacturing Company is working at full capacity in every department excepting the radio division. The production of small motors is nearly 300 per cent greater than a year ago.

A. B. Reynders, works manager at Springfield, predicts that radio is due for a revival. He says: "Production in our radio department has fallen off since January, chiefly because we have suspended operations to a certain extent while disposing of enormous accu-

mulated stock of apparatus completed last year.

"The demand has been so large that our surplus stocks have nearly been absorbed, and we shall resume production in this department at the normal rate soon. The outlook for industry in the electrical field is very favorable. If the radio demand continues, we expect to be more busy during the next four than during the past four months."

### Square D Appointments

The Square D Company, safety-switch manufacturer, Detroit, announces the following recent additions to its sales force:

H. R. Thornburgh, formerly of the Western Electric Company, and W. F. Clarke of the M. W. Duncan Company, manufacturer of "Nokorode" paste, Providence, R. I., have been added to the New York branch organization. R. W. Coblentz has taken over the Northwest Pacific Coast territory and has established himself at Portland, Ore., under the direction of E. S. Conrad of the San Francisco branch. E. J. Burke will help handle the Philadelphia territory.

H. N. Foster, recently with the W. J. Fisher Company, manufacturers' agent, Detroit, has joined the Detroit sales force.

### Rome Wire Offering New Issue of $3,000,000 Gold Notes

A new issue of $3,000,000 three-year 6 per cent sinking-fund gold notes, due May 1, 1926, is being offered by the Rome Wire Company, manufacturer of copper rods, wire and cables.

The Rome Wire Company, incorporated in New York in 1905, has its main plant at Rome, N. Y. Plants are situated on 45 acres of land and have 669,000 sq.ft. of floor space. Output in 1922 was more than 76,000,000 lb. of copper rods, copper wire and copper-wire products. Sales in 1922 were in excess of $10,000,000.

Total net assets, upon completion of the present financing, amount to $8,404,562, or 280 per cent of this $3,000,000 issue, constituting the company's total funded debt. These net assets include all securities of the Buffalo subsidiary, except $500,000 notes which the company has guaranteed. Fixed assets are carried on the books at $2,667,221, considerably less than value based upon outside appraisal in 1920 and additions since that time. Net current assets alone are $5,674,488.

### E. C. Butler Now Associated with American Electric Equipment Firm

Edwin C. Butler has discontinued the electrical contracting business under the name of E. C. Butler Electric Corporation, 1402 Broadway, New York City. He is now associated with the engineering and sales division of the American Electric Equipment Company, subsidiaries of which are the Localized Lighting Corporation and the Home Lighting Equipment Corporation. This company makes a line of lighting fixtures for the factory, office and home, the operating principle of which is covered by the well-known patents of the Anderson adjustable arm, namely friction disks and interior disk wiring. The office is in the Longacre Building, 151 West Forty-second Street.

### Copper Export Directors Chosen When Guggenheims Quit

Directors of the Copper Export Association were re-elected last week. Murry and Simon Guggenheim resigned as directors and Stephen Birch, president of the Kennecott Copper Corporation, and John K. MacGowan, vice-president of the Braden Copper Company, took their places to fill the remainder of their unexpired terms.

The retirement of the Guggenheims is said to have no significance other than that they felt it would be better to have two of their executives upon the board dealing with technical matters.

### Riley Stoker Sales Abroad and at Home

The Sanford Riley Stoker Company, Worcester, Mass., has received a contract for four 1,600-hp. automatic stokers from the Nippon Power Company for installation in a plant in Tokyo, Japan. About ten cars will be required to transport the parts across the United States for Oriental shipment.

The company has recently shipped five carloads of stokers to Sydney, Australia, for the generating station of the municipal council. An order for four large stokers has been received from the Public Service Electric Company, Newark, N. J., and also four for the municipal generating plant at Lansing, Mich.

**The Westland Engineering Supply Company**, 760 Monadnock Block, Chicago, recently capitalized at $5,000, will manufacture and deal in power plant parts and appliances. Benjamin E. Seaman, Harry M. Everson and Lillian Everson are incorporators.

**The Pittsburgh Transformer Company**, Columbus and Preble Avenues, Pittsburgh, manufacturer of electrical equipment, has acquired property at Juniata and Metropolitan Streets for extensions. R. V. Bingay is president.

**The United States Electrical Tool Company**, Cincinnati, announces that it has established a branch at 430 North High Street, Columbus, Ohio, E. W. Beeler in charge, and another at 412 First National-Soo Line Building, Minneapolis, Thomas H. Caley in charge.

**The Instant Electric Water Heater Company**, Bridgeport, Conn., recently organized with capital stock of $250,000, will succeed to the business of the Bridgeport Manufacturing Company. A plant has been leased at Knowlton Street and East Washington Avenue. H. E. Dineson is president.

**The Appliance Manufacturing Company**, 10 Hoadley Place, Hartford, Conn., is a recent incorporation to make and deal in electrical appliances, etc. The firm will have a capital stock of $50,000, and the officers chosen the past week include F. E. Wolcott of Hartford, president and treasurer; J. S. Wolcott, vice-president, and G. H. Anthony, secretary. The concern has established a plant at the address mentioned above.

**Harvey Hubbell, Inc.**, of Bridgeport, Conn., manufacturer of electrical switches, sockets, etc., has increased its capital stock from $300,000 to $2,000,000, consisting of 15,000 preferred and 5,000 common shares of stock, par value $100.

**The Bryant Electric Co.**, Bridgeport, Conn., large manufacturers of electric switches, etc., recently increased its capital stock from $2,000,000 to $3,000,000, the increase consisting of 40,000 shares of common stock with a par value of $25. The firm completed several large building additions to its plant in the last two years, and the plant is very busy at the present time.

**The Robertson-Cataract Company**, Buffalo, N. Y., plans to open a distributing branch in Watertown, N. Y.

**Stovel & Brinkerhoff**, electrical engineers, 136 Liberty Street New York City, announce the addition of H. M. Van Gelder as a partner and a change of name to Stovel, Brinkerhoff & Van Gelder. Mr. Van Gelder, member A. I. E. E., has had an active experience of over twenty years in electrical engineering and construction.

**C. Brandes, Inc.**, manufacturer of radio head sets, 237 Lafayette Street, New York City, has recently added another 5,000 sq.ft. of floor space and much new equipment to its assembly plant in order to increase production.

**The Fay Mendenhall Electric Company**, 44 West South Street, Indianapolis, Ind., is planning for an addition to its plant and the installation of equipment.

**E. D. & A. F. Cronk, Inc.**, Hotel Street, Utica, N. Y., has plans for the construction of a two-story addition to its electric motor and equipment manufacturing plant. T. H. Williams, Devereaux Block, Utica, is architect.

**The Crescent Truck Company**, Lebanon, Pa., manufacturer of electric trucks and tractors, is building a one-story addition, 40 ft. x 100 ft., to its factory in order to enlarge production facilities.

**The Ace Electric Cord Adjuster Company**, Twenty-fifth Street and Park Avenue, New York City, is the name of a recent incorporation for $20,000 to manufacture electrical equipment. The incorporators are G. F. Brown, A. Helfat and W. H. Oakes.

**Ross, Inc.**, 5414 Rainier Avenue, Seattle, Wash., recently organized to manufacture electric ovens and heating appliances, has obtained a factory and purchased equipment. A. R. Ross heads the company.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

An agency is desired in Turin, Italy (No. 6,362), for electrical novelties for household use.

An agency is desired in Vienna, Austria (No. 6,382), for air compressors of small dimensions which can be easily attached to the automobile or air compressors which are operated by electric motors from a battery in the car.

An agency is desired in Marseilles, France (No. 6,407), for light, strong, easily conducted electric or gasoline tractors, capable of being used in shipyards, railway stations, factories and on farms.

An agency is desired in Cairo, Egypt (No. 6,413), for railway engines, telephone equipment, Diesel and semi-Diesel engines, ice-making machines, etc.

An agency is desired in London, England (No. 6,430), for intercommunicating telephone equipment.

AUTOMATIC TELEPHONES PROPOSED FOR RIGA.—A new automatic telephone system to replace the present system in Riga, according to *Commerce Reports*, has been proposed by the General Director of the Latvian Post and Telegraph Bureau of the Ministry of Communication. The plans call for a machine-switching telephone exchange capable of caring for 10,000 lines, with a maximum of 20,000 lines. It is proposed to install the new system in the building erected for that purpose in 1914. The installation will be extended over a period of about four years. The cost is estimated at about $600,000.

DEMAND FOR ELECTRICAL GOODS INCREASING IN INDIA.—Owing to extensions of electric power facilities and the popularity of electric drive in Indian mills, *Commerce Reports* states, the demand for electrical goods is increasing in India.

PROPOSED ELECTRIC PLANT FOR PENANG.—Tenders are being called, *Commerce Reports* states, through the crown agents for an electric light plant for the city of Penang and the new Prai docks, Straits Settlements. The crown agents, it is reported, are also calling for bids for new telephone equipment for Penang.

DEMAND FOR POWER-PLANT EQUIPMENT IN NORWAY.—Power-plant equipment and supplies, according to *Commerce Reports*, are in good demand in the district around Bergen, Norway. In the districts of More, Sogn og Fjordene and Hordaland there are 664 power stations with a total capacity of 279,885 kw. A list of Bergen commission agents interested in electrical equipment may be obtained from the Electrical Equipment Division, Bureau of Foreign and Domestic Commerce, Department of Commerce, Washington, by referring to file No. 91,960.

# New Apparatus and Publications

ELECTRIC LIGHTING FIXTURES—The Louisville Composition Products Company, 840 East Jefferson Street, Louisville, Ky., has issued catalog "C," which describes and illustrates its various types of lighting fixtures.

POWER HACKSAW.—A power hacksaw designed for precision work when sawing materials has been placed on the market by E. C. Atkins & Company, Indianapolis, known as the "Kwik-Kut."

HEATING PAD.—The Edison Electric Appliance Company, Inc., 5660 West Taylor Street, Chicago, has brought out a new flexible cloth heating pad.

SWITCH PANEL.—A master switch panel has been placed on the market by the Palmer Electric & Manufacturing Company, 175 Fifth Street, Cambridge, Mass.

MINING MACHINE.—An improved model of the "Arcwell" mining machine, used particularly for low seams of coal, has been brought out by the Jeffrey Manufacturing Company, Columbus, Ohio.

BATTERY TERMINAL PULLER.—A battery terminal puller which can be used without pliers, screwdrivers or other tools has been brought out by the Bird Manufacturing Company, Marshalltown, Iowa.

ELECTRIC HOISTS.—The Link-Belt Company, 910 South Michigan Avenue, Chicago, has issued a book on "Electric Hoists and Overhead Cranes" which contains illustrations showing some of the most recent "Link-Belt" electric hoist applications, with line and wash drawings. The publication is known as "Book No. 480."

BLUEPRINTING MACHINE.—Wickes Brothers, Saginaw, Mich., have placed on the market a blueprinting machine for printing continuous rolls or separately cut sheets.

ELECTRIC RANGE.—An electric range with two electric units in an insulated oven has been brought out by the Magee Furnace Company, 38 Union Street, Boston.

ELECTRIC WASHING MACHINE.—The Station-Airy Company, Pitt Building, Cleveland, has brought out an electric washing machine, known as "Station-Airy."

FLOOD LIGHT.—The Pyle National Company, 1334 North Kostner Avenue, Chicago, has developed a new flood light, known as the "Pyle-O-Light."

# New Incorporations

THE MONTAUP ELECTRIC COMPANY, Fall River, Mass., has been incorporated with a capital stock of $7,500,000 to generate, transmit and sell electricity to the Blackstone Valley Gas & Electric Company, the Fall River Electric Company and the Edison Electric Illuminating Company of Brockton. The officers are: Simeon B. Chase, president; Henry B. Sawyer, treasurer; Roy F. Whitney, A. Stuart Pratt and Victor D. Vickery, directors.

THE KELSO-WURDACK COMPANY, 2169 Railway Exchange Building, St. Louis, has been organized to manage, own and operate utility plants and other companies. The company will take over the control of the companies previously operated by the Light & Development Company of St. Louis. It is also prepared to render engineering, managerial, financial and other services usually furnished to utility properties. The officers are: Hugo Wurdack, president; J. A. Porter, vice-president; I. R. Kelso, secretary; E. Strauss, treasurer, and E. S. Billings, chief engineer.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

DANBURY, N. H.—The Ford Motor Company, Highland Park, Mich., contemplates the installation of a power plant at its proposed local garnet powder works, to be used in connection with manufacture of glass, to cost about $150,000.

DORCHESTER, MASS.—The Boston Insulated Wire & Cable Company, 65 Bay Street, has filed plans for an addition, 40 x 40 ft., to its power house.

HOLYOKE, MASS.—Rights-of-way have been secured by the Turners Falls (Mass.) Power & Electric Company for a transmission line to Holyoke and also a site on the North Chicopee bank for a substation.

PLYMOUTH, MASS.—The Plymouth Electric Light Company has awarded contract to the Fred Ley Company, Boston, for the erection of 10 miles of high-tension transmission line, to cost about $35,000.

PAWTUCKET, R. I.—Extensive improvements are contemplated by the Blackstone Valley Gas & Electric Company to its systems in Woonsocket and Pawtucket, involving an expenditure of about $2,500,000. The plans for 1923 include the erection of additional tie lines to provide additional supply of energy to the Woonsocket division, the completion of the line between Woonsocket and Pawtucket, which will enable it to obtain power from either the Rhode Island Power Transmission Company or its own power station, the erection of an outdoor substation at Riverside and the complete rehabilitation of the distribution in Woonsocket. The work will be in charge of the Stone & Webster Engineering Corporation, Inc., Boston.

SOUTH NORWALK, CONN.—Contract has been awarded by the Crofut & Knapp Company for the construction of a power house, 50 ft. x 100 ft., in connection with its new hat factory. The cost of the entire plant is estimated at about $1,000,000.

## Middle Atlantic States

BUFFALO, N. Y.—The Buffalo General Electric Company will erect a one-story building, 103 x 180 ft., near its power plant on Niagara Street, for general operating service.

NEW YORK, N. Y.—Bids will be received by S. B. Wight, agent, Room 338, 466 Lexington Avenue, New York City, until May 25 for incandescent lamp bulbs required by following companies for one year, to be covered by serial contract No. 16-1923: New York Central Railroad Company, Boston & Albany Railroad, Grand Central Terminal, Troy Union Railroad, New York & Harlem Railroad, New York State Railways, Rochester (N. Y.) Gas & Electric Corporation, Cleveland, Cincinnati, Chicago & St. Louis Railway, Indiana Harbor Belt Railroad Company, Union Passenger Depot Association, Cleveland; Schenectady (N. Y.) Railway Company, Rutland Railroad Company, Michigan Central Railroad Company, Pittsburgh & Lake Erie Railroad Company, Monongahela Railway, Trunk Line Association, Cincinnati Northern Railroad, Peoria & Eastern Railway Company, Chicago River & Indiana Railroad Company.

OGDENSBURG, N. Y.—The Ogdensburg Power & Light Company plans to erect a building for general operations at Caroline and Ford Streets, to cost about $150,000.

WATERTOWN, N. Y.—Bids will be received by Walter Ackerman, city manager, until May 25 for all work in connection with the construction of a hydro-electric plant in the city of Watertown. Paul B. Sutton is city engineer.

ELIZABETH, N. J.—Plans for the proposed plant to be erected on West Grand Avenue by the American Type Founders' Company, Communipaw Avenue, Jersey City, for the manufacture of printing presses, include a power station. The cost of the works is estimated at $500,000.

NEW LISBON, N. J.—Bids, it is understood, will soon be asked by the Department of Charities and Correction, Trenton, for the construction of a power house and ice-manufacturing plant at the Colony for Feeble-Minded, New Lisbon, to cost about $35,000. A. B. Mills, State Office Building, Trenton, is engineer.

CARLISLE, PA.—The West Pennsboro-Carlisle Electric Company, recently organized, plans to erect a transmission line and system for commercial service in this district. George M. Hays is interested in the company.

CONNEAUTVILLE, PA.—The Council has secured permission to acquire the local system of the United Electric Company, to be operated by the municipality. Extensions and improvements will be made.

EBENSBURG, PA.—Plans for the new hospital to be established at Ebensburg by the Commissioners of Cambria County and the Johnstown Society for the Prevention of Tuberculosis, both of Johnstown, to cost about $300,000, include a power plant. W. R. Myton, Johnstown, is architect.

LANCASTER, PA.—The United Gas & Electric Company, 61 Broadway, New York City, has acquired a number of electric companies in this section and will merge the systems, to be operated in conjunction with the Harrisburg (Pa.) Light & Power Company. The transmission lines will be extended and additional equipment installed.

LYKENS, PA.—The American Briquette Company plans to rebuild its power plant, recently damaged by fire, causing a loss of about $200,000.

SLATINGTON, PA.—The American Slate Company contemplates rebuilding its power plant, recently damaged by fire, causing a loss of about $100,000.

TUNKHANNOCK, PA.—The Sullivan County Electric Company has acquired the property of the Tunkhannock Electric Company and will merge the systems. Extensions and improvements will be made; a transmission line is planned.

WARREN, PA.—Electric power equipment will be installed by the Conewango Refining Company, in connection with the rebuilding of its oil refinery, recently damaged by fire, causing a loss of about $600,000.

HAVRE DE GRACE, MD.—The Tiger Tire Company, Toronto, Ontario, Canada, will build a power plant in connection with a proposed local plant, to cost about $200,000.

BRISTOL, VA.—The Bristol Gas & Electric Company plans extensions and improvements to its system, to cost about $50,000.

HERNDON, VA.—Bids will be received by the Fairfax & Loudoun Light and Power Company until May 22 for erecting 13½ miles of 22,000-volt, three-phase wood-pole line, the material for same to be furnished by the company.

WASHINGTON, D. C.—Bids will be received by the General Purchasing Officer, Panama Canal, until June 4, for electrical equipment for towing locomotives. (Circular 1529.)

WASHINGTON, D. C.—Bids will be received by the Chief of Engineers, United States Army, until June 15, for two Diesel engine-generating sets, with auxiliary apparatus, 150 kw. and 300 kw. capacity; also for miscellaneous spare parts for engines and generators.

WASHINGTON, D. C.—Bids will be received by the Chief Signal Officer, United States Army, until May 26, for switchboard supplies, including line jacks, relay assemblies, lamps, etc. (Circular PR-14773- 1CP); until May 28, for ten telephone battery charging rectifiers (Circular PR-14123-14CP); until May 25, for 120 dynamotors (Circular PR-14600- 6CP); until May 26, for thirty-six terminal boxes (Circular 14732- 1CP).

## North Central States

DETROIT, MICH. — The Detroit Steel Corporation will build a power house at its proposed plant in the Oakwood section to cost about $250,000.

DETROIT, MICH. — The Ford Motor Company has awarded a contract to Stone & Webster, Inc., 147 Milk Street, Boston, for the construction of a 10,000-hp. hydro-electric plant on the Menominee River, near Iron Mountain. Stone & Webster, Inc., is now starting work on a large combined hydro-electric and steam power plant at the High Dam at St. Paul. Plans are also being prepared for a large manufacturing plant for the Ford Motor Company adjacent to the High Dam by Stone & Webster, Inc.

IRON MOUNTAIN, MICH.—The Michigan Iron, Land & Lumber Company is having plans prepared for a hydro-electric power plant, to cost about $1,000,000. Mead & Seastone, Journal Building, Madison, Wis., are engineers.

ZILWAUKEE, MICH.—The Consumers' Power Company, Jackson, has authorized plans for a 54,000-hp. steam-driven generating plant to cost about $3,000,000. Plans previously prepared for a power plant of about one-half this size will be abandoned.

CLEVELAND, OHIO—Separate bids will be received at the office of the commissioner of purchase and supplies, City Hall, Cleveland, until May 25 for lead-covered cable, steam boilers and superheaters, and for weatherproof copper wire for the division of light and power.

COLUMBUS, OHIO.—The City Council is considering an ordinance providing for an issue of $235,000 in bonds for the purchase of new equipment for the municipal electric light plant, including a 7,500-kw. generating unit and condenser, etc. The installation of a new street-lighting system in the business district is also under consideration by the Council.

LIMA, OHIO.—Arrangements are being made by the Ohio Power Company to increase its service in Lima. A substation will be built in the southern part of the city (the factory district), and transmission lines will be erected to tie the Lima plants with power units in Toledo, Cleveland, Youngstown, Fort Wayne, St. Mary's and Delphos.

UPPER SANDUSKY, OHIO.—The City Council has passed an ordinance authorizing an issue of $80,000 in bonds for the erection of an electric distributing system in Upper Sandusky. Electricity will be purchased from the Ohio Power Company.

LOUISVILLE, KY.—Plans are being prepared by H. M. Byllesby & Company, 208 South La Salle Street, Chicago, for extensions to the steam-power plant of the Louisville Gas & Electric Company on the River Road, to cost about $150,000.

PADUCAH, KY.—The Paducah Electric Company will enlarge its power house and install additional equipment, including a 2,500-kw. turbo-generator, boilers, coal and ash-handling machinery and auxiliary equipment, to cost about $300,000.

FORT WAYNE, IND.—The Board of County Commissioners will build a power house in connection with the proposed court house building, to cost about $500,000.

LAFAYETTE, IND.—The construction of a new heating and power plant this summer for the Purdue University has been approved by the board of trustees. The cost is estimated at $300,000.

ATHENS, ILL.—The Public Service Commission has granted the Central Illinois Public Service Company permission to purchase the local electric plant. The transmission line from Athens to Petersburg will be rebuilt.

LUCK, WIS.—The Luck Light & Power Company has applied to the Railroad Commission for authority to issue $5,000 in capital stock for extensions and improvements to its plant.

MILWAUKEE, WIS.—Contract has been awarded by the Milwaukee Electric Railway & Light Company for the construction of a turbine and boiler house at Lakeside, to cost about $1,000,000.

WAUKESHA, WIS.—The Board of Public Works is receiving bids for extending the ornamental lighting system on Broadway, Madison, Grand, Main, Clinton and South Streets, to cost about $25,000. A. P. Kuranz is city engineer.

MINNEAPOLIS, MINN.—Plans are being prepared by the Minneapolis General Electric Company for the construction of a terminal station at First and Aldrich Avenues, to cost about $75,000.

CHEROKEE, IOWA. — The Cherokee Electric Company contemplates erecting an addition to its power station and installing new equipment. Contract, it is understood, has been placed for a 250-hp. engine.

DUNBAR, IOWA.—The Dunbar Light & Power Company, recently organized, plans to supply electricity in Dunbar and vicinity. John Ingebritson is president.

SHENANDOAH, IOWA.—Bids will soon be called for an ornamental lighting system in the business section. The Henningson Engineering Company, Twelfth and Harney Streets, Omaha, Neb., is consulting engineer.

WATERLOO, IOWA. — Electric power equipment will be installed in the five-story ice manufacturing and cold-storage plant, 90 ft. x 100 ft., to be built by the Rath Packing Company, Elm and Sycamore Streets, to cost about $150,000.

KANSAS CITY, MO.—The Kansas City Power & Light Company plans to build an addition to its building at Twenty-fifth Street and Pennsylvania Avenue for general operating and mechanical service.

LUDLOW, MO.—The citizens have authorized the installation of an electric lighting system. The service will be supplied by the Northwest Missouri Power & Light Company, Excelsior Springs.

MOBERLY, MO.—Electric power equipment will be installed in the local ice-manufacturing and cold storage plant to be erected by the Polar Wave Ice & Fuel Company, 3626 Olive Street, St. Louis, to cost about $250,000.

POTOSI, MO.—Steps have been taken by the Chamber of Commerce to establish an electric plant in Potosi.

ST. LOUIS, MO.—The Missouri Pacific Railroad Company plans to build a power house in connection with its proposed local grain elevator, to cost about $1,000,000.

ST. LOUIS, MO.—Electric power equipment will be installed in the ice-manufacturing and refrigerating plant to be erected by the St. Louis Dairy Company at Twentieth and Pine Streets, estimated to cost $100,000.

FARGO, N. D.—The Union Light, Heat & Power Company contemplates installing an additional generating unit, condenser type, to double the output of its plant. The cost is estimated at about $300,000.

BERESFORD, S. D.—Investigations are being made with a view of extending the service of the municipal electric light plant to Alsens and also to furnish electricity to residences along the line.

PIERRE, S. D.—Bids will soon be called for the installation of an electric distributing system. The Charles L. Pillsbury Company, 1200 Second Avenue, South, Minneapolis, is engineer.

ADAMS, NEB.—Improvements to the municipal electric light plant, to cost about $6,000, are under consideration.

AINSWORTH, NEB.—The electric plant of the Ainsworth Light & Power Company was recently damaged by fire, causing a loss of about $20,000.

SILVER CREEK, NEB.—Plans are under consideration to rebuild the distribution system of the municipal electric plant.

SEVERY, KAN.—The City Council is negotiating with the officials of the Eastern Kansas Electric Company to erect a high-tension transmission line to Severy to supply electricity to operate the local system. The company offers to erect the line to the municipal plant and erect a substation. The city is to pay $12,500 toward the construction of the line.

## Southern States

CONCORD, N. C.—The Concord Knitting Company will build an electric power plant in connection with a proposed cotton mill.

LEXINGTON, N. C.—C. M. Wall & Son plan to rebuild their power house and wood-working mill, recently destroyed by fire.

RIDGEWAY, S. C.—Bonds to the amount of $58,000 have been sold, part of the proceeds to be used for an electric lighting system.

COLUMBUS, GA. — Extensive improvements, to cost about $100,000, are under consideration by the Columbus Electric & Power Company. The work will include the erection of a substation on Second Avenue and the installation of three large transformers at the Goat Rock station. Connection has been made with the system of the Georgia Railway & Power Company, which has increased the voltage from 66,000 to 110,000.

ST. PETERSBURG, FLA.—The St. Petersburg Power & Lighting Company is reported to have purchased a site in Pasedena on which it will erect a substation.

BRICEVILLE, TENN. — The Cambria Coal Mining Company, Knoxville, plans to rebuild the power plant at its local properties, recently destroyed by fire.

CLINTON, TENN.—The Knoxville Power & Light Company has petitioned the Federal Power Commission for permission to build a large hydro-electric development on the Clinch River in Scott and Lee Counties, Virginia. The plans call for the construction of four dams on the Clinch River in Tennessee and Virginia.

LAFOLLETTE, TENN.—The Lafollette Water, Light & Telephone Company contemplates extensions and improvements to its hydro-electric plant.

SPRINGFIELD, TENN. — Preparations are being made to enlarge the municipal electric light and water plant. New equipment including a turbine will be installed.

ALBANY, ALA.—Plans are being considered by the Alabama Water Company for the installation of electrically operated pumping machinery, to cost with other extensions about $100,000.

BIRMINGHAM, ALA. — The Alabama Power Company has petitioned the Public Service Commission for permission to extend its electric transmission lines to Waverly, Wetumpka, Centerville and Union Springs.

RUSSELLVILLE, ALA. — Plans have been authorized for a municipal electric light and power plant, to cost about $40,000.

BLYTHEVILLE, ARK.—The Waggoner-Gage Corporation plans to install a power plant in connection with a proposed cotton-oil mill, to cost about $250,000.

LITTLE ROCK, ARK.—The installation of an improved lighting system on Main Street is under consideration by the Merchants' Bureau of the Board of Commerce.

NEW ORLEANS, LA.—The installation of an ornamental lighting system on Magazine Street is under consideration by the Business Men's Associations.

CHICHASHA, OKLA. — The Chichasha Gas & Electric Company plans to erect a high-tension transmission line from Chichasha to Minnekah and Rush Springs.

SAPULPA, OKLA.—Negotiations are under way between the Oklahoma Union Railway Company and the Southwestern Railway Company for the construction of an electric railway from Sapulpa through Keifer to Nuyaka, connecting with the line of the Southwestern out of Bristow, with later extension to Okmulgee and Okemah.

ABILENE, TEX.—Under the terms of a contract between the city of Abilene and the West Texas Utilities Company, an entire new street-lighting system will be installed, including ornamental lamps in the business district and also along the full length of seven residential streets. The cost is estimated at $75,000.

CLEBURNE, TEX.—The installation of an ornamental lighting system is under consideration by the Council.

DALLAS, TEX.—The Dallas Textile Mills Company plans to build a power house in connection with a new cotton mill to be erected in the Love Field industrial district, to cost about $1,000,000. Robert & Company, Atlanta, Ga., are engineers.

DECATUR, TEX.—The Decatur Light & Water Company has installed a 250-hp.

gas-engine-driven generating unit and contemplates extending its high-tension transmission line to the towns of Boyd and Paradise. C. P. Dodson is manager.

FORT WORTH, TEX.—The Transcontinental Oil Company contemplates the installation of electric power equipment in connection with an addition to its local oil refining plant, to cost about $500,000.

TIOGA, TEX.—C. P. Dodson, Decatur, who has recently acquired the local electric plant, plans to rebuild the distribution system and to erect a three-phase transmission line to the Pilot Point plant, which will supply electricity for the system in Tioga.

WACO, TEX.—The Missouri, Kansas & Texas Railway Company has prepared plans for the electrification of its Bellmead car and locomotive shops.

## Pacific and Mountain States

CONCRETE, WASH.—The Superior Portland Cement Company, Seattle, has applied for permission to build a hydro-electric power plant for service at its mills, to cost about $175,000.

MILLWOOD, WASH.—The Inland Empire Paper Company, Spokane, has acquired a power site on the Spokane River for a hydro-electric power plant.

TACOMA, WASH.—The City Council has authorized the installation of an ornamental lighting system on North J Street.

MERCED, CAL.—The Yosemite Cement Company, care of the Hunt Engineering Company, Kansas City, Mo., plans to build a power house in connection with its proposed cement manufacturing plant on the Merced River, to cost about $1,000,000.

MODESTO, CAL.—Bids will be asked at once by the Modesto Irrigation District for the construction of a transmission line to the boundary line of the Turlock Irrigation District. A new substation will be erected at Modesto. R. J. O'Connell is electrical engineer.

ROSEVILLE, CAL.—Work will soon begin on the erection of an ice-manufacturing plant and precooling plant at Roseville by the Pacific Fruit Express Company. The cost of the machinery is estimated at $200,000.

SAN BERNARDINO, CAL.—The Cajon Lime Products Company, recently organized, contemplates the construction of a power house at its proposed lime works near Camp Cajon, to cost about $200,000. W. F. Warner, Riverside, heads the company.

SAN FRANCISCO, CAL.—Plans for the proposed new plant of the Continental Furniture Manufacturing Company, to be erected at Slauson Avenue and Fifty-ninth Street, include a power plant. S. Heiman, 57 Post Street, is architect.

SAN FRANCISCO, CAL.—The California Railroad Commission has approved the contract of the Pacific Gas & Electric Company with the Truckee River General Electric Company, Reno, for the erection by the former of an electric transmission line to the summit of the Sierras, where it will connect with the line of the Truckee company now under construction.

SOUTH PASADENA, CAL.—Steps have been taken for the installation of an ornamental lighting system on portions of Camden and Court Avenues and Huntington Drive.

PAROWAN, UTAH. — Bonds to the amount of $72,000 have been sold, the proceeds of $65,000 to be used for the installation of a new municipal electric light plant.

DILLON, MONT.—The Union Electric Company is erecting a transmission line from Sheridan to Dillon and to erect a substation on Kentucky Avenue, just outside of the city limits.

## Canada

BRANTFORD, ONT. — Extensions and improvements to the street-railway system, to cost about $40,000, are under consideration by the City Council.

BROCKVILLE, ONT.—The Hydro-Electric Power Commission of Ontario is negotiating for the purchase of the Ragged Chute water power on the Mississippi River above High Falls, where electricity is now generated for the Rideau system.

WALKERVILLE, ONT.—The City Council has approved a by-law authorizing an issue of $50,000 in debentures for extensions in the Hydro-Electric system this year.

WALLACEBURG, ONT. — The Hydro-Electric Power Commission of Ontario contemplates the erection of a transmission line from the local substation to Sombra, via Whitebread and Port Lambton, a distance of 16 miles.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued April 24, 1923)

1,452,960. Wireless Transmitter; W. T. Ditcham, Twickenham, England. App. filed Dec. 18, 1920. Inductively coupled type.

1,452,972. Signal System and Transmitter Therefor; R. M. Hopkins, Rutherford, N. J. App. filed Aug. 12, 1918. Fire-signal-transmitting mechanism employed with water-sprinkling system.

1,452,989. Heating Element; N. F. Strauss, Milwaukee, Wis. App. filed April 26, 1921. Liquid acts as conductor between electrodes.

1,453,017. Wall Bridge for Switches; G. H. Lindelof, De Kalb, Ill. App. filed March 22, 1922. Building wall for supporting switches, outlet boxes, etc.

1,453,025. Apparatus for Electric Arc Welding; R. S. Smith, Milwaukee, Wis. App. filed Dec. 6, 1918. Welding of sheet material.

1,453,026. Apparatus for Arc Welding; R. S. Smith, Milwaukee, Wis. App. filed Dec. 6, 1918. Welding of sheet material.

1,453,030. Means for Establishing a Voltaic Arc Between Electrodes not in Contact; F. C. Uear, Madrid, Spain. App. filed July 6, 1915.

1,453,073. Safety Mechanism for Elevator-Shaft Doors; G. G. Laureyns, Newark, N. J. App. filed Dec. 3, 1919. Lock on door magnetically operated by elevator as it comes to floor level.

1,453,083. Electric Machine; M. Schuler, Neumuhlen, near Kiel, Germany. App. filed Oct. 25, 1916. Hydrogen gas used to ventilate that placed in inclosed-tank machine.

1,453,097. Multiple-Unit Induction Furnace; C. B. Foley, Bristol, Conn. App. filed Dec. 28, 1916. Induced secondary formed by metal within crucible.

1,453,132. Process for the Recovery of Pure Alkalies from Impure Lyes; K. Heinemann, Heldenau, Germany. App. filed Nov. 8, 1920. By electrolysis.

1,453,159. Cooling of Dynamo-Electric Machines; P. A. H. Mossay and H. C. E. Jacoby, London, England. App. filed Jan. 16, 1919. Cooling system for totally inclosed motors.

1,453,166. Rotary Electric Machine; K. Nobuhara, Muko-Gun, Hyogo-Ken, Japan. App. filed Oct. 23, 1919. Machine filled with liquid, air being used to force liquid from gap.

1,453,173. Electric Wire Clamp; P. Pairard, Paris, France. App. filed June 13, 1918. For fastening wires to pin insulators.

1,453,194. Dental-Film Holder; A. E. Shaw, Columbia, S. C. App. filed April 26, 1922. For X-ray machines.

1,453,195. Signaling Mechanism; J. C. Sims, Maynard, Mass. App. filed Nov. 6, 1919. Electrically operated visual and sounding signal.

1,453,201. Strain Insulator; L. Steinberger, Brooklyn, N. Y. App. filed Nov. 30, 1918. Exposed bridge portions insulated from leg portions.

(Issued May 1, 1923)

15,594 (reissue). Signal for Vehicles; T. B. Powers, Brooklyn, N. Y. App. filed Aug. 11, 1919. Rear direction signal.

1,453,267. Electron Emitting Cathode and Method of Making the Same; J. L. Bradford, New York, N. Y. App. filed Nov. 29, 1918. For electron tubes.

1,453,314. Current Regulator for X-Ray Systems; C. Fayer, New York, N. Y. App. filed April 2, 1918. Employed with Coolidge tubes.

1,453,316. Acoustic Method and Apparatus; R. A. Fessenden, Brookline, Mass. App. filed April 28, 1919. Submarine signaling.

1,453,321. Call-Distributing System; W. S. Paca, Oil City, Pa. App. filed Sept. 4, 1919. Applied to the operation of manual telephone exchange.

1,453,328. System of Ventilation; J. Smillie, Stretford, Manchester, England. App. filed Nov. 12, 1920. Closed-circuit system of generators.

1,453,333. System of Ventilation; K. Baumann, Urmston, England. App. filed Oct. 9, 1920. Closed-circuit system for generators.

1,453,343. Welded Joint; J. W. Fay, Milwaukee, Wis. App. filed Dec. 19, 1921. Method of making reinforced joint between two plates.

1,453,347. Electric Furnace; A. W. Gregg Chicago, Ill. App. filed July 11, 1921. For melting small quantities of material by electric arc.

1,453,349. Lighting Fixture; E. F. Guth, St. Louis, Mo. App. filed May 29, 1920. Indirect fixture for high-powdered lamps.

1,453,357. System of Ventilation; J. E. Jolly, Stretford, Manchester, England. App. filed Oct. 6, 1920. Closed-circuit system for generators.

1,453,358. Process of Joining Metals; C. F. Kettering, Dayton, Ohio. App. filed Dec. 15, 1920. Attachment of non-ferrous metal-cooling elements (such as copper fins) to cylinders of internal-combustion engines.

1,453,359. Telegraph Sounder; J. H. Kinsley, Clinton, Mass. App. filed March 27, 1920.

1,453,368 and 1,453,369. Speed Regulator for Automobiles; F. W. Teves, East Elmhurst, N. Y. App. filed Jan. 25, 1922. Automobile cannot exceed predetermined speed limit.

1,453,387. System for Communicating with Moving Vehicles; L. Espenschied, Hollis, and H. A. Affel, Brooklyn, N. Y. App. filed Sept. 30, 1919. High-frequency current line from which signals are taken parallels tracks.

1,453,388. Electrolytic Condenser; C. Le G. Fortescue, Pittsburgh, Pa. App. filed Nov. 3, 1919. Insure maximum area of heat radiation.

1,453,389. Arc-Welding Dynamo Electric Machine; K. L. Hansen, Wilkinsburg, Pa. App. filed Sept. 25, 1919. Constant-current generator employed in direct-current welding systems.

1,453,391. Alternating-Current Commutator Generator; R. E. Hellmund, Swissvale, Pa. App. filed Aug. 10, 1918. Stabilizing commutator motor for regeneration.

1,453,397. Protection of Resistors of Electric Furnaces; G. M. Little, Pittsburgh, Pa. App. filed April 21, 1921. Sooty oil flame deposits protection coating on resistors.

1,453,398. Self-Tightening Water-Cooled Terminal; G. M. Little, Pittsburgh, Pa. App. filed April 21, 1921. For electric resistance furnaces.

1,453,399. Means for Protecting Resistors in Electric Furnaces; G. M. Little, Pittsburgh, Pa. App. filed April 25, 1921. Oil forced into furnace deposits sooty coating on resistors and furnace walls.

1,453,410. Dynamo-Electric Machine; J. Slepian, Wilkinsburg, Pa. App. filed Dec. 17, 1919. Elimination of transformer and rotational electromotive forces of armature coils undergoing commutation.

1,453,412. System of Control; G. F. Smith, Wilkinsburg, Pa. App. filed Sept. 25, 1919. Regenerative braking of electric railway motors.

1,453,419. Electroplating Apparatus; W. Thompson and W. R. Jameson, Niagara Falls, N. Y. App. filed Sept. 12, 1921. For manufacture of knives, forks, spoons, etc.

1,453,430. Voice-Operated Relay; O. B. Blackwell, Garden City, N. Y. App. filed Nov. 22, 1919. Two-way repeater communication system.

1,453,435. Method and Apparatus for Nitrogen Fixation; C. H. Buettner, Cincinnati, Ohio. App. filed Nov. 17, 1921. Calcium or potassium nitrate made at place where they are to be applied to soil.

1,453,441. Excess-Demand Meter; G. A. Cheetham, Manchester, England. App. filed Oct. 6, 1920. Method of releasing indicating lever periodically.

1,453,442. Marking Machine; W. E. Choate, Westerly, R. I. App. filed April 26, 1921. Machine adapted to make impressions from electrically heated typed members or dies.

1,453,443. Lighting Fixture; W. E. Cochran, Cleveland, Ohio. App. filed June 1, 1920. Indirect lighting type.

1,453,453. Notifying or Call Device for Telephones; G. Forster, Philadelphia, Pa. App. July 24, 1920.

1,453,473. X-Ray Plate Changer; R. J. McKenna, Denver, Col. App. filed Feb. 23, 1922. Tunnel type.

1,453,491. Voltage-Regulating System; F. J. Champlin, Pittsfield, Mass. App. filed March 22, 1921. Induction regulator.

1,453,492. Overload Circuit Controller; C. B. Connely, Scotia, N. Y. App. filed Aug. 2, 1921. Overload relay.

1,453,498. Maximum-Demand Meter; W. L. Hamilton, Holyoke, Mass. App. filed Aug. 25, 1919. Curve-drawing type.

1,453,522. Control of Dynamo-Electric Machines; H. W. Rogers, Schenectady, N. Y. App. filed Oct. 6, 1922. Control of Ward Leonard motor-generator sets.

1,453,524. Wire Splicer; F. A. Ropp, Smithton, Pa. App. filed June 16, 1922. Clamping device for connecting ends of trolley wires.

# Pre-eminence of New York in Use of Electricity

THE pre-eminence of New York City in the Western Hemisphere is beyond all cavil or question. Faith, learning, character and competence in business have brought her this distinction. Among all the cities of the world also she fills a role peculiarly hers. This applies to her harbor, her towering buildings, her public works and also to her system of electrical supply. Not that the latter exceeds in efficiency other large systems, for no city has a mortgage on all science, initiative, genius or brains; but by reason of its teeming population and restricted area more electricity is used in New York City than in any other city in the world.

Those who attend the convention of the National Electric Light Association, if they seek, will find hidden treasures of applied electricity on all sides. Outwardly the manifestations are scarcely visible except at night, for there are no wires to be seen overhead and, indeed, there is hardly enough space to spare for them underground, so encumbered is the earth with subways, water pipes, gas mains, sewers and the myriad cables of the telegraph, telephone and electricity supply companies.

The accounts given in this issue of the features of the various generating systems are necessarily brief. A volume could be written about the precautions taken to guarantee service alone, for the railroads, the street railways and even the isolated plants in every emergency caused by mishap to their own systems cast their loads on the mains of the central-station companies. And the wonderful thing about it is that the latter have never failed them. But there are other phases of the electricity supply business just as exacting and just as interesting to both engineers and executives which will repay investigation.

As for growth, the new building program of New York is so immense that the electric light and power companies are hard pressed in extending their mains and installing the service. Few companies can show larger increases in new meters connected or in accretions to gross revenue, and there are no signs of let-up. Clear perception of the facts is necessary for a just appreciation of the work of the electric light and power companies in the metropolitan district. Bigness is one chief characteristic; the unostentatious self-confidence and apparent ease with which great results are accomplished is another.

# Editorial Comment

Electrical World, May 26, 1923

Volume 81 Number 21

## Progress Unimpeded, Growth Prodigious

THE N. E. L. A. convention of 1923 will long be remembered because it fell in a year which saw the beginning or the completion of so many great electric power houses. Readers of this paper are familiar with the tale of Crawford Avenue piled on Calumet, of Trenton Channel doubling Connors Creek, of Hudson Avenue added to Gold Street, of Kearney o'ertowering Essex, of Devon and Weymouth, Delaware and Saxton, Cahokia and Philo, High Bridge and Zilwaukee, Peoria and Wabash, of Niagara and Pit River, St. Croix and Boulder and Mitchell Dam—the list of familiar names could be extended almost indefinitely.

As estimated in a tabulation appearing in News of the Industry this week, the largest steam and hydro-electric stations under way or just completed, together with extensions to existing stations, reach a total rating of 3,500,000 kva. and a total cost of approximately half a billion dollars—and the innumerable small stations all over the land are not included.

The convention of such an industry as this in such a year as this cannot but be full of interest, of enthusiasm and of profit. With such prodigious growth, such unimpeded progress, there are problems worthy of the best of men to solve. The annual convention of the N. E. L. A. assists in no small measure not only the individual's own accomplishments but the collective or group action so necessary in the proper progress of the industry. The convention this year cannot help but be memorable. Every one who can should attend.

## Reproduction Cost as an Element in Valuation

ONCE again the United States Supreme Court has declared that no adequate determination of fair value can be arrived at without due consideration being given to reproduction cost on the basis of present-day prices. The latest pronouncement of the court in this regard is embodied in a decision in the case of the Southwestern Bell Telephone Company of Missouri handed down on Monday of this week. But it should also be noted that the Supreme Court does not hold that reproduction cost alone is the measure. In fact, the words of the court—"An honest and intelligent forecast of probable future values, made upon a view of all the relevant circumstances, is essential"—sound in tone much like those used in the famous case of Smythe vs. Ames, when the court said:

> . . . The basis of all calculations . . . must be the fair value of the property. . . . The original cost of construction, the amount expended in permanent improvements, the amount and market value of its bonds and stock, the present as compared with the original cost of construction, the probable earning capacity of the property under the particular rates prescribed by statute, and the sum required to meet operating expenses, are all matters for consideration and are to be given such weight as may be just and right in each case. We do not say that there may not be other matters to be regarded in estimating the value of the property.

Justice Brandeis, in a separate opinion, urges the money invested in the enterprise as a preferable basis, asserting that advocates of reproduction cost will find its application harmful when wages and costs are lower. The important element in the majority decision, however, is that "all relevant circumstances" must be considered, and important among these is "reproduction cost on the basis of present prices," which must not be neglected. This latest decision is another encouraging pronouncement in the long string of Supreme Court findings which uphold the rewards of private initiative and guard against confiscation.

## Again the Question "How Do You Find Business?"

IT IS not hard to think back just a few short years to the days when business men on every side were asking each other the question "How do you find business?" Then the country was just pulling out of the valley of depression into the cheerful prospect of returning prosperity. Each one sought to bolster up his returning confidence with the courage of his fellows. Now again comes the query—repeated on every side. But the reason is somewhat different today. Prosperity and expansion have rolled up a wondrous record of late, and men are asking each other if it will continue.

The matter lies surely in the hands of those who themselves are asking the question. Blinded with greed for still greater profits, capitalists, manufacturers and merchants in the post-war boom kept on raising prices until the people would endure no longer, and a buyers' strike and the disastrous slump in business followed. Whether this bit of history is to repeat itself will depend much on whether the American business man will remember the lesson that he learned so painfully and refrain from imposing on the public.

The prosperity of the electrical industry depends upon the prosperity of industry in general, and all prosperity naturally is the sum of the success of individuals. The responsibility for protecting general business against a setback similar to that of recent memory devolves upon business men, merchants and manufacturers as individuals. If they too long forget their duty to the public, crowd on the profits and force up prices, reaction will inevitably come. If they temper their zeal with caution and with prudence, there need be no disappointment. The central-station business is one in which no such danger or, indeed, opportunity of pyramided prices exists. But central-station men as well as other electrical men can exert a sobering influence and help strengthen public sentiment for moderation in profit making in every community.

### Wet-Flashover Tests Not Susceptible of Close Control

A GOOD many engineers who comment on the standard pin-type insulator ratings proposed by the American Institute of Electrical Engineers ask why dry-flashover voltages should be used as the basis and wet-flashover voltages ignored. The selection is based on the very practical fact that the wet-flashover test under any known test conditions is not susceptible of close enough control to make its use feasible for such a purpose. The area over which water must be distributed in making such a test is small, but experiments to determine the uniformity of distribution of moisture show that even in such a small area, with the best means of spraying that can be designed, the distribution is surprisingly bad. There seems to be little hope of devising a practical method of keeping this factor under better control. Another important reason for the decision is the resistance of the water used in the tests. Large quantities are required. As an economic proposition it is impracticable to use water that has been treated to bring it to a standard condition of resistance and to maintain it in that condition for an indefinite time. As a result of these two difficulties wet tests made under apparently identical conditions vary too widely to permit their use as a basis of rating.

The dry test has been proved capable of close control as to conditions and results. Consequently it was selected as the basis for pin-type insulator ratings. The wet-flashover test, however, has a very definite value as a design check test, and the committee has presented a proposed standard for consideration.

### Why Not Take a Hint from Nature?

THE fierce sleet storms which overwhelmed forests and overhead lines in some parts of the country a year and a half ago left a shaky feeling in the minds of system operators lest even worse trouble come upon them. The sleet question is a queer one, not easy to reduce to formulas. Sleet seems to flourish especially in the climate of the northern United States—it is almost unknown in continental Europe—and the vital problem for designers of lines, poles and towers is to find out how, if at all, designs can be modified to gain comparative immunity from failure while still keeping within the limits of practical expense.

It would be interesting to know how many transmission-line operators have taken full cognizance of what happened to trees. The story of their destruction and successful defense ought to bring home a lesson to those who are building artificial structures to meet the same kind of stresses. In the worst of the devastated area the appalling combined effect of sleet and wind was evident everywhere. Big oaks and hickories snapped like pipestems under the load and branches were ripped off from the treetops down; maples and elms and other supposedly sturdy trees went to wreck at a moment's notice. But with it all the conifers escaped material damage. Thick though their foliage was, carrying the load of tons of ice, these great trees, engineered by nature on the principle of flexibility rather than stiffness, simply folded up their overburdened branches like the ribs of an umbrella and waited for the thaw to come. Then they shook off their icy burden and returned substantially unharmed to their original straightness and dignity.

Could something of this lesson be more often applied to overhead lines, particularly those which do not have outrageously severe loads of copper to carry? A little thought and study of how to obtain the maximum of elastic strength rather than the maximum stiffness would go far toward making a line of greater utility, although perhaps less attractive to the eye than many of the forms now in use. It is, after all, merely a matter of distributing the load so that it shall in a measure equalize itself before disaster comes.

### Power-Factor Correction a Commercial Problem

IT TOOK considerable time to convince central-station executives that a power factor meant decreased ability to serve and increased cost of operation. The growth of systems and the increased demands for power, however, presented specific facts that were sufficient to prove the case. For example, when voltage drop determines line loading and a specific line can carry double the load at unity power factor that it can at 70 per cent power factor, this fact becomes important financially if corrective equipment can be used more cheaply than duplicate circuits can be built. Thus an array of facts and figures proved to central-station executives that a low power factor makes overhead costs higher, increases production costs, limits the return from existing installations and reduces the general efficiency of the service.

Once convinced of the economic advantages of a good power factor, the executives called in the operating and commercial departments and ordered them to improve the power factor on the system. Easily said and easily analyzed on a theoretical basis, but difficult to accomplish commercially. Rate clauses containing penalty or bonus features, some ill-judged selling of corrective equipment to customers, new metering devices and accounting methods were some of the steps taken. But the fundamental thought was not emphasized that the customer must be "sold" on the benefits *he* would derive from power-factor improvement, and the results on the whole were not very satisfactory. Only recently has some new thinking been done to obtain real results with power-factor correction.

In the first place, the attention of the customer must be taken from power-factor rate clauses and focused on the real advantages of power-factor correction which will result in financial saving for his installation. In the second place, a thorough study and analysis of every proposed installation must be made to gather data on motors, circuits, operating requirements and energy consumption. Frequently these data will permit of rearrangement of the motors or rewiring to an extent that will be very beneficial both from an operating and an improved power-factor standpoint. In all cases the data are needed to show the decrease in circuit losses, the increase in motor efficiencies and the greater reliability of production and greater speed that can be obtained with a higher power factor. Once these items are capitalized to the customer in dollars and cents, he is willing to go further in considering power-factor corrective devices. Then the problem is to use the proper corrective equipment and the proper rate clause to obtain the results desired both by the central station and the customer. This problem is becoming increasingly less difficult because of the developments occurring in the industry. Thus power-factor correction is best obtained by properly "selling" the customers and by

getting away from the tradition long held by both manufacturers and central stations that a low power factor is inherent in the alternating-current system.

### Liberal as Well as Technical Training

DISCUSSION as to the most advantageous forms of educational training for the profession of engineering has for a long time indicated a realization on the part of educators, engineers and industrial employers that for many types of engineering problems far more is requisite in the way of formal training than is possible in the usual four years' undergraduate course. The additional needs are twofold, one in the direction of a wider general education, fitting for prominent participation in the economic and political phases of engineering discussion, and the other for more extensive training in special engineering fields, with a knowledge of pure science fitting for experimental research.

In response, first thought and suggestion have indicated the addition of the graduate school to the usual undergraduate curriculum. Several of the more prominent schools have for a long time announced and conducted graduate courses leading to advanced degrees. Apparently, however, attendance in these graduate courses has not been large, and it appears difficult to induce the four years' undergraduate to go on. In spite of scholarships and fellowships of steadily increasing value, the call of the industrial field, with a good living wage at the start, is more attractive than the prospect of two or three years more of intensive mental effort and, usually, rigid personal economy. Another reason, it is to be feared, is the lack of vision and inspiration of the average teacher of engineering subjects. Too often he is himself a four-year man, and his conception of the sphere of the engineer is limited to the normal processes of operation, routine design and industrial production. He is often incapable of holding up to the student the wide opportunities open to the engineer as a participant and agent in the large enterprises of social, civic and political life, as well as in the great field of engineering research. Apparently, the young man entering the usual four years' course somehow acquires at an early stage an idea that the highest aim and greatest rewards of the profession are open to him when he takes the bachelor's degree and receives an invitation to a beginner's job from a manufacturer's scout.

This is not to say that any large proportion of these four-year men should be encouraged to go further in formal training. The industries need them by the thousand each year, and not many of them are fitted for the advanced field. But a select few, and more than at present, should advance through the discipline of graduate study to the rank of the highly educated man, as well as that of the thoroughly trained engineer. Or, equally desirable, the prospective student of engineering should first take the liberal courses leading to the degree of bachelor of arts and then begin his professional studies. Some years ago Harvard adopted this plan for all students of engineering, but abandoned it after a few years; the plan was well conceived but too long a step in advance. For several years Columbia has been trying an intermediate plan in requiring two years of general college work for admission to her three-year courses in engineering, and the experiment is being watched with interest. A somewhat different method is found in the recent announcement by Johns Hopkins of combined courses in the liberal arts and engineering, in which certain fundamental courses necessary for engineering, such as applied mechanics and the like, are accepted as electives for the degree in arts and the combined time for both degrees, in the arts and in engineering, is shortened to five or six years. This type, of course, has been available for several years in a few Middle Western schools, yet only a few young men availed themselves of the opportunity offered. The plan seems to have the advantage of an easy transfer to the study of engineering, without wasted effort, by a student who is well advanced in courses in the liberal arts, and so has more of the desirable broad and fundamental education. These steps are indications that a few individual institutions are convinced of the importance of more liberal training for certain types of engineers and are willing to make the effort to train them. Perhaps only a few such courses are needed.

### Inspectors May Take Advantage of 1923 Code Changes

IT SEEMS unfortunate if, for a simple matter of expediency, the benefits of the recent revisions of the National Electrical Code are to be officially withheld from the public for several months. As pointed out in the ELECTRICAL WORLD in its issue of May 5, there are many reasons why the changes in the code should be made available for application at the earliest possible moment. They were worked out after long and thorough consideration and represent an advance in the code of no small importance and value.

It is, of course, easy to understand that the rearrangement and rephrasing of the code on account of the changes involved is not a small matter and is necessarily a somewhat slow process; but if the previous practice of the electrical committee is followed in this case, namely, to discourage the application of code changes until the revised edition can be printed, a delay of some consequence is involved. Some of the revisions are less restricted, some are more restricted, but all are in the public interest, and those who are building should have the advantage of the changes while building is going on.

It should be understood, however, that the actual final authority to place the changes into effect rests with the inspectors of the various districts. The code and its changes are essentially recommendations. The committee feels that it would exceed its authority if it sent out advance digests of the changes in the code, but its chairman, Dana Pierce, suggests that the ELECTRICAL WORLD reprint its statement of the code changes originally printed in the March 24 issue and furnish it to all inspectors who may desire copies. Such inspectors would then be in a position to use their admitted right to apply the new code.

Under the circumstances this seems an advisable move to make, and the ELECTRICAL WORLD will be glad to send without charge to any inspection authority who may desire them copies of the condensed statement of the 1923 code changes approved by Mr. Pierce at the time it was published as giving in essence the principal alterations. This at least provides a means for inspectors to have the code changes available now and to put them into practice in their districts at their discretion.

The Metropolitan District of New York, Showing the Financial Center of the World and New York Harbor

# Character of Metropolitan Service

## Enormous Output of Electrical Energy in the New York District and Precautions Taken to Safeguard the Supply—Cities and Industries Depend on Central-Station Service—Tremendous Loads Thrown on System Suddenly

THE metropolitan district of New York includes not only the area within the corporate limits of the central city but also parts of the surrounding territory which are closely associated with the development of the metropolis. The city itself has an area of 183,555 acres and a population of 5,620,000, or 5.31 per cent of the entire population of the United States. Outside and within the metropolitan area are the counties of Nassau and Westchester in New York and the counties of Bergen, Essex, Hudson, Middlesex and Union in New Jersey. These have a combined population of approximately 2,500,000, giving to the metropolitan district almost 8 per cent of the entire population of the country. This district ranks first among the metropolitan districts of the United States in the value of its products.

The quantity of electricity generated in the New York district for all purposes in 1922 was fully six thousand million kilowatt-hours, with a peak load of approximately 1,500,000 kw. and a load factor hovering around 40 per cent. Of this amount the isolated plants in the hotels and some of the office buildings of New York City and those in the large industrial districts of New Jersey contribute over a thousand million kilowatt-hours yearly. The outputs and peaks of the public utility companies in 1922 are shown in Table I, in which no account has been taken of the outputs of the smaller generating companies in the boroughs of Richmond, Brooklyn and Queens or in the New Jersey districts.

TABLE I—OUTPUTS AND PEAKS OF METROPOLITAN UTILITY COMPANIES

| Name of Utility Company | Output in Kw.-hr. | Peak Load in Kw. |
|---|---|---|
| New York Edison Co. and United Electric Light & Power Co. | 1,659,269,781 | 497,577 |
| Public Serviee Electric Co. | 958,407,194 | 249,778 |
| Brooklyn Edison Co. | 516,987,870 | 164,495 |
| New York & Queens Electric Light & Power Co. | 120,011,093 | 35,300 |
| Interborough Rapid Transit Co. | 886,223,920 | 246,770 |
| Brooklyn Rapid Transit Co. | 413,992,125 | 118,800 |
| Pennsylvania Railroad Co. | 214,906,725 | 72,000 |
| New York Central Railroad Co. | 157,450,819 | 48,470 |

### Leading Industries of New York

While it is universally known that New York is the largest city in the Western Hemisphere, it is not generally appreciated that its population is almost as large as that of the State of Ohio, the fourth most populous state in the Union. Brooklyn, for instance, has a larger population than the city of Philadelphia; Manhattan and Queens exceed Chicago by 40,000; the Bronx is as big as Baltimore, and Richmond is more populous than Nashville or Salt Lake City.

Industrially the city also leads. The essential facts concerning New York's manufacturing industries are shown in Table II.

New York leads the country in the production of many items in common use and manufactures a very large proportion of many others. This is particularly true of outfitting and apparel. For the women who make their own clothes, for instance, New York produces 95 per cent of all the paper patterns made in this country, and for the women who wear ready-made clothes New York produces nearly three-quarters of the country's entire output. The same is true of fur goods. New York also makes about one-half of the country's output of millinery and lace goods. In the city are cut and polished 90 per cent of the diamonds and other precious stones which are manufactured in this country. One-third of the country's jewelry is manufactured in New York and about 30 per cent of the nation's production of pianos.

For men New York makes four out of every ten ready-made suits of clothes, 46 per cent of furnishing goods, 40 per cent of the shirts and a quarter of the hats. It also supplies them with four out of every five tobacco pipes made in the country. New York is the greatest printing and publishing center of the country. It makes 29 per cent of the toys and games, a third of the mirrors, a quarter of the buttons, chewing gum and scientific instruments, and a large percentage of the patent medicines and compounds manufactured in the United States. In addition to all these is the fact that New York is now the financial center of the world.

### Problem to Find Space for Wires

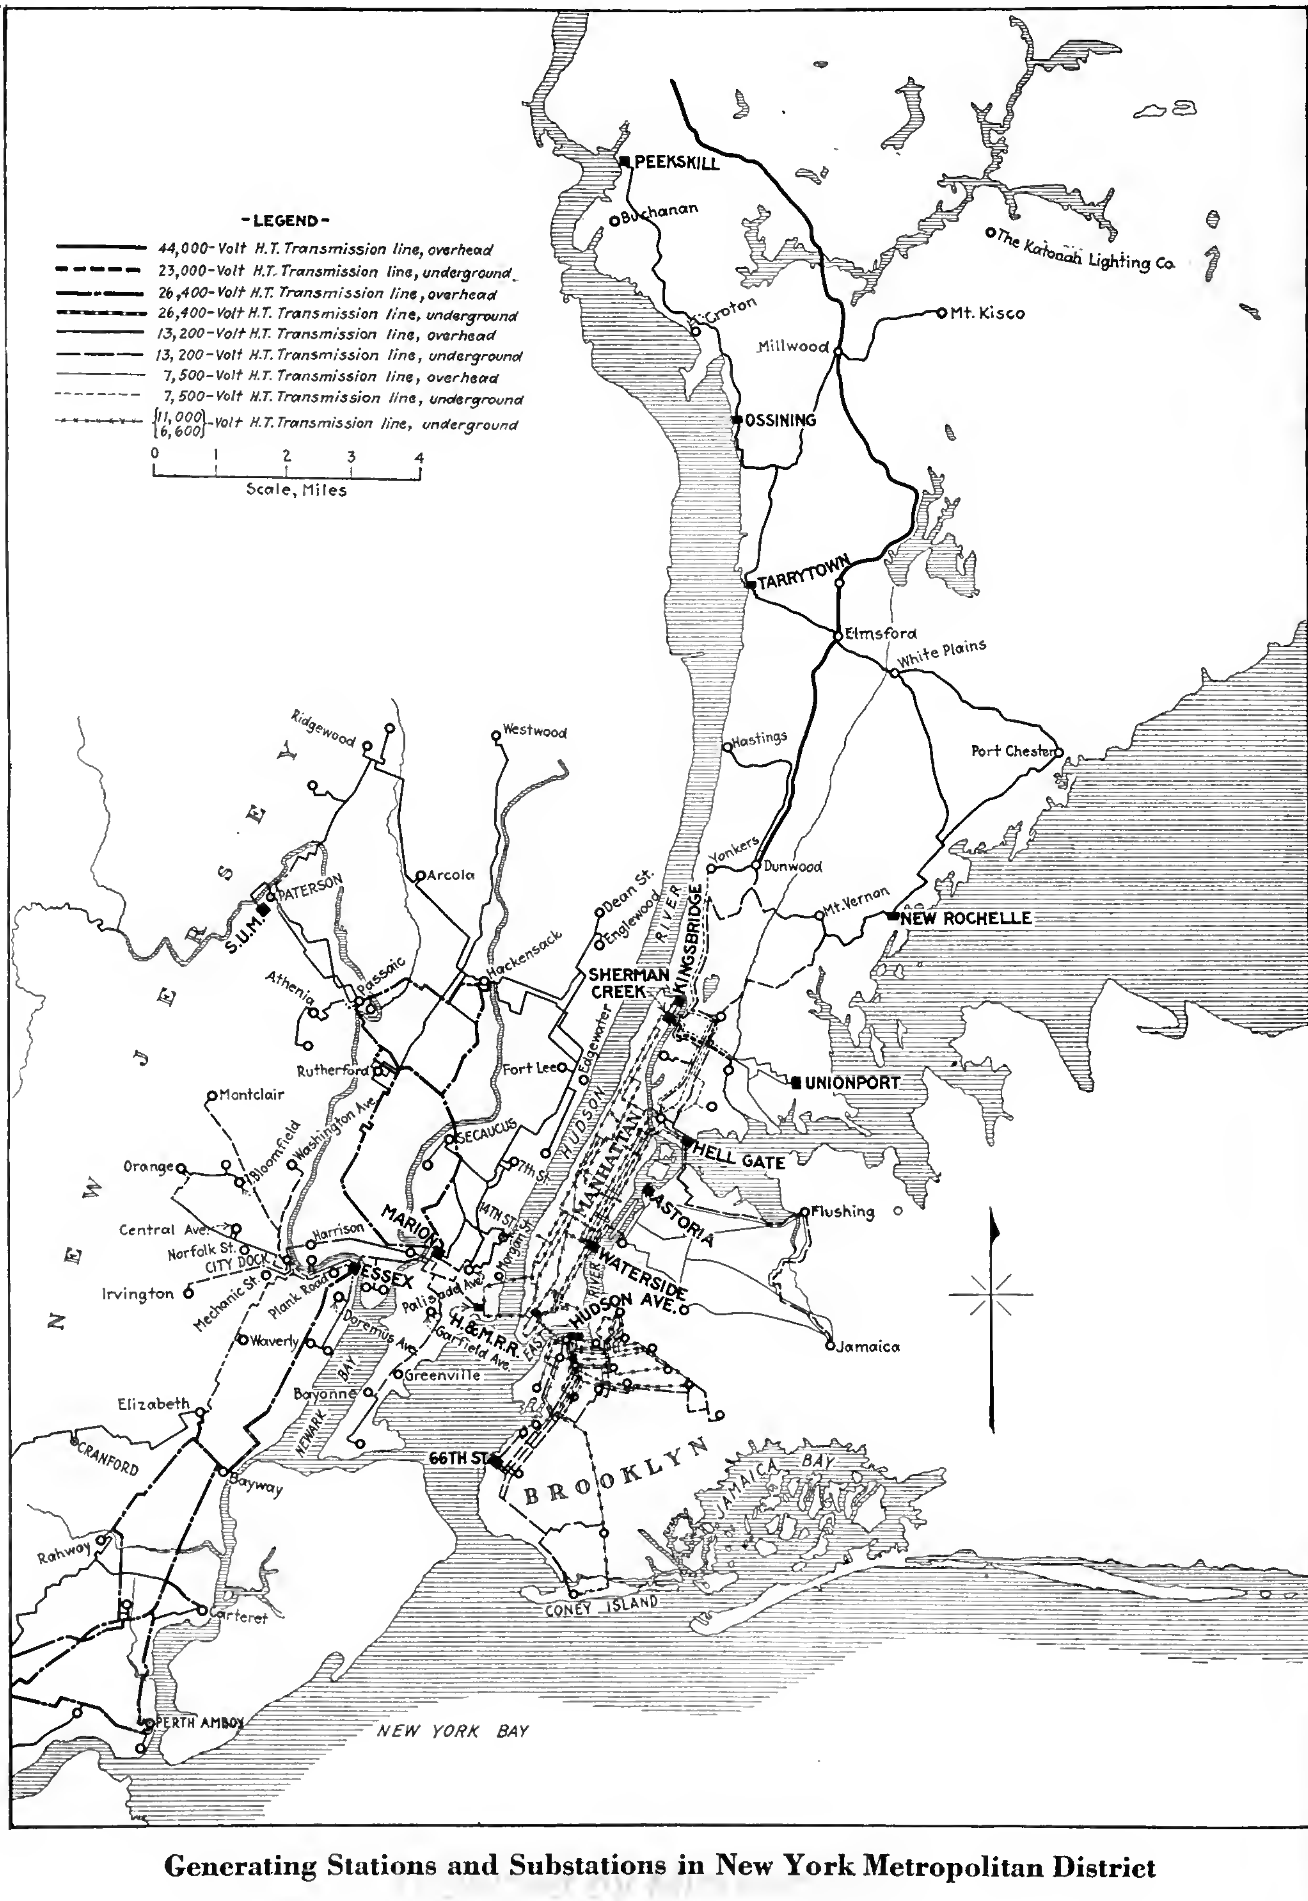
In a district the size of New York, with so many diversified and varied industries and with such a compact population working in skyscrapers and living in huge apartment houses, naturally electricity plays a very important part, more important than in any other city in the world. Without it the immense subway system of passenger transportation would be impossible, skyscrapers and large apartment houses and hotels would be largely uninhabitable, Broadway would become a village street, and a large part of industry would have to move elsewhere.

Having such a vital part in the life of the city, every precaution is taken to safeguard the supply of electricity and to provide for continuity of service. No overhead wires are permitted in the Borough of Manhattan, so that distribution of all electric service there is underground. So intensive is the use of electricity in many of the districts of Manhattan and so occupied are the streets with subways, pipes and ducts that the limit of capacity of many of the substations is fixed by the space available for underground cables in the streets. In the congested districts the situation is causing the operating companies much concern.

TABLE II—MANUFACTURING DATA FOR NEW YORK CITY

| | |
|---|---|
| Number of establishments | 32,590 |
| Persons engaged in manufacturing industries | 825,056 |
| Capital | $3,038,557,492 |
| Salaries and wages | 1,131,994,192 |
| Value of products | 5,260,707,577 |
| Value of raw material used in manufacture | 2,801,619,388 |
| Value added by manufacture | 2,399,231,459 |

All of the generating stations in New York are interconnected, and the practice in Manhattan is to feed the substations from independent generating sources. More equipment could be installed in the generating stations of The New York Edison Company if sufficient space



Generating Stations and Substations in New York Metropolitan District

could be found in the streets for the copper feeders. As it is, lack of street space has limited the interconnections between generating stations and between generating stations and substations even though the distribution voltage has been raised from 6,600 to 11,000 and tie feeders between stations are being operated at 40,000 volts.

### IMPORTANCE OF ELECTRIC SERVICE

The reasons why continuous electric service is imperative in the Borough of Manhattan will be apparent from the following considerations: The high-pressure pumping stations of the fire-protection system are absolutely dependent on central-station service for their operation not only in the Borough of Manhattan but in the Borough of Brooklyn as well. Any interruption lasting over three minutes is penalized at the rate of $400 a minute, but no penalty has so far been collected in either borough. The police and fire-alarm signaling systems, the ticker system, the telephone and telegraph systems of the Bell, Western Union and Postal companies, the trans-Atlantic cable companies, the newspapers, the garment and needle trades, 95 per cent of the passenger and freight elevators of the borough and the entire street-lighting system depend solely on the electric service of The New York Edison Company.

In order to provide a service which shall be at all times available great precautions must be taken. Coal shortage because of strikes or other reasons is guarded against by storage at Shadyside, N. J., and at the Hell Gate station, in addition to the overhead bunkers in the generating stations themselves in the case of the New York Edison and United companies. Space is available for more than 300,000 tons of coal, and during the recent coal crisis large cargoes of coal were imported from England. Taking into consideration the cost of the real estate and equipment and the cost of the coal in storage, the amount of working capital tied up in coal storage alone is not far short of $5,000,000 for the Edison company. In addition, to guard against any emergency or failure of generating equipment The New York Edison Company has electric storage batteries whose one-hour discharge rate is 471,000 amp. and from which 250,000 kw. can be pumped into the system for fifteen minutes.

The downtown section of New York is built skyward. There structures unequaled in height in any other section of the world are built wall to wall as compactly as possible. Each is a city in itself, with its vertical traction system in the shape of elevators, with a complete water supply and sewerage system and with power and lighting loads exceeding those furnished by many towns of like population. So high are these buildings that the streets resemble canyons more than thoroughfares, and electricity must be used for lighting the lower offices even during the day.

Such a condition is not without its effect on the electric light and power company, particularly when sudden storms sweep over the city. Every precaution is taken to have the power houses ready for such emergencies, and warnings are telephoned to operators when lowering clouds appear. The peaks thrown on the system are oftentimes of short duration, but to meet them means eternal vigilance and tremendous cost.

One such peak occurred at 4 p.m. on March 2, 1911, when an extra 52,000 kw. came on the system, which in five minutes was carrying a load of 75,000 kw., the extra load disappearing during the following ten minutes. The cause was a snow squall from the Northwest. On June 20, 1919, about 3 p.m., when the system was carrying 180,000 kw., a thunderstorm added 133,000 kw. to the load in about thirty minutes, and this extra load did not entirely disappear until 5 p.m. The total load overtopped the winter peak by 15,000 kw. In this case about 40,000 kw. was carried by the storage batteries for a few minutes. Similar in its effects to the thunderstorm peak, but not so troublesome, is the dark day. On Feb. 28, 1923, the load on the system increased from 120,000 kw. to 435,000 kw. in two and one-half hours, an increase of nearly 3,000 kw. per minute, and this load persisted for more than eight hours. One can readily appreciate the great reserve capacity required in an electric supply system capable of handling such tremendous loads on such short notice without any indication of distress.

### MORE THAN A MILLION METERS INSTALLED IN CITY

The practice of selling electricity in New York differs somewhat from that which obtains in other cities in that dwellers in huge apartment houses are customers of the landlord rather than customers of the company. Thus the number of meters actually owned and installed by the utility companies represents less than the total number of users of electric service. There are in the Borough of Manhattan alone more than 150,000 sub-meters in apartment houses, service to which is supplied by the public utilities through a master meter.

The total number of meters connected to the circuits of the utility companies in the greater city was, at the end of March, 889,946, which, plus the sub-meters installed in apartment houses, brings the total number of electric meters in use to considerably over one million. As all of the distribution circuits on Manhattan are underground, and underground construction on Manhattan means blasting from solid rock, it will be appreciated that the cost of servicing a customer is high. Notwithstanding this fact, there is no minimum service charge for energy in Manhattan and the Bronx, and The New York Edison Company has on its circuits more than 50,000 customers whose annual bills for electrical energy are less than $10 a year.

The number of new meters which are being added to the circuits of the companies in Brooklyn, Queens and in the New Jersey district is very great. The Public Service Electric Company of New Jersey, for instance, connected 63,901 meters to its system last year, as compared with 45,912 in 1921, and of these 83 per cent were small meters for domestic service. The Brooklyn Edison Company in a smaller district during the same period added 63,657 new meters, a gain of 26 per cent over 1921. The ratio of growth in the Borough of Queens is even larger, the New York and Queens Electric Light & Power Company, which has almost 100,000 meters on its circuits, having increased their number during the last ten years 1,400 per cent.

### EXPENDITURES FOR EXTENSIONS AND ADDITIONS

Of course, enormous expenditures have been made and are being made by the electric public utility companies to keep abreast of the demands made upon them for service. Since 1916 The New York Edison Company and its subsidiary, The United Elec'ric Light & Power Company, have expended more than $70,000,000 for additions and betterments to the system. This company, which has the largest gross income of all of the purely electric light and power companies of the country, will, at the present ratio of increase, which is

over 16 per cent, have a gross income of more than $60,000,000 this year. The Brooklyn Edison Company has increased its gross revenue in five years 135 per cent, and the gross earnings of the company for the four months ended April 30, 1923, showed an increase of $2,000,000 over the same period last year, or an annual rate of increase of $8,000 000. The gross earnings last year amounted to $19,129,000 against $16,000,000 in 1921. Since 1921 the capital of the company has been increased from $19,000,000 to $50,000,000.

The large increase in business reflects the fact that new construction in Brooklyn is going ahead at a pace equaled by few cities in the United States. During the first four months of the year the Brooklyn Edison Company added 22,000 new customers, and May showed no diminution in the rate at which new names were being added to the books. At the first of this year the expansion program of the Brooklyn Edison Company, to meet increasing demands for service, called for an expenditure of about $15,000,000, while $7,000,000 had been expended out of earnings for this purpose during the previous year. The expansion program includes a new 400,000-kw. steam station on the East River at Hudson Avenue. This station when completed will be one of the largest in the country.

Other features of the generating systems in the metropolitan district are given elsewhere in this issue.

# Edison and United Companies' System

## Manhattan Island Has the Most Concentrated Load of Diversified Character to Be Found in the United States—Service in the Bronx and Westchester and Connections with Railroads and with Brooklyn

By JOHN W. LIEB
*Vice-President The New York Edison Company*

THE starting of the historic Pearl Street station on Sept. 4, 1882, initiated the service of The New York Edison Company, as well as central-station electric service in the world as it is thought of today. Contemporary scientists predicted the failure of the undertaking, designating it as an absolute "ignis fatuus," but it proved to be a forerunner and established the basis of the highest type of central-station supply as it is now known. In the short period since the starting of the old Pearl Street station in New York the tremendous accomplishments of The New York Edison Company and The United Electric Light & Power Company have been recorded.

The territory directly served by these companies covers Manhattan and, together with its affiliated distributing company, the Borough of the Bronx. The electrical energy required in the city of Yonkers, served through the Yonkers Electric Light & Power Company, is also provided from the generating stations of the companies, as is a part of the energy required in the Borough of Queens and in Westchester County, which are served through allied companies, the New York & Queens Electric Light & Power Company and the Westchester Lighting Company. Thus the energy generated by the allied companies serves a territory extending from the southern tip of Manhattan Island to the Putnam County line, a distance of about 50 miles, and includes Yonkers, Westchester County and the Boroughs of Manhattan, Bronx and Queens as shown on the map of the metropolitan district.

The area of the territory served directly by The New York Edison Company and The United Electric Light & Power Company is approximately 40 square miles, with about 3,000,000 inhabitants, while the corresponding figures for the entire territory referred to are 550 square miles and about 3,800,000 inhabitants.

### Five Generating Stations

The generating stations of the two companies comprise five stations of a total rated capacity of 635,000 kw., of which 405,700 kw. is 25-cycle alternating-current and 221,500 kw. is 60-cycle, with 7,800 kw. of direct-current generation. In order to care for the load of the coming winter there will be added a 35,000-kw., 25-cycle turbo-generator, making the total capacity of the stations 670,000 kw. Including the stations of the Third Avenue Railroad and the Hudson and Manhattan Railroad, which are operated by the companies under lease and are rated at 60,000 kw., there is in 1923 a total generating capacity, operated as a unit under the combined auspices, of 730,000 kw.

Waterside generating stations Nos. 1 and 2 are adjacent to each other on the East River between Thirty-eighth and Fortieth Streets. Waterside No. 1 commenced operation with large engine generator units, which have all been replaced by steam-turbine generator units, and it now has a total installation of ten units with an aggregate capacity of 174,000 kw. Two of the units are of 35,000 kw. capacity each, and all of them are 25-cycle except two small 60-cycle units aggregating 16,500 kw. The generating equipment of Waterside No. 2 comprises ten steam-turbine generator units of an aggregate capacity of 152,200 kw., of which all are 25-cycle except one 60-cycle unit of 14,000 kw. capacity. The Sherman Creek generating station of the United company, in Manhattan on the Harlem River at Two Hundred and First Street, contains eight steam-turbine generator units with an aggregate capacity of 151,000 kw., of which 40,000 kw. is 25-cycle and the remainder is 60-cycle. The Hell Gate generating station of the United company, on Long Island Sound at the foot of One Hundred and Thirty-fourth Street in the Bronx, with an ultimate capacity of 300,000 kw., has now installed two 35,000-kw., 25-cycle steam-turbine generators and two 40,000-kw., 60-cycle units. The original Duane Street generating station of 7,800 kw. capacity supplies direct current feeding into the Edison network in the business district near the southern end of Manhattan.

The Hell Gate generating station receives most of its coal from oceangoing ships and is equipped to unload such boats rapidly. Thus, during the recent extreme

shortage of coal, coal-laden boats from England went directly to the Hell Gate dock for unloading. This station is also equipped to receive coal by rail as well as by water. The other generating stations receive their coal by barge, the coal being brought to New York tidewater by rail, supplemented by the supply for the Shadyside storage yard.

The fuel supply for the generating stations is fortified by the large Shadyside coal storage yard, with a capacity of 240,000 tons, on the west bank of the Hudson River opposite Ninety-sixth Street, local storage capacity at the Hell Gate Station amounting to 60,000 tons, a total of 300,000 tons exclusive of the coal in process of utilization in the bunkers over the boilers of the several generating stations. In addition to this adequate provision for emergencies, the companies further participate in the storage facilities provided at the Consolidated Gas Company's plant at Astoria, with a capacity of 700,000 tons, located immediately opposite the Hell Gate station.

All of the generating stations are interconnected by tie cables of sufficient capacity to supply the loss in emergency of the largest unit in any station. Ties are also maintained through all substations to provide for the loss of at least one transmission cable.

The load dispatching of the entire system is supervised and directed by a system operator at the Waterside station. The system operator's room is equipped with a pilot board automatically indicating the position of all switches in all generating stations and all switches controlling high-tension feeders to substations and customers. A special telephone switchboard is installed with direct lines to all substations and generating stations and with trunks to several telephone exchanges. A Gamewell fire-alarm system is also provided for simultaneous instantaneous signaling between all substations and generating stations. All city fire alarms from the district supplied by the high-pressure pumping stations are also recorded at the system operator's room, and storm warnings are received by a "wireless detector."

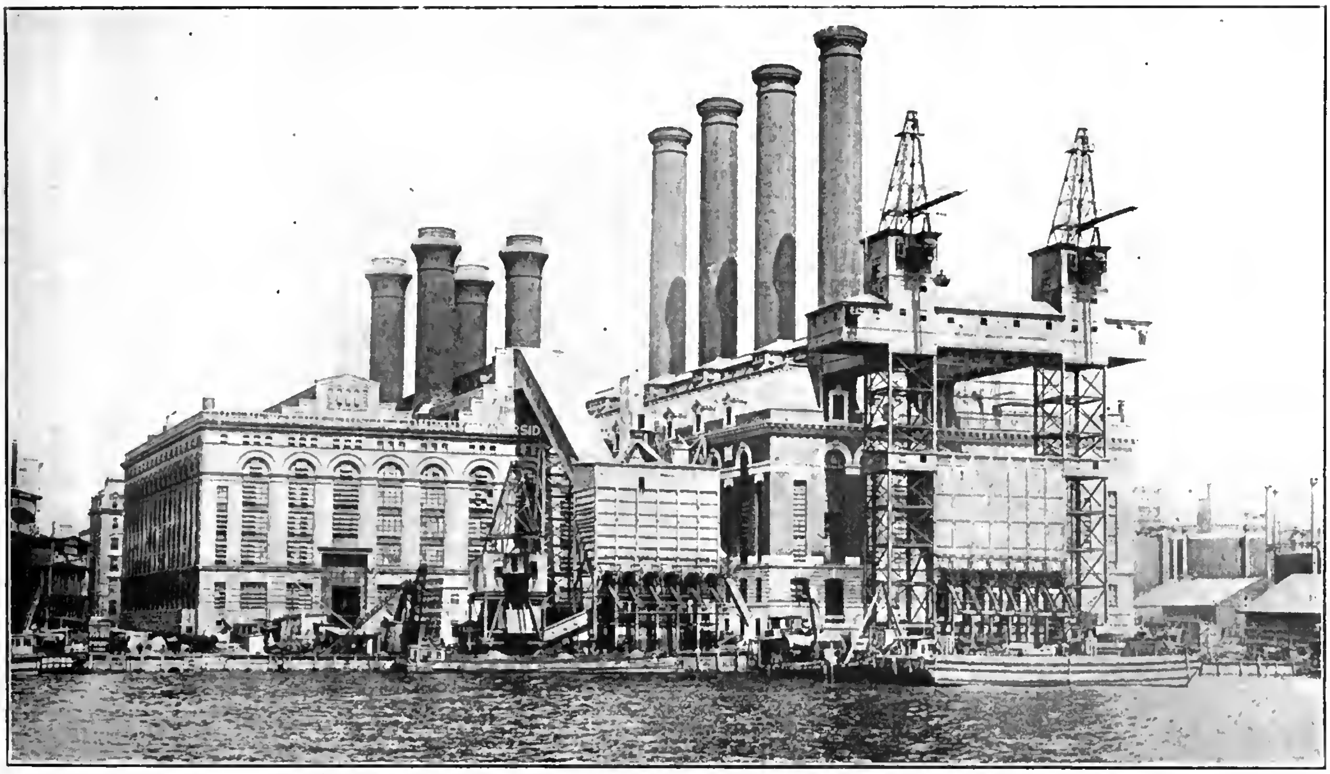
The total demand on the Edison and United generating stations in 1922 was 525,000 kw., and the total output for that year was 1,665,000,000 kw.-hr.

It is interesting to note that in Manhattan sudden thunderstorms are sometimes accompanied by inky darkness, causing the midsummer load to rise to an amount almost equal to the previous winter's maximum. Thus the spare peak capacity usually found in central stations during the summer months is not available, a condition singular to Manhattan Island.

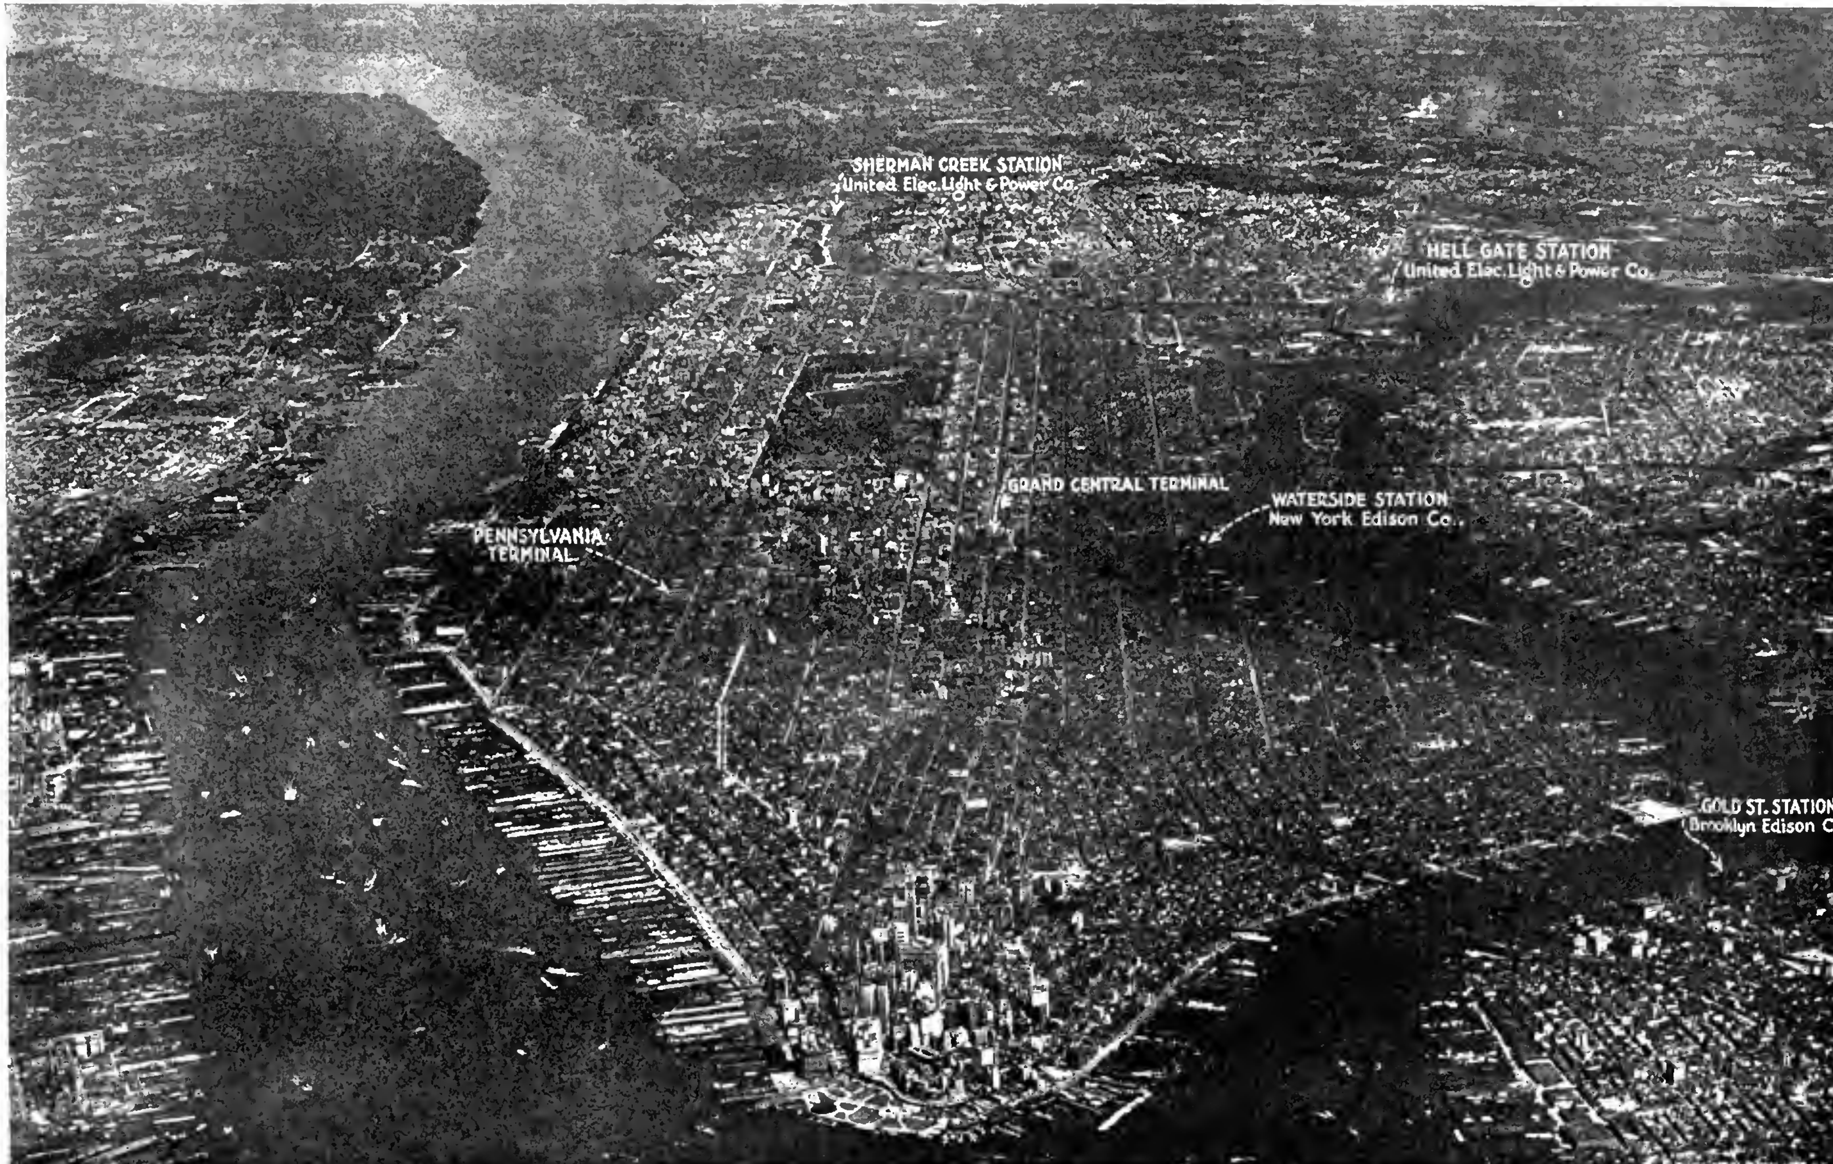
Energy is supplied to 25-cycle substations over radial feeders at 6,600 and 11,000 volts and to 60-cycle substations through parallel feeders at 7,800 and 13,200 volts. All transmission feeders operated by the Edison and United companies are carried underground. The supply to the Westchester Lighting Company is through two 45,000-volt underground feeders at 60 cycles (six single-conductor cables) from the Sherman Creek generating station to the New Rochelle substation, at which this energy is transformed to 13,200 volts for supply to other substations.

The northern end of Westchester County is also supplied from the Dunwoodie Avenue substation of the Yonkers Electric Light & Power Company via 45,000-volt overhead lines to the Elmsford substation. The New York, New Haven & Hartford Railroad Company is supplied by three-conductor, 25,000-volt underground cables at 25 cycles which tie in with the railroad's generating station at Cos Cob.

Tie connections for interchange of power are also maintained with the Interborough Rapid Transit Company at 11,000 volts, 25 cycles; with the Pennsylvania Railroad at the same voltage and frequency through the Jersey City Station of the Hudson & Manhattan Company; with the Brooklyn Rapid Transit Company at



WATERSIDE STATION OF THE NEW YORK EDISON COMPANY



©Fairchild Aerial Photo Co., New York

Aerial Photograph of New York, Showing Location of Electric Generating Stations

6,600 volts, 25 cycles, and with the Brooklyn Edison Company at the same voltage and frequency and also at 13,200 volts, 60 cycles. The last-named connection is now being changed to operate at 26,000 volts.

High-tension energy is supplied in bulk to certain large customers, such as ice manufacturing companies, mostly at 7,800 volts or 13,200 volts, 60 cycles, through single or multiple loop feeders, with automatic switches in the customers' premises. This service is in all cases stepped down to not more than 440 volts by the customers' transformers. In the case of the pumping stations for supplying high-pressure water for city fire protection the energy is fed at 6,600 volts, 25 cycles, with two direct feeders from separate generating stations and two feeders from separate substations to each pumping station, the pump motors being operated direct at the 6,600-volt feeder pressure. This service, as will be appreciated, is of a highly important character, supplying water through a separate system of mains to the fire hydrants in the business sections of the city. It may be interesting to note that a very definite penalty clause for failure to supply energy is included in the contract.

### Manhattan's Thirty-two Substations

The thirty-two substations serving the direct-current network in Manhattan have a total capacity of 380,000 kw. in 185 25-cycle synchronous converters, of which the largest units are of 4,200 kw. normal capacity. The conversion equipment is supplemented by storage batteries capable of supplying a discharge of 60,000 kw. for one hour. The output of these substations is distributed over 1,600 feeders connected to a network of 810 miles of service mains.

Part of this same territory is also served by 60-cycle low-tension distribution. This, together with the portion of Manhattan north of One Hundred and Thirty-sixth Street and the Bronx west of the Bronx River, is supplied by ten substations of a total capacity of 140,000 kva., the transformers used being mostly in sizes of 2,000 kva. and 3,000 kva. The 60-cycle distribution in Manhattan is at 3,000 volts, two-phase, three-wire, lighting being supplied across the outside legs. In the service fed from one substation this has now been changed to three-phase service and a low-voltage interconnected network has been put into service. In the Bronx the distribution is at 2,300 volts, two-phase, four-wire.

The system in Queens Borough, supplied by the six substations of the New York & Queens Electric Light & Power Company, with a total capacity of 90,000 kva., utilizes 2,300-4,000-volt, three-phase, four-wire distribution circuits, the high-tension feeders operating at 7,800 and 13,200 volts. Westchester County is served through thirteen substations of the Westchester Lighting Company, with a total capacity of 50,000 kva., the transmission voltage between substations being 13,200 and the distribution at 2,300 volts, two-phase. The city of Yonkers is supplied from the two substations of the Yonkers Electric Light & Power Company, the total capacity in step-down transformers being 15,000 kva., the transmission between stations at 13,200 volts and the distribution at 2,300/4,000 volts, six-phase, four-wire. The distribution from that portion of the Bronx east of the Bronx River is supplied from the Bronx Gas & Electric Company's substation at 2,300 volts, two-phase.

The foregoing can be considered a brief outline of the generating, transmission and substation features of the system of The New York Edison Company, The United Electric Light & Power Company and associated companies in the Bronx, Queens and Westchester Counties.

The districts other than Manhattan are largely similar to cities of the same population in the character of their load, composed of residential, business and power consumers. The load in Manhattan Island, however, an area of 21 square miles, represents the most concentrated diversified central-station load in the world, both from a standpoint of the population served (an average of 114,700 per square mile) and the density of the load itself.

As a result of the concentration of load and the restricted area the physical conditions affecting the distribution systems are peculiar. The load continues to increase year by year at a more or less uniform rate of from 12 to 15 per cent, and this means a continuing growth within a fixed area without reaching saturation.

The factors of building and population which cause the increase in central-station load carry with them also an increase in all other facilities such as transit, gas, water and steam, producing a progressive congestion of physical equipment within the fixed boundaries of the streets that makes the problem of construction of substations and installation and maintenance of distribution systems increasingly difficult because of space limitations and restrictions due to subsurface structures.

Coupled with the enormous concentration of load is the character of the load itself, which requires adequate and uninterrupted service at all times to newspapers, ticker service, telephone, telegraph and other wire communication systems, city lighting, fire service, hospitals, office buildings of great magnitude where the electric elevator service represents vertical transit facilities to innumerable tenants, and similar important service. The company-owned meters total in Manhattan Island alone approximately 350,000, to which should be added many thousands of customer-owned meters in individual buildings.

### Street Lighting System

It may be of interest to add a word relative to the carefully planned street lighting throughout the city. The companies referred to supply approximately 50,000 street lamps of the multiple and series types of the high-efficiency "type C" form of Mazda incandescent lamp. The outstanding feature of the planning of the street lighting is the zoning of the districts and the allocation of lamps from 100-cp. size for suburban districts to the twin form of post carrying two 500-watt lamps for districts comparable with Fifth Avenue, Times Square, etc.

The lamp posts are of an ornamental type designed for the particular districts both as to height and form and are of types suitable for the residential districts, the business sections and the boulevards, parks and more highly developed avenues. The wide variation in the size of the "type C" incandescent lamp from 100 cp. to 750 watts enables application of illumination intensities, and, in combination with the proper post design, provides for a standardized equipment suitable for any desired street illumination.

From this brief summary a conception may be had of the conditions under which current is generated and distributed from the generating stations and substations on Manhattan Island and in the Bronx and the territories adjacent thereto served by the distributing systems of the companies allied with the Edison-United companies and from the standpoint of generation of current operated as a unified system.

# Alternating Current in New York

## Growth of Business Has Necessitated Additions to the Hell Gate Station of the United Electric Light & Power Company—Interesting Features of New Equipment

By FRANK W. SMITH

*Vice-President and General Manager The United Electric Light & Power Company*

FROM its Hell Gate generating station and its Sherman Creek station The United Electric Light & Power Company supplies electricity both to its allied companies and to the 82,150 customers on its lines. Because of the first class of service the United company may perhaps be considered in the nature of a "superpower company." Apropos of the second, it is interesting to note that of the total 82,150 customers supplied with United service on April 30 of this year 56,277 represent those residing in the Washington Heights section—that territory in Manhattan north of One Hundred and Thirty-fifth Street, which is exclusively supplied by the United company. Electric light and power facilities were first introduced in this district on Dec. 26, 1899. The remarkable strides taken in less than a quarter of a century are apparent in the fact that nearly four-fifths of the company's business is established in this new field.

The Hell Gate station was constructed for an ultimate capacity of 300,000 kw., and at the present writing equipment to one-half of this amount has been put into operation. At the Sherman Creek station the total capacity of 150,000 kw. has been utilized for some time. During the month of April 40,000,000 kw.-hr. was generated at Hell Gate, and the maximum load was 103,500 kw. At Sherman Creek during the same month 33,500,000 kw.-hr. was generated, with a maximum load of 94,000 kw. In comparison with these figures the following data for January, 1923, may be of interest: Hell Gate, 40,700,000 kw.-hr., with a maximum load of 110,000 kw. Sherman Creek, 39,327,000 kw.-hr. with a maximum load of 103,300 kw.

### Additions to Hell Gate Station

A description of the new Hell Gate station appeared in the ELECTRICAL WORLD for April 29, 1922. In that issue the departures from conventional practice were accentuated and described in some detail.

Among the features which make Hell Gate station stand out as an unusual plant are the following: The turbine room is next to the river, with the boiler room between it and the electrical galleries; alternating-current-driven auxiliaries are used, with one or two exceptions; phase isolation of all electrical equipment has been carried out; the ashes are sluiced by hydraulic means; the station equipment has been divided into four independent groups, and heat-balance control is provided. The arrangement of condenser circulating-water intakes and discharge, the use of boilers with superheaters only six tubes above the combustion chamber, the extensive equipment of motor-operated valves, the truck-type switchboards for station service and the coal-handling facilities are also worthy of note.

Oceangoing coal boats may land directly alongside the station for unloading by means of the coal towers. In addition, a direct siding from the New York, New Haven & Hartford Railroad permits the receipt of coal by rail—a feature possessed by Hell Gate alone among the generating stations in New York. The existence of two independent routes for bringing coal to the plant is of tremendous value in view of the absolute continuity of service that must be maintained on the system. The Hell Gate site possesses a further safeguard in this respect in having an outside storage capacity of approximately 100,000 tons, which insures about four weeks' operation at the ultimate load in case all the other sources of coal supply are cut off.

When the Hell Gate generating station was constructed it was planned to add further sections of equipment as the demand would warrant. This policy has been adhered to from the start. In line with this three new sections of electrical galleries are being added this year to the four sections already installed. These three sections of electrical galleries occupy an area of, roughly, 105 ft. x 94 ft. and are seven stories high.

The same system of compartments will be employed in these sections, and the same method of installing the ducts with paper forms will also be used. As described in a previous issue of the ELECTRICAL WORLD, two of the first four sections of the electrical galleries were equipped for 25-cycle operation and two for 60-cycle. The three new sections will be equipped entirely for 60-cycle service, but two of the present 60-cycle sections will be reconnected for 25 cycles. The installation will then comprise four 25-cycle sections and three 60-cycle sections for the coming year. This reconnection does not involve any considerable expense as most of the apparatus is suitable for either frequency.

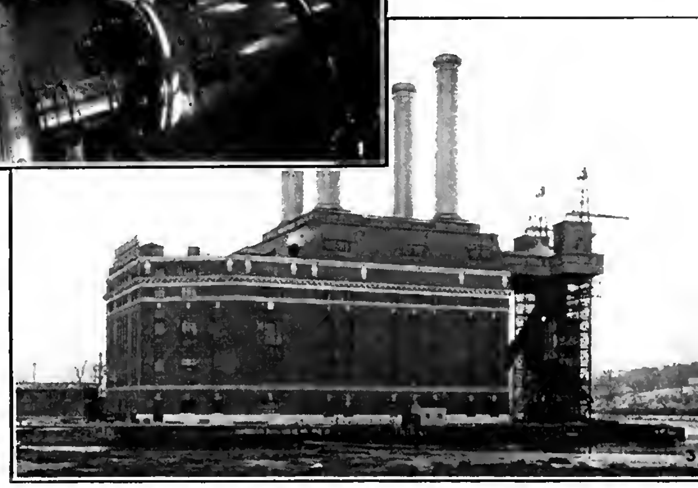
There have been purchased for the new sections ninety-nine Westinghouse circuit breakers of the same type and rupturing capacity—1,500,000 kva.—as was originally installed. These range in capacity from 3,000 amp. for the generators to 600 amp. for the feeders. The installation of this type of equipment in the present installation was an innovation, but the satisfactory service given made it advisable to continue the equipment along the same lines. In addition there have been purchased from the Metropolitan Device Corporation 120 porcelain-clad reactors of 3 per cent and 5 per cent reactance. This equipment also duplicates that installed originally.

### 50,000-Kw. Unit Purchased for 1924

For installation this year one General Electric 35,000-kw. turbine, similar in a general way to those now installed, has been bought. This turbine will exhaust into a Worthington condenser similar to that already in service. The circulating pumps, however, will be driven by two-speed motors instead of by the constant-speed motors used on all of the present circulating pumps.

A 50,000-kw. unit which is of especial interest has

been purchased from the Westinghouse Electric & Manufacturing Company for the 1924 installation. The turbine is to drive a 62,500-kva., 60-cycle, three-phase, 13,200-volt generator and will operate at 1,200 r.p.m. It is a single-cylinder unit, and in addition to the main generator it will be equipped with an auxiliary power generator of 2,000 kw., 2,500 kva., for auxiliary service at 60 cycles, three-phase, 2,400 volts. This auxiliary generator will be directly coupled to the main generator shaft, and a directly connected exciter will be on the end of the auxiliary generator shaft. The unit will have its best point of economy at 35,000 kw. and will have a peak-load capacity of 56,250 kw. A fairly flat performance curve between loads of 25,000 kw. and 56,250 kw. is guaranteed. The length of the entire unit with auxiliary generator and directly connected exciter will be approximately 77 ft. by about 22 ft. in width. This size permits the unit to fit nicely into the same space as is occupied by each of the present units. This unit represents the first 50,000-kw. single-cylinder unit which the Westinghouse company has contracted to make. Its design is of the impulse reaction type, consisting of one double Curtis wheel followed by the standard reaction intermediate blading and low-pressure blading of the so-called "Bauman" type, which permits the turbine to exhaust through one single-exhaust opening, there being three multiple passages through the Bauman blading to this single exhaust. It will be arranged for feed-water-heating purposes, the present plan being to provide for feed-water heating by four stage bleeding of the turbine, using the auxiliary generator to provide the necessary power incidental to the operation of the unit. It might also be noted that this is the first unit of this capacity to be equipped with a small generator on the main shaft for auxiliary power purposes. The present installation at Hell Gate consists of twelve 1,890-hp. Springfield boilers with no economizers but equipped with superheaters above the lower six rows of tubes. Under each boiler there are two fourteen-retort, seventeen-tuyère Taylor stokers discharging into a central ash pit. Although this installation is working satisfactorily, it was thought that further economies could be accomplished by a modification of it. Three new boilers have been purchased of the same general design but of 1,550 hp. each. Instead of being twenty tubes high they will be sixteen tubes high, with four rows instead of six below the drop leg. In addition to superheaters these boilers will be equipped with economizers. These are to be furnished by the Power Specialty Company. They are of the one-pass, counter-current design with elements 18 ft. long over rings and will have 13,824 sq.ft. of external heating surface. Each unit will be sixteen elements wide and fourteen rows high. The superheaters, instead of being placed in the original position, will be installed on the top of the first pass. Instead of a double stoker there will be a single fourteen-retort, thirty-three-tuyère Taylor stoker. These changes, of course, necessitate a different baffling arrangement.



HELL GATE AND SHERMAN CREEK STATIONS, SHOWING INTERIOR OF SHERMAN CREEK STATION

The same method of disposing of ashes by a sluicing system will be maintained. On account of these boilers being fed from only one side it will not be necessary to purchase another coal lorry at this time.

An equipment of forced-draft and induced-draft fans similar to that of the original installation will be installed driven by B. T. S. General Electric motors. These motors have operated satisfactorily, and their purchase for this installation is economically sound.

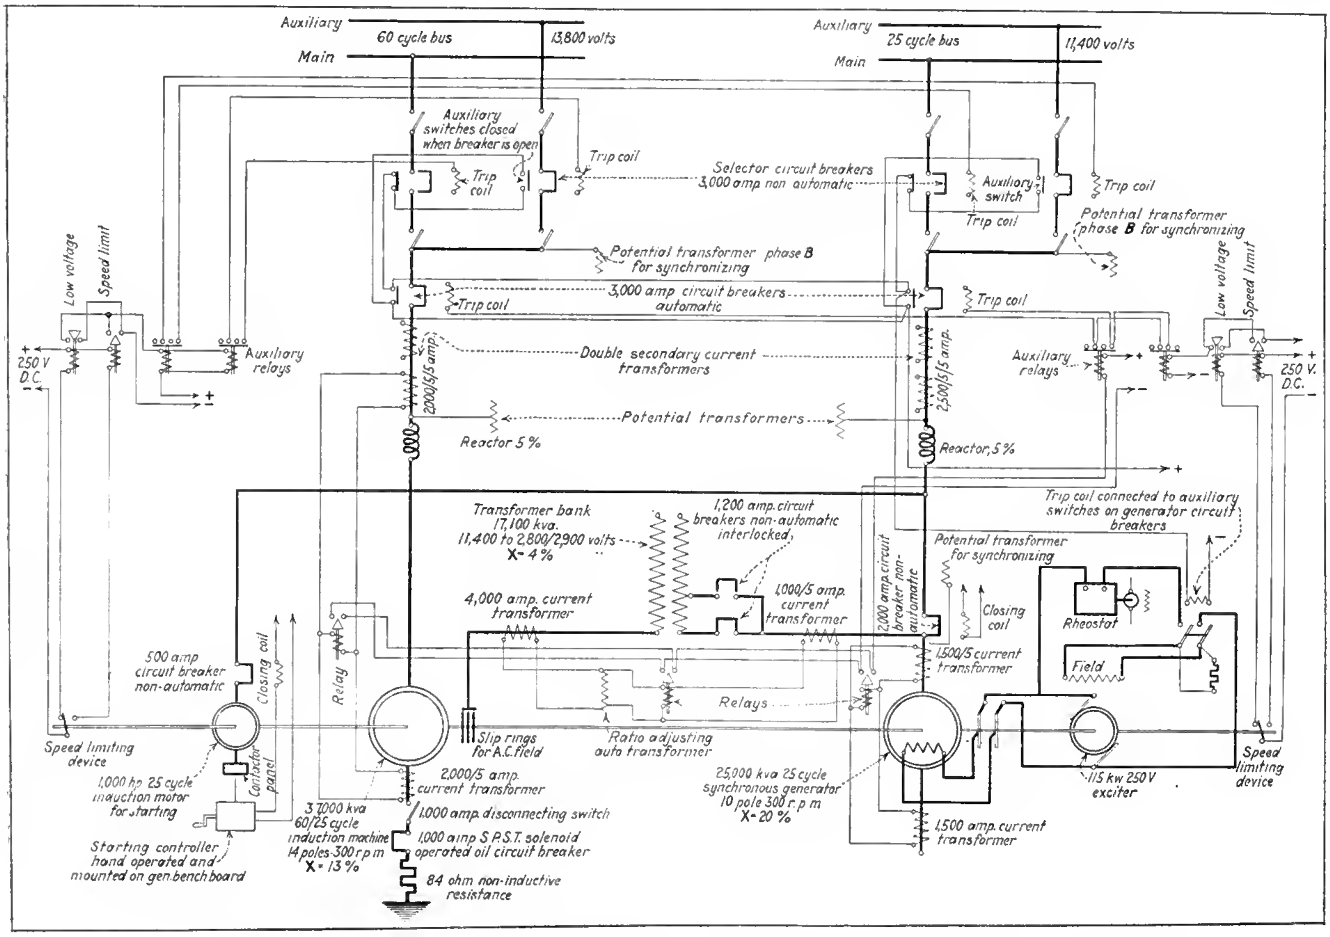
The present auxiliary power for the Hell Gate station is obtained from two banks of transformers fed from the main 60-cycle, 13,200-volt bus and stepping down to 2,300 volts, and from two 2,500-kva. turbo-generators generating at 2,300 volts. For the present year this will be sufficient. A further extension, however, is necessary to the truck switch installation. New switches have been purchased from the General Electric Company in sizes of 400, 1,200 and 2,000 amp.

An interesting addition to Hell Gate which is expected to be in operation during the coming fall is the installation of five 12,000-kva. oil-cooled outdoor-type transformers. These are the largest type of self-cooled transformers made. With their oil they weigh 42½ tons each, but in spite of this weight they will be shipped filled with oil to eliminate the drying out of coils after being received. They will be used to supply service to allied companies and will be installed at the extreme south end of the part of the property devoted to electrical galleries. They are delta-connected on the low-voltage side and star on the high and step up from 13,800 volts to 28,980 volts. They will have additional taps for approximate voltages of 27,600, 26,100, 24,700 and 23,000 for operation at full kilovolt-ampere capacity. They are of the core type with interleaved disk windings and will be equipped with conservators, ratio adjusters for the taps and temperature-indicating coils.

There will be installed for operation this year a 35,000-kw. induction synchronous-type frequency converter to be used for tying together the 25-cycle and the 60-cycle systems. Units of this type in large sizes have not previously been built, and its operation is looked forward to with interest. The set is to be furnished by the General Electric Company. It operates at 300 r.p.m. and consists of a 37,000-kva. wound-rotor induction motor having fourteen poles, a 13,800-volt, 60-cycle stator, and a 2,850-volt rotor wound for 25 cycles directly connected to a synchronous 25,000-kva., 25-cycle generator operating at 11,400 volts. On the same shaft are installed a six-pole, 115-kw., 250-volt exciter and a 1,600-hp., 11,400-volt, three-phase, 25-cycle starting motor. Between the slip rings of the main induction machine and the high-voltage 25-cycle bus is a 25-cycle, 17,100-kva. transformer stepping down from 11,400 volts to 2,850/2,950 volts.

The synchronous machine is a ten-pole generator having a synchronous speed of 300 r.p.m. The 60/25-cycle induction unit is wound for fourteen poles. At 60 cycles it would have a synchronous speed of 514 r.p.m. By holding the rotor speed down to 300 r.p.m. with the synchronous generator a slip of 214 r.p.m. is obtained in the induction machine, which gives 25 cycles at the collector rings of the rotor. The stator of the induction machine is connected to the 60-cycle line, and the rotor of the induction machine and the stator of the synchronous machine are both connected to the 25-cycle line. A transformer is required for connecting between the collector rings of the induction machine and the 25-cycle bus, because it is not practicable to build a high-voltage rotor for this machine, and this transformer also gives an opportunity for ratio adjustment for the control of current flow through the induction unit.

The induction machine will be excited from the 25-cycle side, the synchronous generator supplying this



LAYOUT FOR OPERATING A 35,000-KW. SYNCHRONOUS FREQUENCY CONVERTER USED TO TIE TOGETHER THE 25 AND 60 CYCLE SYSTEMS

excitation, so that the power factor on both the 25-cycle and the 60-cycle side of the set will be approximately unity, with full load on the set and power flowing in either direction. In order to provide this exciting kva. for the induction machine the synchronous generator is designed for 85 per cent power factor lagging load as a generator.

The induction machine furnishes an electromagnetic tie between the 25-cycle and the 60-cycle systems, similar to a transformer tie between the two parts of a system of one frequency. In other words, this machine forms a voltage tie between the systems in addition to being a power and frequency tie, and any variation or disturbance of voltage on one system will be transmitted to the other through this tie in a manner similar to that obtained through a transformer. The effectiveness of this voltage tie is dependent upon the reactance of the circuit through the induction machine between the two systems.

The flow of wattless current between the two systems may be controlled by adjusting the transformer ratio or by changing the bus voltage on either the 25-cycle or the 60-cycle system. For general operation these ratios will be adjusted to give unity power factor.

# Phenomenal Growth in Brooklyn

## Edison Company Erecting New Superpower Station, Changing Its Distribution System and Expanding Its Various Departments to Take Care of the Ever-Growing Demands

By M. S. SLOAN
*President Brooklyn Edison Company, Inc.*

THE progress of the Brooklyn Edison Company, Inc., has been rapid and consistent since the opening of the European War, and since the end of the war a large and steady average increase in business each year has been maintained. In 1922 this increasing business had reached a point where the company was justified in adopting a plan of expansion for the next five to ten years, conservatively predicated on past requirements, of a far greater scope than any previously contemplated in its history. A brief synopsis of this growth and the plan of expansion now in progress of execution is presented here.

The growth of the company's business is compactly shown in the tables, which cover the increases in customers, output, capacity, demand, gross revenue, domestic and industrial development.

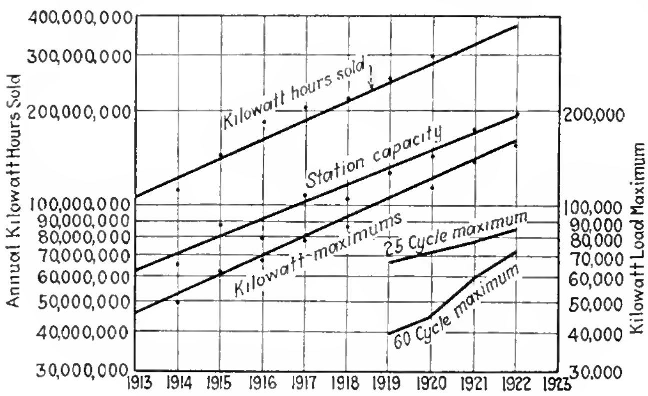
The diagram of output, maximum demand and capacity exhibited illustrates very clearly the basis of growth on which the present expansion is planned. The Brooklyn Edison Company, Inc., now has two generating stations in operation besides an interconnection with the plant of The United Electric Light & Power Company at Hell Gate in the Bronx. The largest of the two stations is on the East River at Gold Street; it has a capacity of 125,000 kw. of 25-cycle generators. The second station is at Sixty-sixth Street and New York Bay, having 65,000 kw. generating capacity at $62\frac{1}{2}$ cycles. To meet the future requirements of capacity and economy, to standardize and simplify its type of service in phase and frequency, and further to decrease its cost of distribution and increase its efficiency, all tending to improve and lower its cost of general service, the company has financed and started a remarkably large and comprehensive program of construction and improvement, which when completed about the end of 1924 will have cost $23,000,000.

The basis of this development is the design and construction of what will be when completed the largest steam generating station in the world, at the foot of Hudson Avenue, Brooklyn, adjacent to the Brooklyn Navy Yard. This plant will be of 400,000 kw. to 500,000 kw. capacity, consisting of eight turbo-gen-

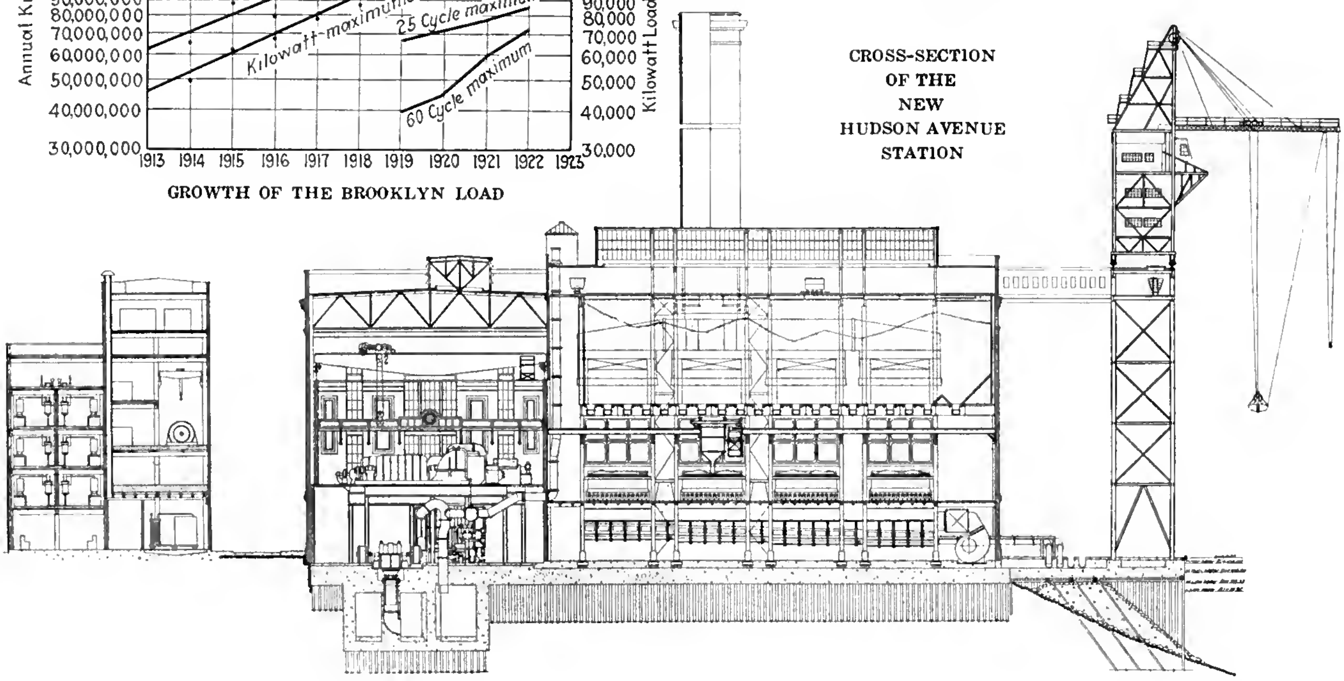
erators, three of which have been ordered. Each one of them will require a surface condenser of 70,000 sq.ft. cooling surface, supplied by two circulating pumps of 50,000 gal. each, or 100,000 gal. per minute total.

The station will be divided into four groups of two turbines each, each group being designed to be operated as a unit, the two turbines being served by eight boilers, each of 19,650 sq.ft. of heating surface, of which seven are required for normal operation of two units at maximum load, the eighth boiler being a spare.

The station is laid out on the most economical basis,



GROWTH OF THE BROOKLYN LOAD



CROSS-SECTION OF THE NEW HUDSON AVENUE STATION

the boiler room being adjacent to the waterfront, the turbine room next, and across a street the switch house, so that the least distance is required for handling coal and the most economical arrangement insured for transmitting the electric current from the generators to the switch house and thence to the transmission circuits.

The coal will be received in barges on the waterfront and hoisted by means of traveling towers on a coal trestle 112 ft. above the wharf, where it will be crushed and delivered to electric coal cars, which will be operated automatically and delivered to the bunkers over the boilers. From the bunkers the coal will be delivered by weighing lorries to hoppers of the individual stokers.

The bunkers will have a storage capacity of approximately 24,000 tons, which is six days' supply when full, based on normal steaming rate and the most economical load on the turbines. The ashes will be handled by means of hydraulic sluiceways under the ash pits of the boilers which lead to pipes under the surface of the wharf and thence to a pit on the dock, from which they will be dredged by locomotive crane into the ash scows and towed away to sea.

Steam will be received at the throttle of the turbo-generators at 265 lb. pressure, 200 deg. superheat. The electric current will be generated at 13,800 volts, stepped up to 27,600 volts in auto-transformers in the switch house and at this voltage transmitted to the 60-cycle substations of the company.

The turbo-generators have a guaranteed water rate of approximately 10 lb. per kilowatt-hour under the above conditions. It is confidently expected that the efficiency of this station will be approximately as follows:

| | 100,000 Kw., Full Load | 75,000 Kw., Three-quarters Load | 50,000 Kw Half Load |
|---|---|---|---|
| B.t.u. per kilowatt-hour........... | 17,380 | 16,760 | 18,000 |
| Total thermal efficiency, per cent... | 19.65 | 20.39 | 18.97 |
| Lb. coal per kilowatt-hour......... | 1.34 | 1.29 | 1.39 |
| Lb. steam per kilowatt-hour....... | 12.97 | 12.42 | 13.19 |

It will be noted from the foregoing that changes in the distribution system are also in progress. Originally the generation of energy by the Brooklyn Edison Company was two-phase at a frequency of 25 cycles. In 1912 about one-quarter of the energy was being distributed by alternating current, part directly at 25 cycles to large customers, and the rest at two-phase, 62½-cycle energy by means of a limited capacity in frequency changers. As the requirements and the refinements of the modern utilization of electricity have developed they have shown the desirability of three-phase and 60 cycles as the general characteristics of use, and in consequence, following the actual trend of the company's experience, an elaborate program has been adopted of changing to this phase arrangement and frequency. This program also includes a large extension of the alternating transmission system at much higher voltage than at present, for economic reasons as well as for those of physical limitations. It has proved desirable as well to change over certain portions of the low-tension direct-current distribution to alternating-current.

These changes are soundly predicated on the experience of the last ten years, during which the alternating distribution of energy increased from 25 to 45 per cent of the whole and during which the frequency-changer capacity increased from 18,500 kva. to 28,500 kva. of 62½ cycles, while 114,500 kva. of 62½-cycle substation transformers were also added.

Based broadly on these proved conditions and safely and conveniently to distribute through the streets of Brooklyn the greatly increased supply of energy from the new Hudson Avenue station, it has been necessary to increase the transmission voltage from 13,200 to 27,600, and the company is this year installing 80 miles of 350,000-circ.mil, 33,000-volt cable as an addition to its present 490 miles of transmission. The company's transmission cable in the past has always been conservatively rated, and studies now under way indicate that an appreciable portion of the existing cable installed for operation at 13,200 volts may, by rebuilding the joints, be safely operated at the new transmission voltage.

To utilize the output of Hudson Avenue station and to render available the higher transmission voltage, it has been necessary to purchase eighteen 10,000-kva. substation transformers, which will be installed during 1923. These transformers are of the oil-insulated, self-cooled type, as contrasted with the company's previous practice of using air-blast transformers of 5,500 kva. rating.

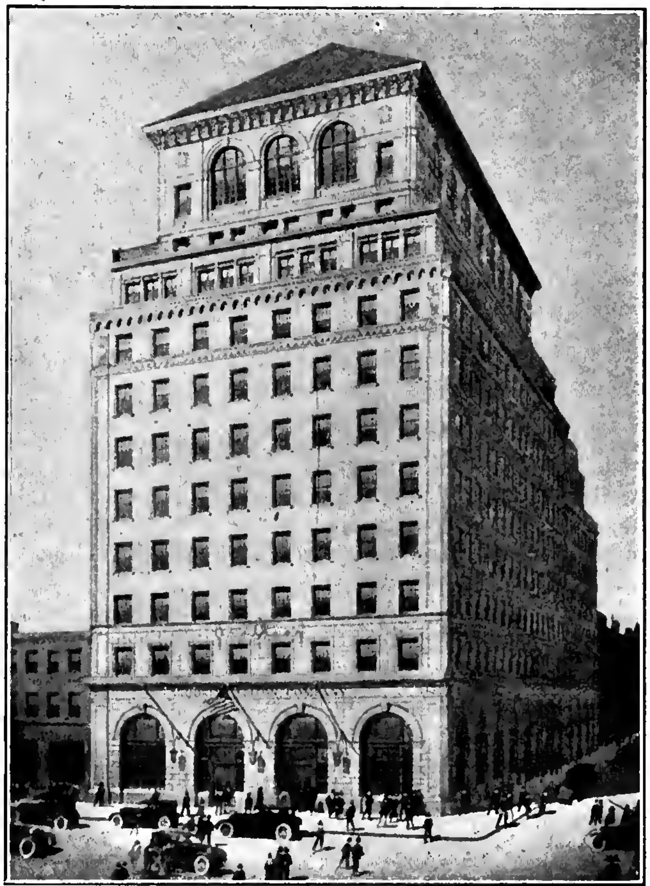
The rapid rate of growth of the company has now warranted a decision to change the distribution system from two-phase, 2,400 volts, to the almost universal standard three-phase, four-wire, 2,400-volt system, and accordingly two new substations now under construction are being developed as three-phase substations. Other substations in the process of reconstruction are being changed to three-phase, and during 1924 new substations and reconstructed old ones will be similarly changed to three-phase.

The relatively greater growth of the alternating-current territory has warranted the change in frequency from 62½ cycles to the standard 60 cycles. Both the change in frequency and the change in the number of phases will ultimately displace the present frequency changers from service, and the company is therefore installing this year a new 35,000-kva. frequency changer to interconnect the 25-cycle and 60-cycle systems. Provision has been made for the installation of a second such unit during 1924 or 1925 if occasion necessitates.

The pure economics of distribution, street congestion and the difficulty of obtaining adequate locations for direct-current substations have led to a policy of taking expansions within the direct-current district on the 60-cycle alternating-current service, and to this end a three-phase skeleton distribution network is being built throughout the direct-current territory. New business in the direct-current territory is now being taken on as alternating current, and during the year approximately 10,000 kva. of existing direct-current load will be transferred to the 60-cycle system. It should be noted that this change of direct-current to alternating-current customers is not being confined to the fringe of the substation territory but permeates the entire direct-current district. Only such customers are being changed as show a minimum cost of change-over, and the change-over, if extended in the future, will follow this general program. It is expected that some load on the premises of individual customers will remain on direct-current service for a number of years, even though the major load of the customer be transferred to alternating current.

The design, construction and extension program of 1923 is an extensive and arduous one and represents not so much fundamental change as an additional step in the maturing growth of the company. It has been the policy of the company to retain its existing standards and methods until modification should be clearly advisable and warranted and then to change in such manner as to give reasonable assurance of being in the line of development for some years to come. It is the expectation that the program for 1923 will give a large measure of flexibility and ease in making extensions and additions during the immediately succeeding years and that these extensions may be along lines standard not only with the Brooklyn Edison Company but in the industry as a whole.

In order to effect the many changes in the distribution system required in the program just described, marked developments have taken place in the application of mechanical appliances using air power for constructing services underground and in the use of trenching machines for the quick construction of duct excavations and the speedy repair of a street. All of these methods have shown not only a decreased unit cost but a decreased time of installation and better and quicker service.



NEW OFFICE BUILDING OF THE BROOKLYN EDISON COMPANY TO HOUSE ALL DEPARTMENTS

This growth of the company and the expansion of its various departments to take care of this growth have rendered it necessary during the past few years to rent considerable space and to establish many of its offices outside the present main office building. To remedy this condition the construction of a general office building has been authorized, and this is now in process of erection at the corner of Willoughby and Pearl Streets.

This building will be twelve stories in height, giving approximately 150,000 sq.ft. of available area for office purposes, and will be ready for occupancy in the early fall of this year. At that time all the departments will be brought together under one roof with the exception of certain of those concerned with construction, stores and distribution functions, for which it is planned to

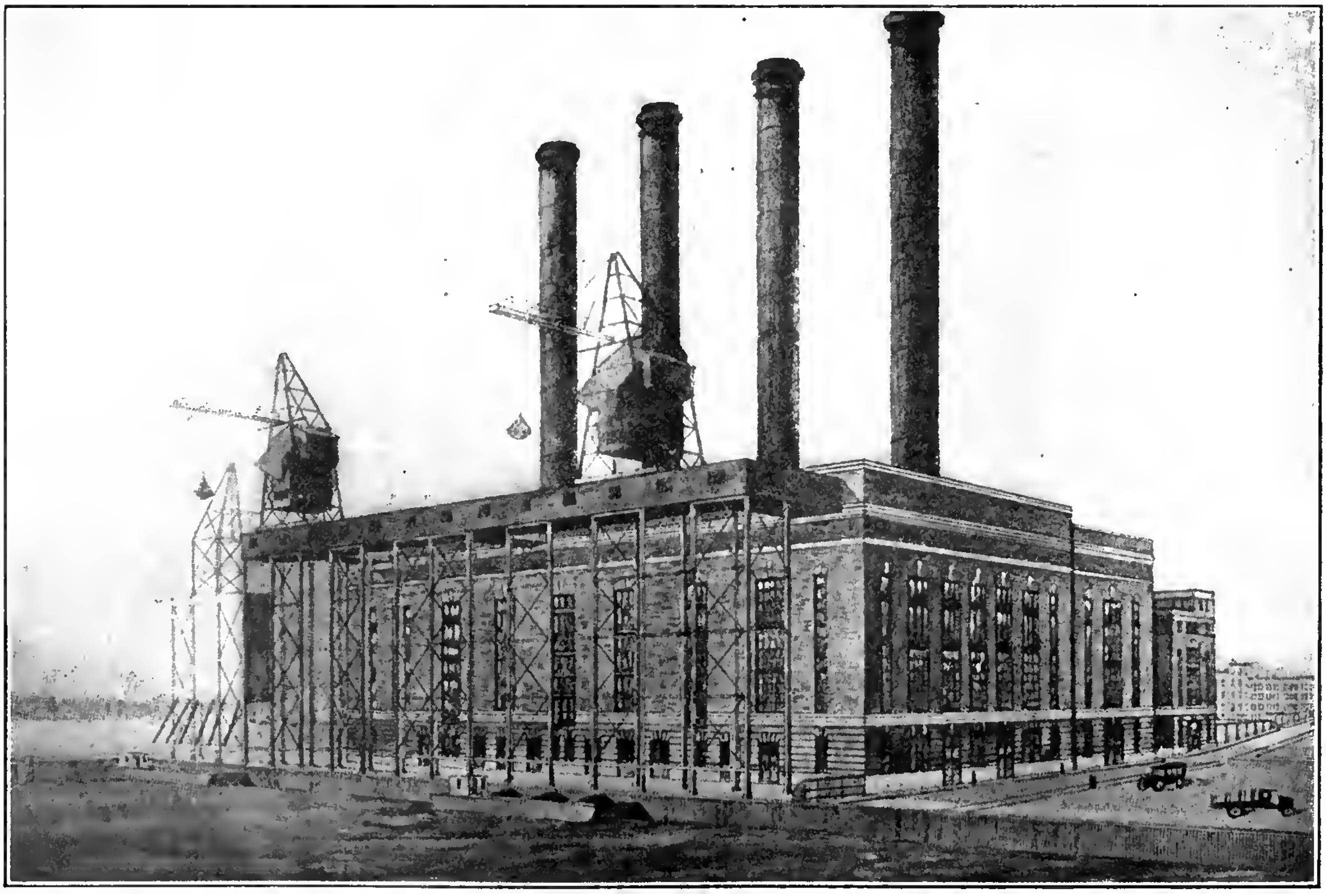
* Without Hudson Avenue. † Decrease.

erect a separate general service building at a convenient point in the near future. As the future growth of the company warrants, the general office building will be extended along Pearl Street as required.

Fuel oil will be used for generating the steam for heating the building. About 225,000 gal. of this oil will be used per year, and facilities for the storage of 35,000 gal. have been provided.

With all this increased and increasing business a strong and well-organized development is in operation for the continuous training and advantage of the company's personnel. These forces have increased from about two thousand in 1918 to nearly four thousand five hundred in 1923. The importance of surrounding this large number of individuals with proper conditions and opportunities is fully recognized, and the work is being carefully cultivated.

Within the past year a greatly improved educational training course has been established which has quadrupled the voluntary attendance as compared with previous years. This course, an employment division and a medical division are all in charge of the personnel bureau, which concerns itself entirely with the affairs of the employees in the company and their well-being. A medical examination is now required of all new employees, and free medical advice and regimen is open to all in the company. The employee and the job are studied with reference to each other, as well as the reward for excellence in the work, and an improved condition is beginning to show in the reduction of turnover. A self-governing club of the employees has been formed and is being developed by themselves with annual financial support from the company equal to what they raise by their own dues.

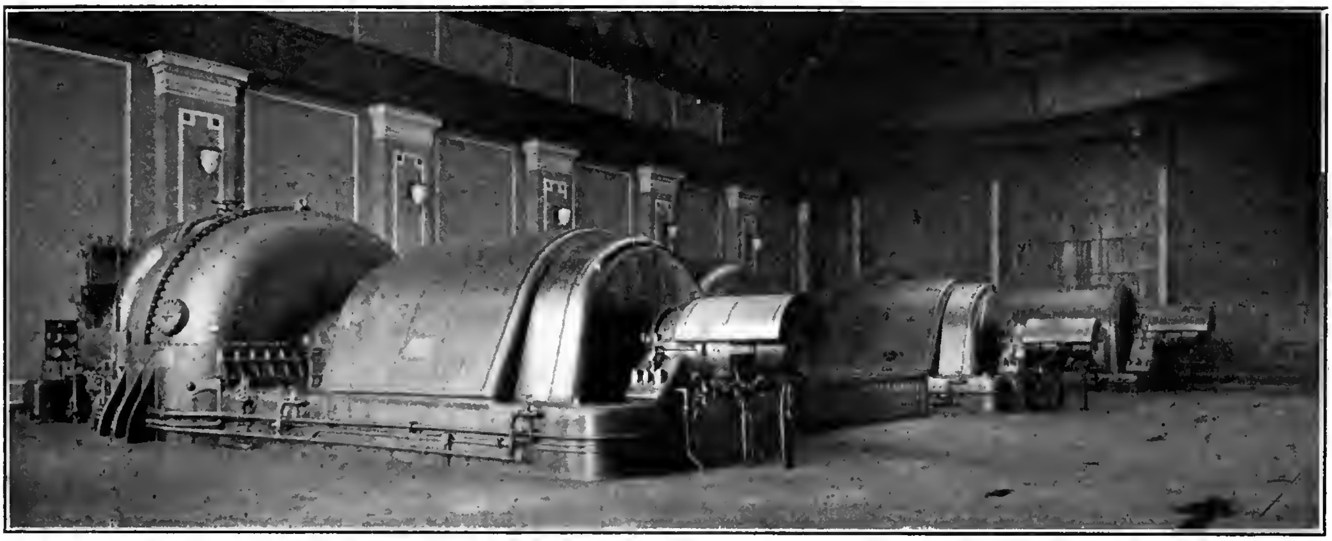


NEW HUDSON AVENUE GENERATING STATION AS IT WILL APPEAR WHEN COMPLETED

# Diversified Service in New Jersey

## Features of the Public Service Electric Company's System, Which Supplies Electricity to 202 Municipalities and Reaches the Large Industrial Centers Located Between New York and Philadelphia

By FARLEY OSGOOD
*Vice-President and General Manager of the Public Service Electric Company*



ESSEX STATION OF THE PUBLIC SERVICE ELECTRIC COMPANY

THE distinctive features that mark the operations of the Public Service Electric Company are, first, the wide extent of the territory served; second, the diversified characteristics of the communities within that territory, and, third, their rapid and continuing growth, both in population and industrially.

The area in which the company operates extends entirely across New Jersey, from the New York State line on the north to a point below Camden on the south and from the Hudson River and the waters adjoining New York Bay on the east to the Delaware River on the west. It embraces approximately 3,500 square miles, and electric service is supplied in twelve of the twenty-one counties of the state. In these counties live five out of every six of the state's inhabitants, while more than 90 per cent of the state's industrial activities are carried on therein. Probably no other electric utility in the nation serves so large a portion of the territory or of the population of the state in which it operates.

Two hundred and two different muncipalities, ranging in size from Newark, with more than 425,000 people, to communities of a few hundred, and including five cities with more than 100,000, five others with more than 50,000, ten others with more than 25,000, and sixteen others with more than 10,000, are supplied with light and power.

In their characteristics these communities are widely different. They range from great manufacturing centers, such as Newark, Jersey City, Paterson, Trenton, Perth Amboy and Camden, to purely residential towns of many classes, like Montclair, the Oranges and the hundreds of attractive suburbs in Bergen, Hudson, Essex and Union Counties in the northern section and in Burlington, Camden and Gloucester Counties to the south.

The social and industrial quality of the territory is to a large extent molded by its proximity to the great metropolitan cities of New York and Philadelphia. Sixty-six per cent of the total population served by Public Service live within 20 miles of the New York City Hall. Another 9 per cent live within 20 miles of the Philadelphia City Hall. Much of Public Service territory is within easier reach of the business center of New York than are many parts of New York itself.

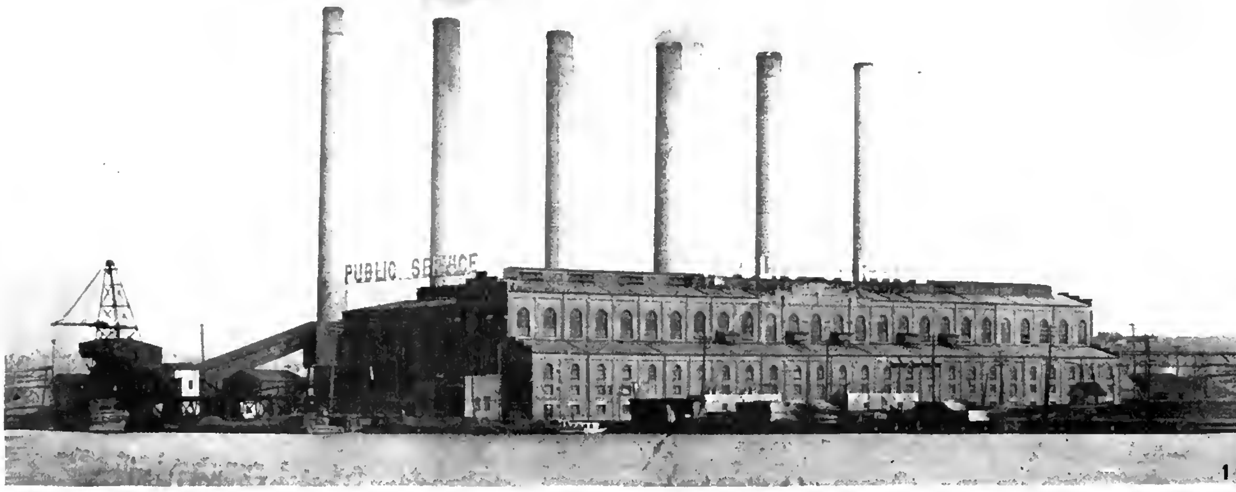
Nearly 75 per cent of the total population embraced in the twelve New Jersey counties served by the Public Service Electric Company live in six counties adjacent to New York City, although the combined area of the six is but 26 per cent of the total area served.

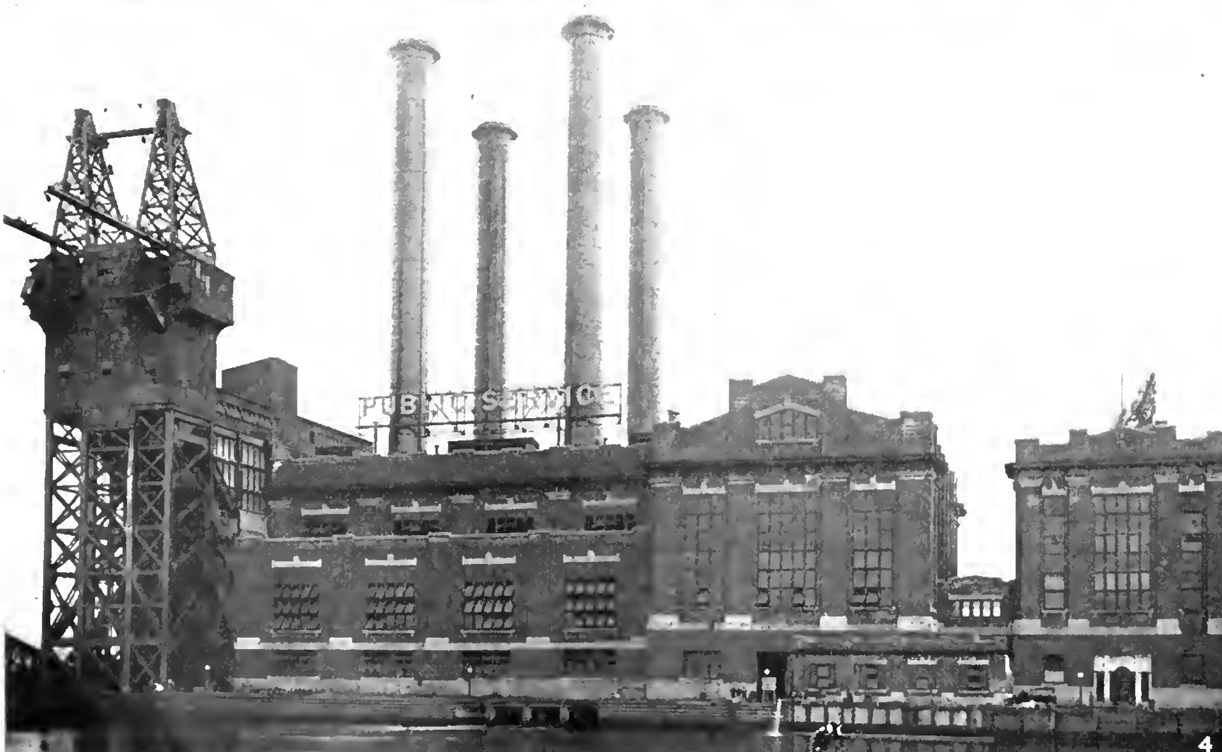
There is, then, in the northern part of the section of the state served by the company a territory about 20 miles in width, extending eastwardly from the banks of the Hudson and adjoining waters, with a high density of population; a territory extending 10 or 12 miles eastwardly from the Delaware with a lesser but still high density of population, and between them a territory of comparatively low density, and there is at the same time a concentration of industrial activities in these areas of dense population.

### ASTONISHING GROWTH OF POPULATION

The growth of all this community has been, and still is, remarkable. For the last twenty years there has been an accretion of population in the twelve counties served by the Public Service company of nearly 60,000 a year, and during this period the rate of population increase has been greater than that of New York City and much greater than that of Philadelphia.

## Marion and Essex Stations and Typical Branch Office and Substation





There has been an equally astonishing growth in manufacture. From the standpoint of the central-station man, this may best be expressed in terms of primary horsepower used in industry. The United States industrial census shows that between 1904 and 1919—the latest census was taken in the latter year—there was for New Jersey an increase of 87 per cent in the horsepower of industrial prime movers, and for the electric generators included in this total an increase of 297 per cent.

This increase came in very large part from extension in the sale of electric station energy, since we find from the census figures that while electric horsepower generated by the user increased 180 per cent in the ten years, that purchased by the user increased 852 per cent, or at the ratio of more than four to one.

The picture of the industrial and population conditions which is presented in the foregoing paragraphs is essential to an understanding of the operations of the company itself.

### Nearly a Billion Kilowatt-Hours a Year

In 1922 the company generated, to meet the light and power requirements, including those of the Public Service Railway Company, which operates a system embracing nearly 900 miles of track and which carried in 1922 some 410,000,000 passengers, 939,413,040 kw.-hr., with a load factor of approximately 44 per cent.

This total of nearly a billion kilowatt-hours was produced in fourteen generating stations. The conditions existing in the territory which has already been described indicate, in general, the distribution of load, and the general arrangement of both generation and distribution systems follows conditions of load.

The northern and central sections are very completely tied together, and energy generated in any of the stations in these sections can be distributed throughout the entire area. The southern section, extending from Princeton, near Trenton, to below Camden, is operated independently.

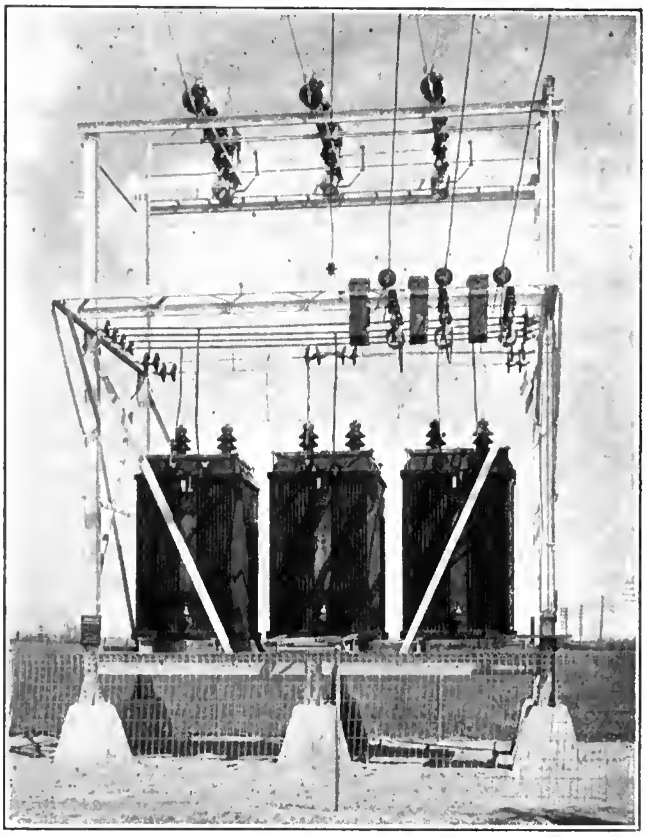
The total generating capacity of the fourteen stations is 290,900 kva., of which Essex station can furnish 85,000, Marion 90,500, Perth Amboy 22,500, and Burlington 37,500. Essex, Marion and Perth Amboy stations are in the northern and central sections. In addition, there are in this section stations of much less capacity and older design at Paterson, Secaucus, Edgewater, Hoboken, Crawford, Plainsboro, Red Bank and Newark.

The Burlington station is in the southern section and is reinforced by smaller stations at Trenton and Camden. To provide a further supply of energy when necessary, a tie with the lines of the Philadelphia Electric Company has recently been made at Camden.

The Essex station is the most modern of those operated by the company, and many of its engineering features are of interest. It is located at Point-No-Point on the Passaic River, about 2½ miles from the center of Newark, and contains at the present time one 35,000-kva. and two 25,000-kva. units, all operating at 13,200 volts, 60-cycle, three-phase.

The Passaic River at the point where this station is situated is of sufficient depth to permit coal and other material to be received by water. In addition, a spur from the Central Railroad of New Jersey provides for receipt of coal and supplies by rail. Coal received by water is handled by means of two towers erected on docks in front of the plant and capable of handling from barges 200 tons of coal per hour. Coal received by rail is handled by a system of horizontal and inclined belts and a skip hoist with a capacity of 90 tons an hour. Coal from both barges and cars is carried to bunkers at the top of the building adjacent to the boiler house. A bunker, of a capacity varying from 1,700 tons to 2,400 tons, is provided for each eight boilers. Each has a bottom dump, and coal is carried from bunker to boiler in weighing lorry cranes.

There are at present sixteen 1,370-hp. boilers, operating under forced and induced draft and equipped with modern underfeed stokers. Twelve of the sixteen are equipped with economizers. The entire switching equipment is of the remote-control type and with the bus layout is flexible enough to prevent interruptions to service as the result of switch or bus failures. An electrically operated load dispatcher's board indicates diagrammatically the exact load conditions in the system network of which Essex is a part and is of great value to the load dispatchers under the conditions of complicated and frequent operating changes that prevail.

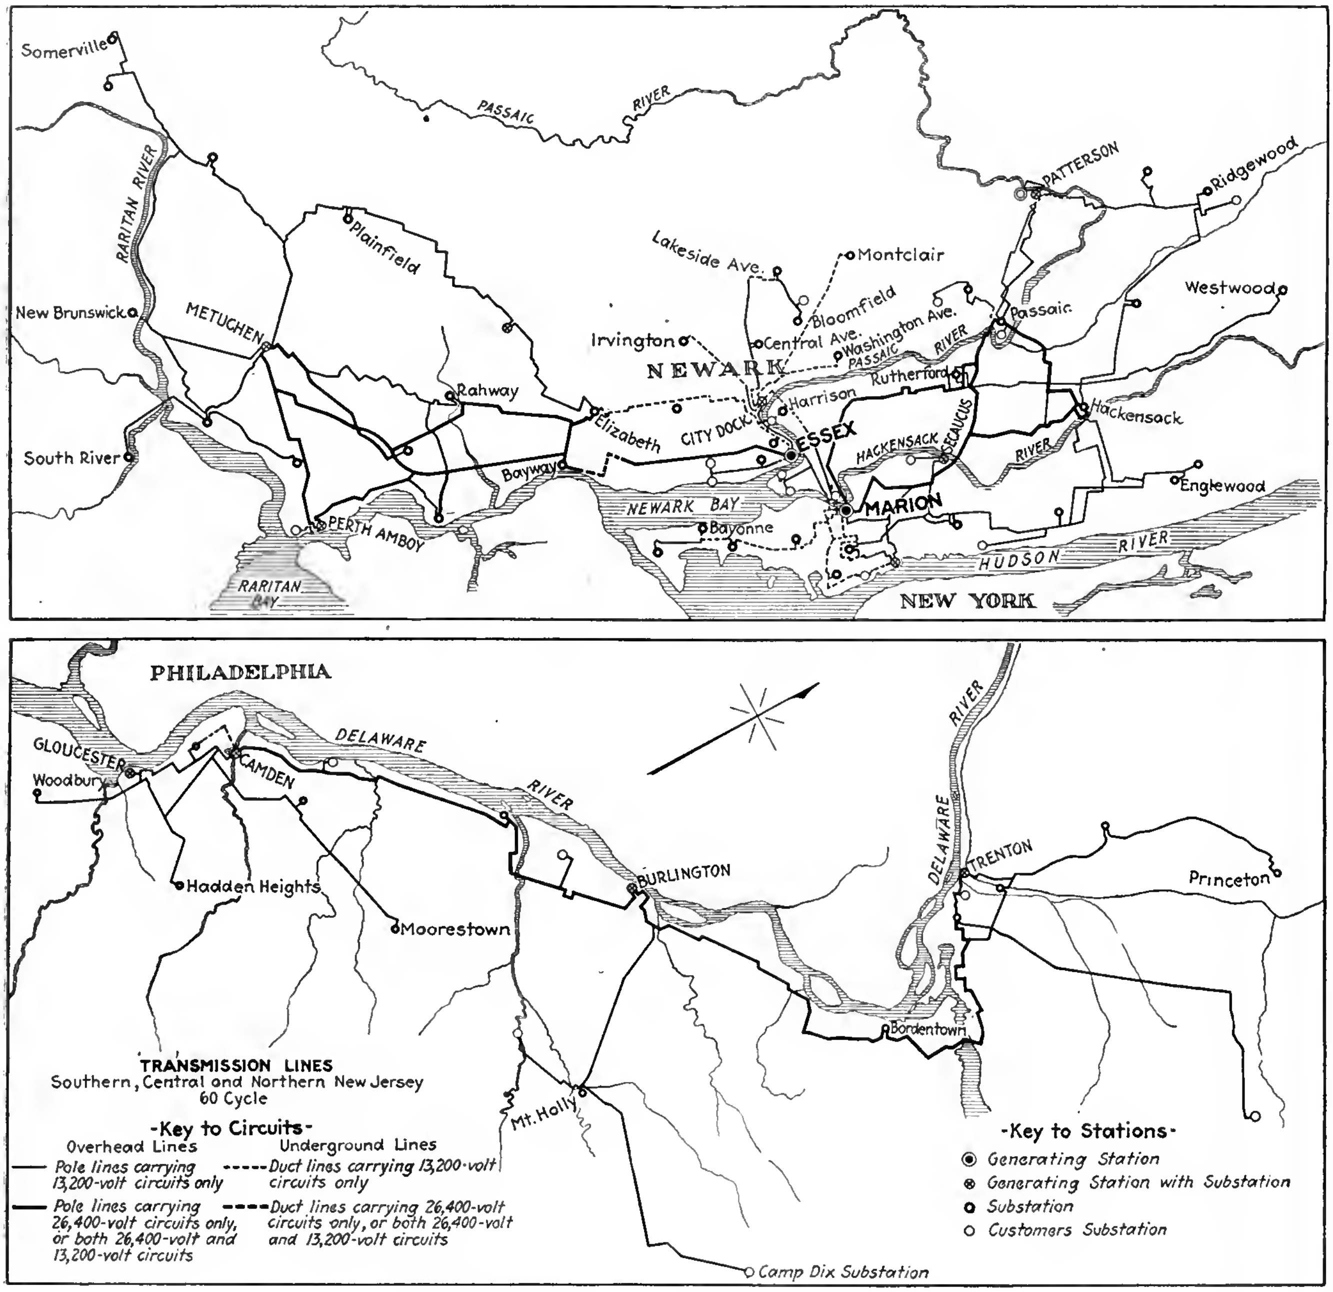


OUTDOOR SUBSTATION PUBLIC SERVICE ELECTRIC COMPANY

The architectural design of this station, both interior and exterior, is pleasing, the turbine room being a welcome departure from usual engine-room conditions.

Transmission from Essex station is, for near-by substations and plants of large consumers, at 13,200 volts. To more remote points it is, in order to cut down line losses, at 26,400 volts.

Extensions and improvements at the Essex station now under way will increase its capacity to 190,900 kva. An addition to the station is now being completed to house three 35,300-kva. turbo-generators, two of which will be in service during the summer of this year and the third in March, 1924. The boiler plant is at the same time being increased by eight 1,800-hp. boilers.



MAP OF TERRITORY SERVED BY PUBLIC SERVICE ELECTRIC COMPANY

The company has recently purchased twenty acres of land adjoining its station property, on which a high-tension substation is to be erected. This additional space will also be used to increase coal-storage capacity, a spur from the Pennsylvania Railroad permitting the use of the 600 coal cars now owned by the company for transportation of coal from the mines directly to the station.

The Marion station is built on the banks of the Hackensack River, on the outskirts of Jersey City. Its largest unit at the present time is a 20,000-kva. horizontal machine, constituting a part of the 60-cycle capacity. Of the station's total capacity of 90,500 kva., 28,000 kva. is furnished by 25-cycle generators furnishing energy for railway use.

The station's boiler plant consists of fifty 600-hp. boilers, thirty of which are equipped with Roney and twenty with underfeed stokers. Coal, from both barge and cars, is handled by means of a gantry crane and horizontal and inclined belt conveyors and by the use of this apparatus may be placed either in overhead bunkers or in storage under the crane.

Extensions and improvements at Marion now in process include the installation of a new 25,000-kva., 60-cycle turbo-generator, a 12,500-kva., 60-25-cycle frequency changer to be used in connection with the 25-cycle load, and a new switch house to take care of the increased number of feeders going out from the station.

The Perth Amboy station, on the Raritan River at Perth Amboy, has a generating capacity of 22,500 kva. in horizontal turbo-generators, with eight 600-hp. boilers fired with chain-grate stokers. Coal is received by water and by means of an unloading tower and an inclined belt conveyor is unloaded into overhead bunkers. The Perth Amboy and Essex stations are tied together by a 26,400-volt transmission line.

The Burlington station is at Burlington on the Delaware River, at about equal distance from Trenton and Camden. It has a capacity of 37,500 kva. in three

horizontal turbo-generators of 12,500 kva. capacity each. Its eight 600-hp. and two 1,500-hp. boilers are fired by underfeed stokers. Coal is received at this station by rail and handled by a skip hoist and inclined belts.

The 1922 peak load for the company's generating stations came in December, when 249,778 kw. was carried.

### THE TRANSMISSION SYSTEM

The company's transmission system consists of approximately 957 miles of line, operating in part at 13,200 volts and in part at 26,400 volts, interconnecting the fourteen generating stations and the seventy substations of the company and supplying energy to such large customer installations as are fed directly from the generating stations. The seventy substations have a static transformer capacity of 572,875 kva. and a rotary converter capacity of 120,884 kw., exclusive of that of street-lighting transformers through which are fed 50,500 street lamps.

In the large cities a considerable length of underground cable, both 13,200-volt and 26,400-volt, is in use, while at many points in the transmission system where conditions do not warrant underground construction and where open wire-circuits cannot be used to advantage aërial cable, the cable being of the same type used underground, has been installed with exceptionally good results, interruptions to service having proved negligible.

The system's substations operate at 13,200 volts, and where it is necessary to step down energy from the 26,400-volt lines the company's practice is to install an outdoor type of substation. A typical station of this class is the Bayway substation in the factory district of Elizabethport. Here are installed two 3,750-kva. water-cooled units placed on concrete foundations immediately under the high-voltage buses. High-tension oil switches, aluminum-cell arresters and buses are all carried on steel framework set on concrete foundations out of doors.

In most cases the transformers step down the energy to 2,400 volts on the secondary side, automatic feed regulators, a switchboard, a 2,400-volt double bus and 2,400 electrically operated oil switches being housed indoors. In cases where it is desired to have the transmission transformers deliver energy to station and substation buses connected with incoming and outgoing feeders operating at 13,200 volts the transformation is at the ratio of two to one, giving a secondary voltage of 13,200. A large number of the substations are operated with a primary voltage of 13,200, stepped down to 2,400.

Until 1922 the company's standard of distribution was 2,400-volt, two-phase, four-wire service to customers being furnished at 2,400 volts, or through transformers at 220/110 volts, three-wire, except in the case of about twenty large users, supplied with three-phase service at 13,200 volts or 26,400 volts. In 1922, however, a new standard was adopted, and for a large part of the system a change was made to three-phase, four-wire, with 4,150 volts between phase wires and 2,400 volts to neutral wires, which are in all cases solidly grounded at the substation. The change involved much work, both in the substations and in installations of line transformers, but resulted in an increase of distribution line capacity of about one-half and a reduction in line loss of 67 per cent.

All of the company's three-phase and about 85 per cent of its single and two-phase circuits are equipped with automatic potential regulators, installed in substations, to assure adequate and uniform voltage to users.

### A DECADE'S GROWTH IN DEMAND

Increase in demand has during the last ten years been little short of astounding. As was to be expected in a community of the character, war industries greatly increased industrial requirements both for power and light. Conditions following the war slackened in some degree the demand, which has, however, during the last sixteen months been renewed to a greater degree than ever before.

In 1910 the per capita consumption of energy for other than street-railway purposes in the territory amounted to 46.5 kw.-hr. per year, and the company had in service a meter for each 30.9 inhabitants. In 1922 per capita consumption was 205.2 and a meter was in service for each 7.5 inhabitants. In 1910 the kilowatt-hours sold, exclusive of energy generated for street-railway purposes, amounted to 89,742,689 and meters in service were 63,186. In 1922 kilowatt-hours sold amounted to 534,465,033 and meters in service to 344,309—a gain of 495 per cent in energy sold and of 445 per cent in number of meters in service. In the first four months of this year the gain in meters has broken all records for the same season of the year.

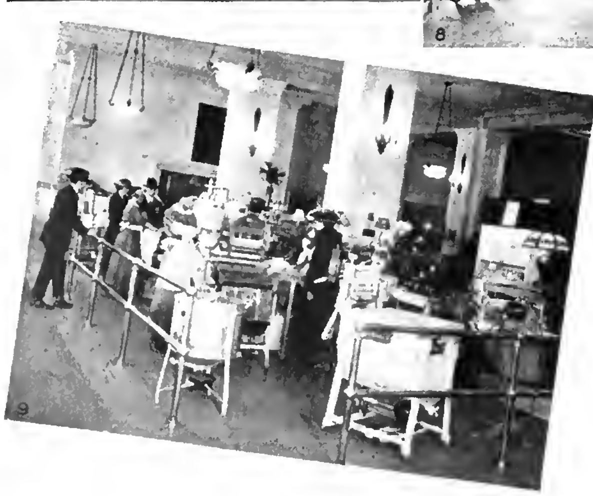
The development of the section of New Jersey served by the company is going on with increased momentum. Within a short time New York and New Jersey will be connected by a tunnel which will greatly increase ease of communication. A bridge to connect Philadelphia and Camden is under construction, and its completion will make the greater residential and industrial development of that portion of New Jersey surrounding Camden a certainty. The two states are now at work on the development of the port of New York, which lies largely within New Jersey waters. The port of Newark is already making a successful bid for increased business, while to further close the gap between New York and New Jersey projects for bridging the Hudson have gained substantial backing.

A survey of power requirements in the Public Service Electric Company's territory indicates for a number of years to come an increase in load demand upon the company of at least 30,000 kw. a year.

The company is laying its plans to keep pace with, or proceed a little in advance of, the needs of its territory. Within the last few months the Public Service Electric Power Company was organized by the Public Service Corporation of New Jersey, the parent company of the Public Service group of utilities, to construct and lease for 999 years to the Public Service Electric Company a new generating station with an initial capacity of 207,000 kva., to be enlarged within a comparatively few years to more than double this capacity. Within a short time construction work on this new plant will begin. The five units which will constitute the first installation will be two 45,000-kva. and three 39,000-kva. turbo-generators, all 13,200-volt, three-phase, 60-cycle.

The Public Service Electric Company feels that the industry is entering upon a phase of development in the use of electricity that is to be of stupendous importance both to the people of the country and to those within the industry itself, and that what is taking place in New Jersey is indicative of a general movement.

## Office Building and Showrooms of the New York Edison Company



THE showrooms of the New York Edison Company are located at advantageous points throughout the territory to afford the greatest convenience to customers: 1 and 8—Tremont Avenue display room, in the Bronx; 2—Bureau of Home Economics on the third floor at 124 West Forty-second Street; 3—Showroom on 125th Street; 4—Showroom on 149th Street near Third Avenue in the Bronx; 5—General office building, Fifteenth Street and Irving Place; 6—Appliance display room at 124 West Forty-second Street; 7—East Eighty-sixth Street office; 9 and 10—Showroom at Fifteenth Street and Irving Place.

# Metropolitan Merchandising

## A Review of the Policies Adopted and the Recent Activities in Selling Appliances Carried on by the Various Central-Station Companies Operating in the New York Metropolitan District

THERE is an exceedingly interesting situation in the metropolitan district as regards the merchandising of electrical appliances by the central-station companies. There are five electric light and power companies in or about New York City that may logically be considered in the group—the New York Edison Company and the United Electric Light & Power Company on Manhattan Island and in the Bronx, the Brooklyn Edison Company in Brooklyn, the New York & Queens Electric Light & Power Company in Long Island City, and across the Hudson River, with headquarters in Newark, the Public Service Electric Company. Each is confronted with conditions rather different from those confronting the others, and there is a considerable diversity of merchandising policy between them.

The Brooklyn Edison Company and the Public Service Electric Company are actively engaged in merchandising appliances for profit. The United Electric Light & Power Company is also selling appliances energetically, but profit is made a minor consideration. The New York & Queens Electric Light & Power Company merchandises appliances on a profit-making basis in its salesrooms, but is devoting most of its attention now to wiring old houses and obtaining customers in a very rapidly growing territory.

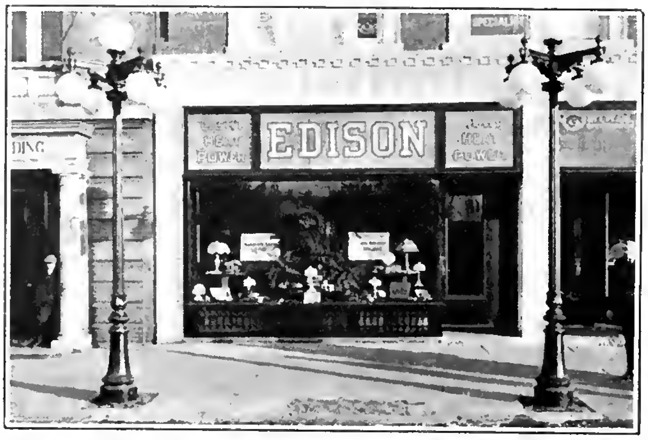
The New York Edison Company for many years has maintained display rooms and actively demonstrated appliances to the public, but for some time has not engaged in any merchandising activity. Recently, however, a new policy has been inaugurated under which household appliances of all kinds are being sold out of the Edison shops on deferred payments, charged with the monthly service bills. This merchandising, however, is being done in behalf of the manufacturer with consigned stock and does not pass through the books of the Edison company. A detailed statement of the Edison company's present attitude and policy toward merchandising by Arthur Williams, general commercial manager, appears on page 1211 of this issue.

### NEW YORK EDISON POLICY

The Edison shops and the Edison policy on merchandising will be of particular interest to utility men attending the convention. In the early days of central-station commercial activity the New York Edison Company sold appliances just as it sold power, lighting, signs and other applications of the service. With the rapid growth of the business and the increase in the appliance line, the Edison company withdrew from the merchandising field and turned over the entire function of retailing energy-consuming appliances to the local contractors and dealers. Since then the company has maintained its showrooms for display and demonstration purposes only. The devices have been shown but not sold, and customers have been referred to the dealers or manufacturers and orders have been taken on memorandum for delivery by the manufacturer or dealer.

APPLIANCE SALESROOMS OF THE UNITED ELECTRIC LIGHT & POWER COMPANY. LEFT, SHOWROOM ON FIFTH FLOOR 130 EAST FIFTEENTH STREET. RIGHT, SHOWROOM AT EIGHTY-NINTH STREET AND BROADWAY

The Edison company therefore has stood before the industry as probably the foremost exponent of the policy opposed to the merchandising of appliances by the utility. However, the American people have undoubtedly adopted the easy-payment plan as the method by which they prefer to purchase household equipment, and this policy of the Edison company has naturally made it harder for its customers to acquire electrical appliances than it is for customers of another utility that sells on deferred payments, charged with the service bills. A few months ago therefore the Edison company informed its customers and began to advertise in its stores that appliances could be purchased by consumers for a small cash payment and the balance in deferred payments monthly. Deliveries are made by the manufacturer or the dealer by whom the device purchased has been consigned, except in urgent cases where the customer wishes to take the appliance away immediately. To



ONE OF THE BROOKLYN EDISON COMPANY'S SALESROOMS

provide for such cases a small consigned stock is kept on hand.

The New York Edison Company supports the appliance market with generous advertising, displays, demonstrations and lectures, and it plays the major part in an annual electric show. The company operates a main salesroom at its general offices and has a number of branch showrooms throughout the city.

### UNITED COMPANY'S POLICY

The United Electric Light & Power Company serves 75,000 residential consumers in the uptown section of New York, with a very large proportion of apartment-house customers. The company maintains three salesrooms, twelve inside appliance salesladies and twenty outside appliance salesmen, and operates two wagon crews of eight men each. About $350,000 in appliances has been sold in the last twelve months. The company advertises extensively in the newspapers, direct by mail and on billboards, many of these displays featuring electrically operated clocks to attract attention. It takes active part in the annual electrical show and does much demonstration work.

The chief merchandising effort is made through monthly sales in which a particular appliance is featured at special inducements. Advertising matter is sent directly by mail to all customers, with an easy-payment

OFFICE OF THE NEW YORK & QUEENS ELECTRIC LIGHT & POWER COMPANY AT FLUSHING, L. I.

offer, and the wagon crew sells from house to house, using the special appliance of the month as a leader. A recent survey of all residences served by the United company led to a very energetic drive to fill up the empty sockets on the lines, and this greatly increased lamp sales.

### BROOKLYN EDISON ACTIVITIES

The Brooklyn Edison Company has been one of the most active of the metropolitan central stations in the sale of merchandise and in the last two years has increased its retail appliance business greatly. The company operates a main appliance shop at its general offices and is now erecting a very handsome new building, the conspicuous feature of which will be a large appliance store. There are also seven branch offices with salesrooms.

In 1921 the Brooklyn company sold nearly 25,000 appliances. Very satisfactory results were received from the house-to-house canvass by crews of salesmen working on commission. For several years it has been the practice of this company to conduct a special sale each month, featuring a specific appliance. This device has often been a special purchase for the sale, but has been sold at list price at a profit, and the privilege is

VIEW IN THE APPLIANCE SALESROOM OF THE PUBLIC SERVICE ELECTRIC COMPANY, NEWARK, N. J.

extended to the local dealers to take orders for this device at the same price and at a profit.

Remarkable results have been achieved in Brooklyn through the operating of a wagon crew. Forty men work from one wagon, carrying appliance samples to assigned blocks, returning to the wagon when the sale is made for a new sample. Post cards are received through the advertising, and these leads are used in the wagon selling. For each sale made on "cold canvass" the salesman receives a special assignment to a block from which a post card has been received. The location of this lead is not told, however, and the salesman canvasses the block until he finds it. These men, calling at the customers' homes, have made 40 per cent of all sewing-machine sales, an even greater percentage of vacuum-cleaner sales, and virtually 90 per cent of all clothes-washer sales. They work by the day on salary and commission.

The Brooklyn company last June conducted a sewing-machine school that proved an interesting innovation. A course of four lessons was given, and 153 pupils completed the course. There were also eighteen visitors, four of whom purchased electric sewing machines. In-

struction was given to 52 per cent of the women who bought sewing machines last year.

NEW YORK AND QUEENS POLICY

The New York & Queens Electric Light & Power Company maintains an appliance saleroom in each of its offices in Long Island City, Jamaica, Flushing, Bayside and Ridgewood. All merchandise is sold at a profit and mostly for cash. Only a few outside salesmen are employed by the company, but the manufacturers of standard appliances all carry on an active campaign resulting in large aggregate sales to its consumers, who have increased rapidly in the past five years. The company, however, plans as it approaches more nearly to the so-called saturation point to expand its merchandising activity and materially enlarge its sales force.

MERCHANDISING IN NEWARK

The Newark territory of the Public Service Electric Company is essentially a part of the great metropolitan district of New York. The company operates also throughout a large part of the State of New Jersey, which has necessitated a somewhat different commercial organization than that of the companies already discussed. It comprises a number of divisions in which there are district offices in all the important communities, with salesrooms in which active merchandising is carried on. A great deal of attention has been given by this company to the development of appliance business, and this is one of its principal commercial interests. There are eighty-seven combination salesmen on the staff selling both electric and gas appliances, fifty-one special appliance representatives selling only vacuum cleaners and washing machines, and thirty-nine people employed in selling in the various display rooms.

The Public Service Electric Company has made a notable success in campaign sales. In 1922 a special drive sold 22,000 flatirons, and the sales so far this year indicate a total of 25,000 for 1923. Last year the company sold 7,150 vacuum cleaners, and it has set the bogey for 10,000 cleaners for 1923, with 3,925 gone by April 30. A special percolator sale that began in April disposed of 196 in the first three weeks. In all, 72,639 appliances were sold in the last year.

These sales are all very carefully planned. A general outline of the new business plans goes out to all

## A Statement of The New York Edison Company's Merchandising Policy

**THE news that electrical appliances are now being sold on the deferred-payment plan in the showrooms of the New York Edison Company has naturally been received with great interest by electrical men, inasmuch as this company has long been looked upon as opposed to the sale of merchandise by the central station. The ELECTRICAL WORLD, therefore, invited Arthur Williams, general commercial manager of The New York Edison Company, to submit a statement of his company's policy on appliance merchandising for publication at this convention time. Mr. Williams says:**

In the merchandising of electrical appliances the New York Edison Company continues, in principle, a policy adopted a number of years ago when the company definitely gave up contracting for installations and the sale of fixtures, motors and other appliances. It did this in the belief that in opening the New York field to the electrical contractor and to manufacturers of fixtures and appliances, and thereby eliminating itself as an element of competition, it was serving not only its own interests and those of the general public, but also the larger interests of the electrical industry, broadly speaking. To the company it seemed that it should devote itself to the generation and distribution of electrical energy as its principal merchandising effort. I believe there has been no reason to regret taking this step, although at the time it appeared almost revolutionary, inasmuch as it was apparently eliminating a legitimate activity and deprived the company of large revenue, both existing and prospective.

But coincident with the adoption of this policy, the company recognized that it must continue its best endeavors to create a permanent demand for electrical energy on the part of the public in as many different directions as possible. Therefore it employed the best available agent of publicity—the public press—meanwhile not neglecting the very wide range of other advertising methods in the way of text and illustration—to inform the public of the advantages of electric service and of the constantly increasing appliances for its economic utilization.

As a matter of fact, what may be called the company's intensive merchandising effort is concentrated upon three points: First, of course, the providing of the best service attainable at the lowest possible prices; second, the constant effort, in the light of the most approved forms of publicity, to create a desire for electrical service and to see to it that means of satisfying this desire are adequate and conveniently placed; third, the maintenance of a competent organization to retain customers once secured and prepared to meet any question indicating a feeling of dissatisfaction with the company's service in such manner that the customer shall continue satisfied with our service. One of the results which we attribute to our policy of concentrating our merchandising efforts upon the points just outlined is the establishment of approximately 2,500 contracting and merchandising dealers in New York City. The number increases annually, and the character of the service rendered, the premises where exhibits are on display and the exhibits themselves are all constantly improving.

It has been urged that the New York Edison Company, following the example of many other central-station organizations, should abandon its policy of encouraging independent agencies and engage in direct merchandising. Undoubtedly, a very wide development along such lines could be attained. But activity of that character would require that the company confine its selling efforts to one, or at most a very few, types of appliances or apparatus. The company feels that it should always be helpful in the merchandising of all approved appliances.

In the company's showrooms, at the moment, there are on exhibition no fewer than twenty-four types of vacuum cleaners from as many different manufacturers; there are twenty-three types of washing machines and twenty-one types of electric irons—to mention only three of a very long list of appliances on display. During the past month sales have been consummated in the interest of seventy-four different manufacturers or agents who are making use of the facilities of the company's showrooms in order to reach the New York public.

One of the principal obstacles in the use of electric service is the initial cost of equipment and appliances. For many years the company has advanced funds which prospective customers require for wiring their premises, to be repaid on the installment plan. Recently this privilege has been extended to purchasers of new household appliances. In the case of appliances, however, credit is confined to customers in good standing. Today, therefore, no one need deprive himself of either electric service or any kind of household equipment on the ground of first cost. Here again, as when the purchaser himself makes full and immediate payment, the customer chooses what he wishes to use, the company receives and transmits his order to the manufacturer or agent and, upon satisfactory fulfillment of the order, pays the bill, being paid in turn by the customer.

Had not the present course of independent merchandising development seemed more desirable from the standpoint of the public at large, the customers of the company and the company itself, it surely would have been changed. In view of the fact that the company desires to follow such policies as best serve all, the present methods will be changed should others be found more useful and effective in carrying out the purpose of attaining the ideals which have been established as standards of possible attainment in our company's branch of New York's public utility service.

ARTHUR WILLIAMS,
*General Commercial Manager,*
*The New York Edison Company.*

offices three months before the drive starts, and special meetings are held to organize friendly competition between divisions. All the campaign work is backed up strongly with newspaper and direct-by-mail advertising, which is written after the style of department-store and mail-order copy. During one vacuum-cleaner sale a broadside folder went to 150,000 customers. But results have been gained for this company by specialization, and a separate crew is now being organized to sell domestic refrigeration. Other special crews are planned for other large appliances that are stiil in the pioneering stage, such as the fireless cooker, the ironing machine and the dishwasher. These crews will be put to work as the demands for these devices justify it.

In short, the general aspect of central-station appliance merchandising among the companies serving the New York metropolitan district is typical of the appliance situation throughout the industry. Steadily increasing attention is being given to the development of the residence appliance load, and in order to build up household utilization of electric service for labor saving, cooking and comfort the light and power companies have found it necessary to engage in the retail sale of electrical merchandise on a large scale. The success which has attended this work, especially where the business has been put on a strictly merchandising basis, has been such that the scale of the operations has steadily increased and indicates a continued expansion.

# Electric Trucks in Greater New York

## A Record of Remarkable Progress in the Introduction of Battery-Driven Vehicles —What the Rapid Growth of this Movement Means in Augmenting the Central Station Load

TRANSPORTATION in New York City has become a problem to which both city officials and engineers are devoting a great deal of attention, and the electric vehicle bids fair to play no small part in speeding up deliveries and relieving to a marked degree the congestion of the streets. The adaptability of the "electric" to the short-haul, frequent-stop city delivery makes it peculiarly suitable to the prevailing conditions, and although the number of electric trucks now in use is but a small percentage of the total, they are each year coming into more and more general use by business houses that make a careful analysis of their costs of delivery.

The accompanying tabulation, showing that there are now in use in New York City a total of four thousand electric vehicles, also shows the various kinds of business which have found it economical to adopt electrics for their delivery service.

### New York Edison Company a Pioneer

The New York Edison Company has long been an active advocate of the electric vehicle and believes in setting an example in this respect, for it uses in its own service a fleet of 121 electric trucks of all sizes. In the promotion of this business the company has organized an electric vehicle bureau in which four men are engaged, in co-operation with the manufacturers, selling trucks. In 1922 the company sent out more than one hundred thousand sales letters, and the company's records show that one thousand electric vehicles have been sold in the metropolitan district during the last two years.

NUMBER OF ELECTRIC TRUCKS USED IN NEW YORK CITY

| | |
|---|---|
| Department stores (seventeen) | 383 |
| Bakers (fourteen) | 479 |
| Bottling companies (twenty-nine) | 561 |
| American Railway Express | 400 |
| New York Edison Company | 121 |
| Eleto Company (department-store delivery) | 54 |
| Consolidated Gas Company | 52 |
| Westcott Express Company | 51 |
| Bush Terminal | 36 |
| United Electric Light & Power Company | 31 |
| New York Transfer Company | 29 |
| National Biscuit Company | 28 |
| Horn & Hardart (restaurants) | 27 |

| All others | 1,699 |
| Total | 4,000 |

ELECTRIC TRUCK AND DERRICK USED BY THE EDISON COMPANY TO HANDLE CABLE REELS AND FOR OTHER HEAVY WORK

There are now in operation in New York eight electric garages, housing 275 cars and consuming a half million kilowatt-hours annually, netting the central-station companies more income than they receive from four thousand houses, or as many houses as there would be along 30 miles of street. What the use of the electric vehicle means in energy consumption in New York City is shown by the fact that in 1922 energy in excess of 4,000,000 kw.-hr. was used in the charging of vehicle batteries. Sales of electric trucks during the first three months of 1923 totaled 225, as against only sixty-four during the same period a year ago.

Express and trucking companies, department stores, laundries and provision dealers have been among the largest buyers of electric vehicles. Typical instances

of the adoption of the "electric" are interesting as they show the tendency to use them rather than gasoline or the horse-drawn vehicle. The Pilgrim Laundry, which is one of the largest laundries in Brooklyn, has completely motorized its delivery. It now owns thirty-eight electric and only four gasoline cars, or better than 90 per cent of its trucks are electric.

The American Railway Express Company is the largest single user of electric vehicles in Greater New York, and 83 per cent of all its motor vehicles now purchased for the metropolitan district are electrically propelled. This company is working to a virtually complete electrification of all its trucks used in the congested districts which prevail in a city such as New York.

A large baking company in Newark, N. J., last winter placed an order for a fleet of 177 electric trucks and forthwith advertised for sale all of its gasoline and horse-drawn equipment. It has been the experience of this company that the electric vehicle is not only much cheaper to operate and maintain, but that it can cover a given route much faster than a gasoline truck, owing to the fact that in congested traffic it can start and stop quicker than the other car. This observation has held true even on the longest routes with the less frequent stops.

### Obstacles Disappearing

Many conditions which heretofore have been detrimental to or have affected adversely the sale and use of the electric vehicle have been overcome within the last year. With the development of the high-speed gasoline truck it was felt for a time that the "electric" could scarcely compete with it, but this very characteristic has proved to be more of a hindrance than a help in cities and the electric truck is now coming into its own.

Another obstacle which has been overcome is the lack of information and data on the operation and maintenance of electric vehicles. The organization of an electric vehicle school in New York last winter was a big step forward in making this much-needed knowledge about the electric truck available. The popularity of the school may be judged by the fact that it had an enrollment of three hundred, whereas only about forty men had been expected to attend. It was conducted in conjunction with the Vehicle Bureau of the National Electric Light Association, and most of those who attended were operators and maintenance men sent by vehicle owners. A number came from other central-station companies.

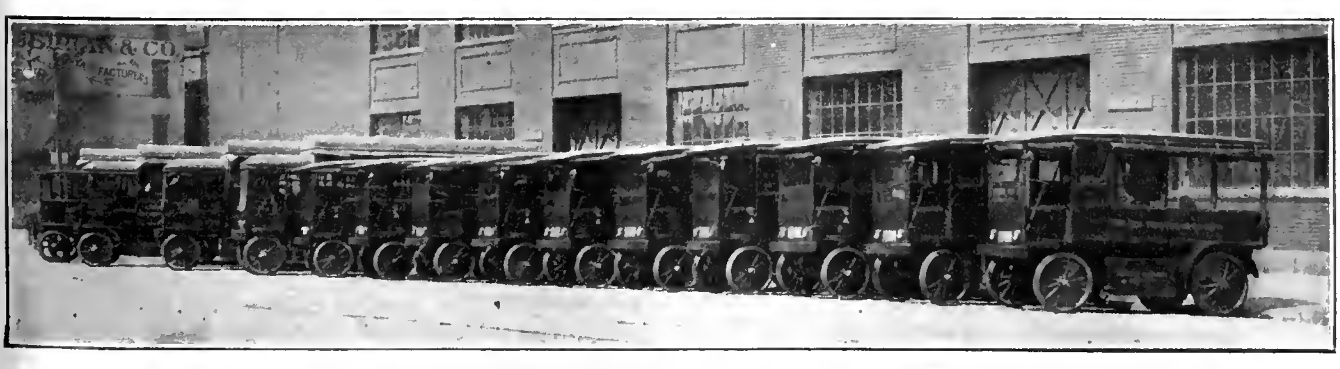
The central-station man himself has been slow to push the electric vehicle, although he has recognized its possibilities as a load builder. That this attitude is changing rapidly is seen in the fact that in the last twelve months central stations in the metropolitan district have bought a hundred electric trucks and that fifteen central stations in the United States have bought a total of 250 trucks.

INDUSTRIAL ELECTRIC VEHICLE SHOW IN PUBLIC SERVICE ELECTRIC COMPANY'S SHOWROOM, NEWARK

### Vast Market Ahead

While it is becoming increasingly evident that the electric vehicle will play an active part in the solution of New York City's transportation problem, its use is still in its comparative infancy and there is plenty of room for growth. A recent survey by the engineers of the New York Port Authority disclosed that 72.7 per cent of the commercial vehicles used in New York City are still horse-drawn, 25.8 per cent are gasoline trucks and only 1.5 per cent are electric. There is no doubt that all of the horse-drawn vehicles could be replaced economically by electric vehicles or that a large part of the work done by gasoline trucks could be profitably and more economically done by the "electric." This means that from 80 to 85 per cent of the transportation of goods in New York City streets should fall to the lot of electric vehicles.

With the additional electric vehicles which have been sold this year, The New York Edison Company estimates that approximately 10 per cent of the trucks in use in New York City and surrounding territory are of that kind. Taking the entire country over, only 2 per cent of the total number of trucks in use are electric. There should be, it is conservatively estimated, 200,000 electric vehicles in the United States, averaging an energy consumption of 6,000 kw.-hr. per truck per year. This means that here alone is a potential market for the central-station companies to sell 1,200,000,000 kw.-hr. annually by the proper development of the vehicle load, nearly all of which would come at off-peak hours and at a very profitable rate per kilowatt-hour.



A FEW OF THE ELECTRIC TRUCKS USED BY THE NEW YORK EDISON COMPANY

# Power Development in New York City

## Large Buildings Housing Many Small Manufacturers Create Unusual Conditions—Refrigeration Load Has Grown Rapidly—Private Plants Are Fast Giving Way to Service from the Central-Station Companies

BECAUSE it is primarily a commercial and financial center, Greater New York presents a power problem to the central-station companies that differs in many respects from that found in cities where industrial activity is more predominant. As might be expected in a city of these characteristics, particularly on Manhattan Island, the greater number of important electrical installations are in office buildings, commercial structures, hotels, department stores, apartment buildings, places of amusement and so forth. The metropolitan district, however, must be considered as including not only Manhattan, the Bronx and Brooklyn, but Queens County and the contiguous territory across the Hudson River in New Jersey as well, for it is to the two latter territories that the growing manufacturer of New York City must turn to find room for industrial expansion, and it is there that typical industrial power applications in the usually accepted sense are developing.

The New York Edison Company supplies energy in Manhattan Island from the Battery to 136th Street and in the greater part of the Bronx. With the exception of a comparatively few customers supplied under high-tension contracts, the service in Manhattan is direct current. In the Bronx it is alternating current.

Among some of the large primary power customers which are supplied by The New York Edison Company are the Third Avenue Railway, the Hudson & Manhattan Railroad Company and several plants of the American Ice Company, one of which has a demand of 1,828 kw. during the summer months. Nearly all of the larger refrigerating businesses have been taken over by the company since 1916, when it became evident to the ice manufacturers that the use of central-station service would be far more economical than the operation of private steam plants.

Other power users supplied with direct current make up a large volume of business of a highly diversified nature, and it is interesting to note that manufacturers of the same or closely related products have gravitated toward each other until they have formed districts given over to their particular class.

BANK OF ELEVATOR MOTORS IN THE CUNARD BUILDING, WHICH USES EDISON SERVICE

### SECTIONS OF THE CITY DIFFER

In a broad sense, Manhattan Island may be considered in three general sections—the downtown, in which the largest office buildings are located; the uptown, which is in the main residential, and the midtown, having some of the characteristics of the two other sections, with many others distinctly its own. In the last-named zone are to be found many large office structures, most of the theaters of the city, substantially all of the department stores, many apartment houses, and a large and important grouping of manufacturing loft buildings. In it is also located the center of the printing industry.

A recent review of the large buildings in the part of this district lying between Twenty-eighth and Fifty-ninth Streets and extending from river to river gave a fairly comprehensive idea of the character of the installations supplied by the Edison company. The largest grouping of important structures comprises 440 loft buildings, some of which reach a height of twenty stories. Of this number 350 are devoted to manufacturing purposes, including printing, and ninety to commercial purposes—salesrooms, offices, etc. Second on the list are the apartment houses, of which there are 275. Next is the office building group, which contains 205 structures, followed by the theaters, of which there are sixty-two. Completing the list are fifty-five hotels, twenty-two motion-picture houses and nine department stores. The electrical installations of the largest of these buildings run up to from 2,000 kw. to 3,000 kw.

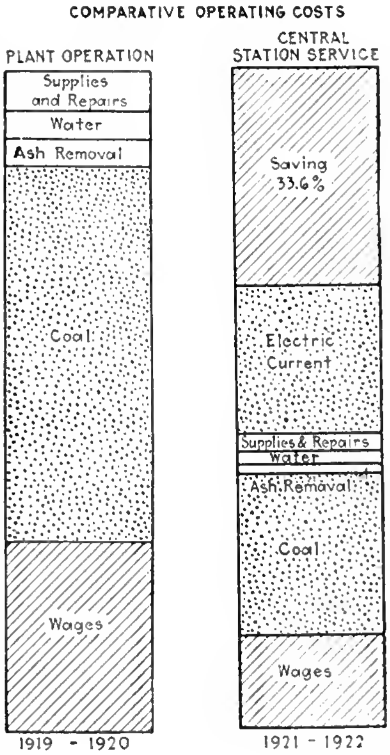
A very large proportion of New York's manufacturing is done in buildings of the manufacturing loft type, the units being comparatively small. The census figures show that in 1919 there were in Manhattan and the Bronx 24,382 manufacturing establishments, having an average of 13 hp. per establishment, while the average in a group of other large cities was 90 hp. per establishment.

The foremost industry of the city is garment manufacturing, and this is practically all carried on in these manufacturing loft buildings, nearly all of which use central-station service. Excellent examples of this type of building are the two huge structures of the garment center on Seventh Avenue from Thirty-sixth to Thirty-eighth Street. Here may be found in one service unit a large group of manufacturers of wearing apparel whose combined electrical requirements, including the building equipment, total 2,650 kw.

Second in rank are the printing and publishing trades. With the removal of the New York *Tribune* from its former location in Nassau Street to its new building on West Fortieth Street it became a customer

of The New York Edison Company, which now, with this acquisition, supplies every large newspaper in Manhattan. In general commercial printing and in the publishing of magazines and books central-station service is also predominant. The electrical requirements of these large newspaper and printing buildings, of which there are more than half a hundred in the city, run as high as 2,500 kw.

In Manhattan building operations during the past few years have been principally in the direction of office, loft and apartment construction, the latter of the more expensive kind. Many of the structures erected in this period will undoubtedly occupy permanent places in the list of New York's prominent buildings. Among them may be mentioned the Cunard Building, at 15-25 Broadway; the Pershing Square Building, Forty-second Street and Park Avenue; the Cotton Exchange, 60-62 Beaver Street; the Standard Oil Building, still in course of erection at Broadway and Beaver Street. All these and very many others are supplied with central-station service.



TYPICAL SAVINGS EFFECTED BY ABANDONING PRIVATE PLANT

## PRIVATE PLANTS DISAPPEARING

The private plant, while still a factor in large building service, is becoming less and less so year by year. In the last ten years the number of private plants installed in Manhattan and the Bronx in new buildings has averaged about two yearly. Contrasted with this is the record of twenty years ago, when during 1902 fifty-three private plants were installed in new buildings. This change in the situation is the more significant when it is remembered that the average size of the buildings erected in the city is very much greater now than it was twenty years ago.

Accompanying this decrease in the number of new plants arranged for is the constantly growing number of private plants abandoned in favor of central-station service. The New York Edison Company's records show a total of about eight hundred private generating plants shut down, of which about three hundred have been abandoned in the last five or six years. All sorts and sizes of buildings are represented.

The number of plants abandoned, while composing a fairly formidable list, would unquestionably be much larger were it not that when many of New York's large buildings were erected hydraulic elevators were installed as the best type then available. The owners of these properties are now faced with the necessity, if their generating plants are shut down, of electrifying the elevators or continuing in operation their high-pressure boilers and elevator and pumping equipment, the latter course making it difficult to realize the full measure of saving. While the alternative of installing new electric elevators or electrically operated pumping equipment involves a large initial outlay, the advantages are so pronounced that during recent years several hundred hydraulic or steam elevators have been changed to electric operation, the expenditures for this purpose running into hundreds of thousands of dollars.

In the Bronx district the principal growth during several years past has been along residential lines, the apartment-house construction in that section having broken all previous records by a wide margin. Included in the list are the new Roosevelt Apartments, widely advertised as the largest apartment house in the world. This building covers an entire city block, accommodates 260 families and has a lighting installation of more than five thousand lamps.

The manufacturing load in the Bronx is an important and constantly growing one, central-station service having been adopted not only in virtually all the new factories erected within recent years, but in a large number of older ones as well, which were formerly supplied from private plants.

The load of the factory plant business taken over during the past five years totals approximately 12,500 hp. distributed among 130 manufacturing establishments

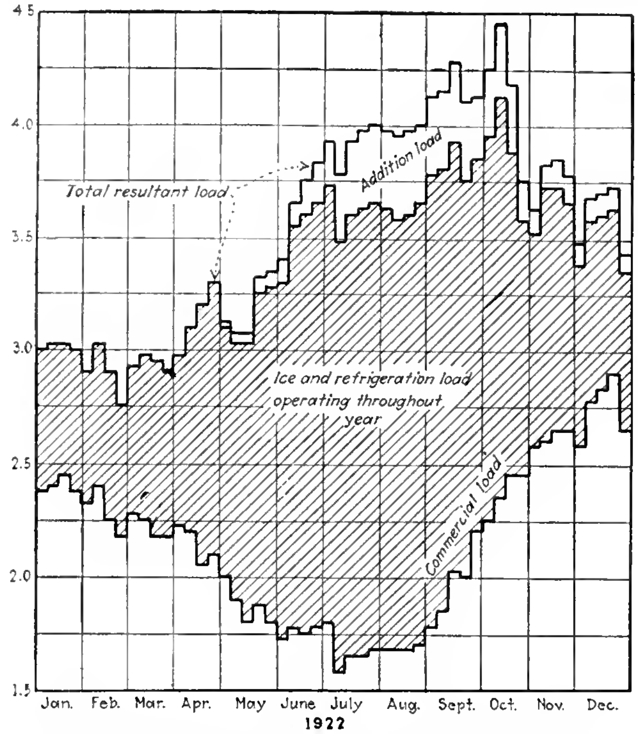
## THE UNITED ELECTRIC LIGHT & POWER COMPANY

The United Electric Light & Power Company, which produces alternating current only, overlaps the territory of the Edison company and supplies service to the extreme northern end of Manhattan Island. The company wholesales a large amount of high-tension power to other utilities, including The New York Edison Company, and supplies power to the New York, New Haven & Hartford Railroad Company for the operation of its electrified division as far as Cos Cob, Conn. The ice and refrigeration business, because of its desirable load factor, has had especial attention in the sales efforts of the company. The largest ice plant in the world is one of the United company's power customers. The results

TABLE I—UNITED COMPANY'S REFRIGERATION LOAD

| Year | Customers | Added Hp |
|---|---|---|
| 1917 | 0 | 0 |
| 1918 | 18 | 11,425 |
| 1919 | 42 | 10,430 |
| 1920 | 53 | 4,517 |
| 1921 | 62 | 8,485 |
| 1922 | 77 | 9,035 |
| Total | | 43,892 |

OLD PRIVATE PLANT REPLACED BY CENTRAL STATION POWER



HOW THE ICE AND REFRIGERATION LOAD FILLS UP THE VALLEY FOR THE UNITED ELECTRIC LIGHT & POWER COMPANY

as reflected in the connected load of the company's commercial business are shown in the accompanying analysis (Table I), showing the amount of this business added during the last five years.

During the past year special interest has been devoted to contracts for the manufacture of ice cream, one of the components of the ice and refrigeration business. In this period of twelve months 1,300 kw., representing a gross revenue to the company of $39,000, was added to the company's lines through this medium.

### Ice and Refrigeration Business Big Item in 1922

The high-tension ice and refrigeration business for 1922, as represented by twenty-seven plants supplied by the company, totaled an annual consumption of 73,804,520 kw.-hr. in commercial load.

The figures presented above apply only to the Borough of Manhattan and are exclusive of power supplied to allied organizations. The annual load factor of the high-tension ice and refrigeration business is 55 per cent as against the load factor of the entire commercial low-tension business of only 33.8 per cent. The average weekly load factor for all high-tension ice and refrigeration business for 1922 was 80 per cent. How the company's commercial power load is divided is shown in Table II. Service to large apartment houses makes up no mean portion of the United company's load and is increasing rapidly each year.

BATTERY OF THREE BRASS MELTING FURNACES ON THE LINES OF THE NEW YORK & QUEENS ELECTRIC LIGHT & POWER COMPANY

TABLE II—CLASSIFICATION OF COMMERCIAL POWER LOADS ON UNITED ELECTRIC LIGHT & POWER COMPANY'S LINES

| Kind of Load | Per Cent of Total |
|---|---|
| Ice and refrigeration | 59.0 |
| Woodworking | 8.3 |
| Provisions | 3.2 |
| Metals and furnaces | 8.8 |
| Tobacco, chemicals and laundry | 5.7 |
| Construction work (temporary) | 6.0 |
| Telephone exchanges | 3.7 |
| Glass and marble | 0.3 |
| Miscellaneous | 5.0 |
| Total | 100.00 |

Further extension of the power business in New York is now being developed through increasing the means of utilization of electrical energy by existing customers. In this respect vulcanizing and small heating applications, the use of glue pots, soldering irons, individual ventilating fans and small refrigerating plants offer an almost unlimited field. To develop this business The New York Edison Company has recently adopted a policy of selling this equipment to its customers, at the same time offering them the opportunity to pay for it on the deferred-payment basis.

### Brooklyn Edison Company

The Brooklyn Edison Company maintains a commercial engineering bureau which handles all power in excess of 10 hp. It compiles data regarding the development of large commercial installations and follows up the erection and equipment of all new buildings in the borough, maintains a "follow-up" of all existing customers by periodic calls, develops additional consumption of existing large customers, tests independent private plants, prepares engineers' reports, and follows up the development of federal, state and city public works and general large installation plans.

During the year many private steam generating plants and steam and gas engines were replaced by Edison service. A number of large original contracts were obtained, the principal ones being: Gowanus Canal Terminal, 3,000 hp., and Williamsburg Bridge municipal trolley line, 2,250 hp.

### Long Island and New Jersey

The New York & Queens Electric Light & Power Company is building up a substantial power load in the plants of manufacturers whose operations require more space than is available on Manhattan Island. Here the typical industrial equipment is found, and one of the recent installations shown here is a battery of three brass melting furnaces in the plant of the Neptune Meter Company.

In New Jersey the Public Service Electric Company has a wide diversity of power business and during the war played an important part in supplying power to shipyards, munition plants and other war industries. Among the large customers of the company is the Crucible Steel Company, which has a demand of 15,000

kw. There are many other large manufacturers among the company's power customers. So great has been the demand for power that the company is now installing three 33,000-kva. generators in its Essex station, two of which are to be in operation this year and the third early in 1924. The Public Service Electric Company also has perfected plans for another entirely new plant, the initial capacity of which will be 200,000 kw., with provision for expansion to 400,000 kw.

The magnitude of the use of energy in the metropolitan district becomes apparent when it is considered that in December, 1922, the five central-station companies had a combined peak demand of 947,150 kw. and their total output for the year was 3,254,675,938 kw.-hr. This is exclusive of the energy generated in the plants of the street railways, elevated and subway companies.

## House Wiring and New Homes Add 130,000 Customers

With the number of apartment houses increasing and the private homes decreasing each year, particularly on Manhattan Island and in the Bronx, the field for wiring old houses in New York is in a measure restricted. It must also be remembered that in a number of apartment houses energy is sold through one meter to the landlord, who sells to the tenants through his own meters. Such residential customers do not show on the companies' books. The central stations, however, have been very active in offering easy terms to owners of unwired houses.

The New York Edison Company and the United Electric Light & Power Company have been making extensive surveys on their lines and have taken a number of wiring contracts on the deferred-payment plan. These companies do no wiring themselves, but contract with the customer for the business, which is turned over to the electrical contractor.

The Brooklyn Edison Company last October conducted a special house-wiring campaign in which the company financed wiring accounts on easy payments and supplied the contractors with forms for handling the business. The terms offered were 15 per cent down and ten months to pay the balance. A 5 per cent discount was allowed for cash on completion of the work. About 20 per cent of the business taken was on a cash basis.

In Queens Borough the New York & Queens Electric Light & Power Company is making an active canvass of the entire territory and turning this business over to the contractors. The company has not adopted any deferred-payment plan, but during 1922 6,688 old houses were wired and connected to the company's line.

The Public Service Electric Company some time ago retired from the active solicitation of house wiring in order that more attention could be given to the sale of electrical merchandising and current-consuming devices.

During the year 1922 the four companies operating in Manhattan, Brooklyn and Queens Borough, Long Island, connected to their lines 130,000 new residential customers, divided approximately as follows: Brooklyn, 63,000; Manhattan and the Bronx, 35,000, and Queens Borough, 32,000. These new customers, if they were taken together, would make a city of 600,000 people, and, estimated at a cost for wiring of $100 per customer, they represent $13,000,000 of wiring business alone in Greater New York.

# Letters from Our Readers

A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute

## Careless Advice from Power Companies on Equipment

*To the Editors of the* Electrical World:

Although we are not actually a part of the electrical industry, we have, in a way, a more or less indirect interest in a matter in which we believe there is considerable room for improvement in that industry. We manufacture a line of small air compressors sold to the garage trade, filling stations, small manufacturing plants, air-brush painters, users of pneumatic water systems and customers of a similar sort. These customers must buy power to operate their outfit. In sending us the order the customer often fails to specify the current characteristics or gives current characteristics which we are satisfied are not proper, and we tell him to consult his power company as to what current will be available for this size and type of motor. The customer secures this information from the power company, passes it on to us, and we furnish the motor accordingly. Then in a great many cases, entirely too many, we find that the power company has not given the correct information, or did not investigate the situation carefully enough for its prospective customer, or simply "shot up in the air" in the matter, so that, as a result, the customer has to exchange his motor for another one.

The writer has on his desk today papers concerning two cases of this kind. One of these is in Ohio, where the power company advised the prospective customer (its customer as well as ours) that he could install a ½-hp., three-phase motor to drive his air compressor, and then, after he had bought such a motor, told him that he would have to send it back and get a single-phase motor, because there was only a single-phase line available at that point. Another case occurred in Texas, where the same situation arose. Now, ½-hp., three-phase, 110-volt motors are not very good stock, and we are not interested in taking them back, which we would have to do in exchanging single-phase motors for them. In another case just the other day in Michigan the same circumstances arose and the power company, in the language of our jobber and our customer, was very "hard-boiled" about the matter. It didn't seem to care that it had given the customer the incorrect information.

We think the power companies ought to give their prospective customers just as much courtesy and attention and make as much effort to give them correct information as a manufacturer who is trying to sell this same customer a piece of equipment. We do not see that simply because the company is a public utility, with no competition, instead of a manufacturer, there should be any less reason for courtesy and correct information. Such a basic idea is all wrong.

We should appreciate it if the Electrical World would start the ball rolling and preach the gospel of a little more attention from the new-business departments of these power companies to the prospective customer who is looking for information.

Curtis Pneumatic Machinery Company, St. Louis, Mo. — Walter C. Hecker, Vice-President and Sales Manager.

# Central Station and Industrial Practice

**Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants**

## Effect of $CO_2$ Variation on Boiler Efficiency*

TO STUDY what effect variation of the $CO_2$ content of flue gases has on superheat some tests were conducted in which the flue-gas losses were calculated from the test data and the other losses determined by averaging a number of heat balances of evaporative tests conducted on the boiler. The loss due to "steam formed by burning hydrogen" was taken at 5.84 per cent and the loss due to "unconsumed hydrogen, radiation and unaccounted for" as 6 per cent.

These observations were made in an oil-fired 6,000-sq. ft. Babcock & Wilcox boiler with a double-deck Babcock & Wilcox superheater. The arrangement of the furnace was of the conventional "back shot" type with standard baffling.

The variation in $CO_2$ was procured by first obtaining the desired rating with good combustion, burners being carefully adjusted to get uniform flame from each, and then increasing the amount of draft, thereby lowering the $CO_2$, all other conditions remaining constant. In this manner good combustion was obtained throughout the test, the decrease in $CO_2$ being due to excess air only.

Steam temperature was measured with a chemical thermometer in a well with a mercury bath scaled for 3-in. immersion. Rating was determined by a flow meter permanently connected to boiler; $CO_2$, CO and O were determined with standard Orsat apparatus. There was no CO present in any of the tests made. All gages, meters, etc., were carefully calibrated and checked for accuracy before test. The steam pressure during the test averaged 210 lb. per square inch with the barometer 29.7 in.

Fig. 1 was constructed from the test data. The curves as drawn and marked for 75 per cent, 125 per cent and 175 per cent ratings are not, strictly speaking, constant-rating curves, but represent only the ratings at which it was endeavored to operate. $CO_2$ curves were constructed as shown in Fig. 2 from the average values given in Fig. 1 and show the amount of superheat to be expected with variations of $CO_2$. A further series of observations was made to obtain data from which heat balances could be calculated to give the efficiency curves shown in Fig. 2. Fig. 2 can be read in several different ways. It provides a means of determining whether the increase in superheat due to low $CO_2$ and poor combustion, which is partly overcome by the increase in efficiency of machines using the steam, is justified.

For an example, assume a boiler rating of 145 per cent and 14 per cent $CO_2$. With these conditions the chart shows the efficiency to be 80 per cent. By lowering the $CO_2$ to approximately 12.8 per cent the boiler efficiency is lowered 1 per cent and the superheat is increased 9 deg. F. An increase of 12 deg. F. superheat effects a 1 per cent saving on a modern steam turbine. This would indicate that the high $CO_2$ has an advantage over the high superheat by one-quarter of 1 per cent. Taking a wider range and reducing the $CO_2$ from 14 per cent to 10 per cent, the boiler efficiency falls off 3.5 per cent and the superheat is increased 43

*Abstract of paper presented at the Southwest Geographic Division, N. E. L. A., convention at Oklahoma City, Okla., March 14-16, 1923.

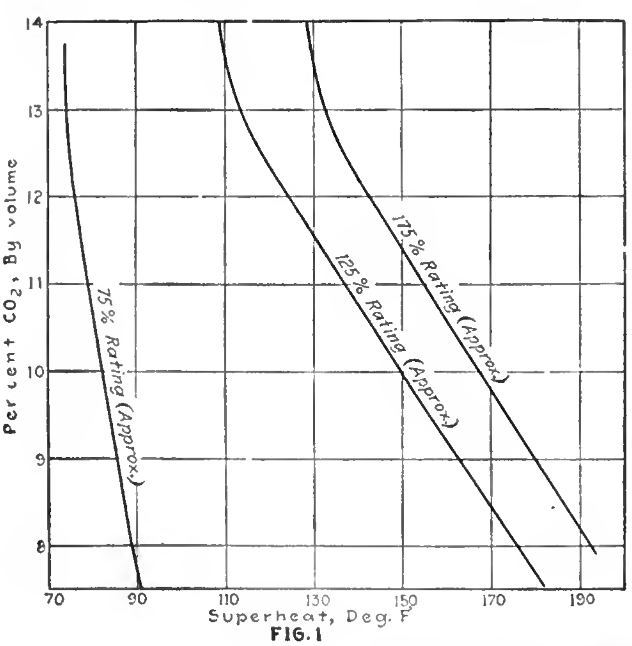


FIG. 1

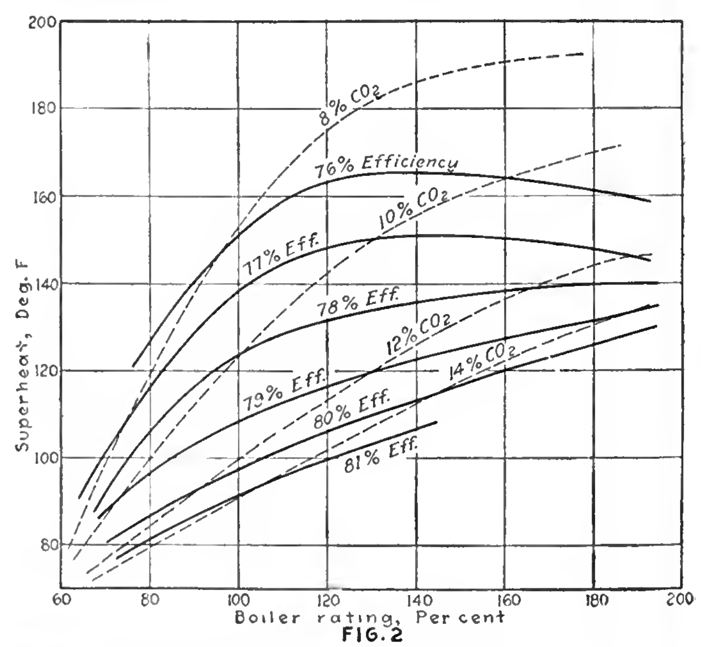

FIG. 2

FIG. 1—SUPERHEAT AND $CO_2$ RELATION AT VARIOUS RATINGS OF BOILER. FIG. 2—RELATION BETWEEN SUPERHEAT, $CO_2$ AND EFFICIENCY AT VARIOUS RATINGS

deg. F., which is equivalent to increased turbine efficiency of 3.5 per cent. This shows the loss in boiler efficiency to be exactly equal to the increased efficiency of the turbine effected by a higher superheat at this point.

The gain in efficiency due to high superheat is not so reliable as that obtained with good combustion in the boiler and high $CO_2$. Turbines will not produce this 1 per cent saving on light or heavy loads, and it is doubtful how many of them will produce it under normal load. Therefore, as such an extreme drop in the $CO_2$ is required to equal or surpass the saving due to high superheat, it is concluded that it would be advisable to maintain the maximum $CO_2$, keep the superheaters clean and let the superheat come where it will.

W. P. CREWS.

## Interruptions to Service Classified as to Cause

FOR the purpose of making a study of the causes of interruptions to service on its transmission and distribution lines and in its substations, the Southern California Edison Company makes out a monthly report classifying interruptions with respect to cause and to voltage of the line on which the trouble occurred. The report for the month of December, 1922, is shown herewith. The use of such a summary is of considerable value in analyzing the sources of trouble which cause interruptions on the system in order that steps may be taken to cut down these failures. The report is prepared by the load dispatcher from his operating records, and copies are sent to the manager of operation and the protection engineer.

TRANSMISSION-LINE INTERRUPTIONS CLASSIFIED WITH RESPECT TO CAUSE AND VOLTAGE OF LINES

| | Number of Interruptions Voltage of Lines in Kv. | | | | | |
|---|---|---|---|---|---|---|
| Cause of Trouble | 10 | 15 | 30 | 50 | 60 | 150 |
| Unknown | 38 | 8 | | 2 | 6 | |
| Fires | | | | | | |
| Insulator failure | 10 | 6 | 2 | 2 | 3 | |
| Lightning | | | | | | |
| Flashovers | | | | | 5 | 2 |
| Accidents | | | | | | |
| Mistake in switching | | 3 | | | | |
| Oil-switch failure | | 2 | | | | |
| Failure of low-tension oil-switch to open, kicking out high-tension switch | 9 | | | | | |
| Switch trouble (mechanical) | 1 | | | | | |
| Switch trouble (control) | | | | | | |
| Pole broken by auto | 2 | 2 | | | 1 | |
| Pole raised into line | | | | | | |
| Pole burned off | 3 | 2 | | | | |
| Pole blown over | | | | | | |
| Wires blown together | | | | | | |
| Tree in line | 1 | 1 | | | | |
| Trouble on foreign lines | | 7 | | | 2 | |
| Birds | | | | | 3 | |
| Airplane hit line | | | | | | |
| Fuse holder grounded | | | | | | |
| Failure of consumer's transformer | 3 | 1 | | | | |
| Shorted by lineman | 1 | | | | | |
| Shorted by telephone line | | | | | | 1 |
| Shorted by house movers | 1 | | | | | |
| Circuit closed out of phase | 2 | | | | | |
| Lead melted out of lug | | 1 | | | | |
| Pothead failure | | 1 | | | | |
| Cable failure | | | | | | |
| Arrester trouble | 1 | | | | | |
| Jumper loop burned off | | 1 | | | 1 | |
| Total | 72 | 35 | 2 | 4 | 21 | 3 |

A word of explanation in connection with the report will make the nature of the trouble covered by some of the classifications clear. "Unknown" covers such conditions as where a switch on a transmission or distribution line "kicks out" and can be reclosed by hand with no repetition of the trouble, or where no evidence of a flashover can be found by a patrolman after going over the line. "Failure of low-tension oil switch to open, kicking out high-tension switch," covers cases where an oil switch of the voltage indicated fails to open and causes other switches to operate. "Trouble on foreign lines" refers to cases of trouble communicated to the company's system through interconnections with other power systems or to trouble arising on railway lines or distribution systems of municipalities supplied by the Edison company. The number of interruptions from insulator failures, as shown by the report, indicates that troubles from this cause are by no means confined to high-voltage lines on this system.

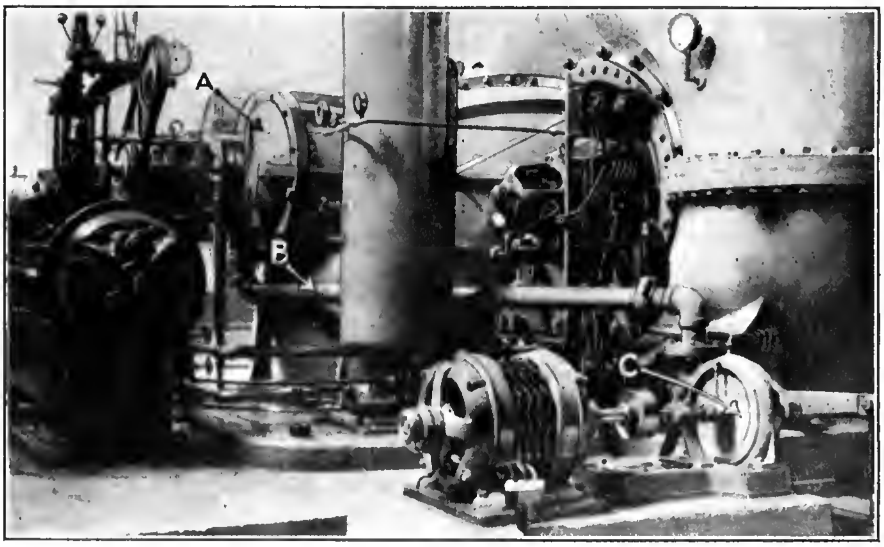
## Auxiliary Pump on Turbine Counteracts End Thrust

THE end thrust of horizontal single-discharge reaction turbines is toward the draft-tube side and is generally counteracted by some type of balancing piston. On a 2,000-hp. unit provided with a hydraulic thrust piston and renewable bronze wear rings it was found that the rings had to be renewed quite frequently when the machine was operated under full load for any length of time. This thrust piston is placed where the shaft leaves the draft tube, and the piston chambers were orginally supplied by a pipe direct from the turbine casing. There was thus the full turbine pressure on one side of the piston against the draft-tube vacuum on the other, tending to counteract the end thrust.



RING REPLACEMENTS ON REACTION TURBINE DECREASED BY INCREASING PRESSURE IN HYDRAULIC THRUST PISTON

To prevent the rapid wear of the renewable rings on the thrust piston, a small centrifugal pump was introduced into the pipe line from the turbine to the piston. This raised the pressure in the piston about 5 per cent above the turbine pressure, with the result that the turbine could be operated satisfactorily at full load and with no appreciable ring wear at the piston.

The arrangement that solved this difficulty is shown in the accompanying illustration, in which *A* is the hydraulic thrust position, *B* the pressure piping and *C* the centrifugal pump driven by a 10-hp. motor and connected by a flexible coupling.

## Instructions for Operating Evaporators

EVAPORATORS, by vaporizing and condensing raw river water, remove from the make-up water of a station all mud and foreign matter, which, if allowed to enter the boiler, would cause excessive scale formation on the tubes. It is not advisable to use superheated steam in evaporators on account of the priming of the first-effect shell caused by too rapid boiling or evaporation. Water is admitted to the live steam to reduce the superheat to zero or to saturated steam temperature.

The coils should be covered with water, as any portion of the coil being uncovered will not only reduce the capacity of the evaporator but will have the scale baked on it so hard that it cannot be removed by the usual "cracking down" process. When an evaporator is taken out of service, the coils should be covered with water to prevent the scale from drying on the coils. It is important that the high-pressure and low-pressure traps be properly vented since steam contains more or less air and non-condensable gases. Furthermore, if not vented, the coils will fill up with air, which will reduce the capacity. The following rules for putting an evaporator into service and for taking it out are part of the operating code of the Philadelphia Electric Company.

PUTTING AN EVAPORATOR INTO SERVICE

1. See that water supply lines and exhaust steam lines to the evaporator heater are in operating condition.
2. Start the evaporator feed pumps.
3. See that all blow-down valves are closed and that the vent on each shell is open.
4. Fill each shell to the running water level as indicated by the mark on the shell.
5. Open the vents on the traps on both high-pressure and low-pressure coils.
6. Open wide the vapor valve on the first effect.
7. Open the vapor valve on the second effect.
8. Open slowly the high-pressure steam valve to the first-effect coils, noting that the reducing valve maintains 200 lb. gage pressure.
9. Maintain 388 deg. steam temperature by adjusting the boiler-feed supply to the desuperheater.
10. See that the trap is functioning on the steam separator.
11. Close the vents on the shells when the steam appears.
12. Slowly build up pressure in the shell of the first effect to 57 lb. by increasing the live steam to the coils of the first effect until 200 lb. at 388 deg. F. is maintained at the entrance of the coils.

TAKING AN EVAPORATOR OUT OF SERVICE

1. Close the high-pressure steam valve to the first-effect coils.
2. Close the water line to the desuperheater.
3. See that the float valves shut off the water after evaporation stops.
4. Close the vapor valve on the second-effect shell.
5. Shut down the evaporator feed pump.

## Starting and Stopping Small Motors on Auxiliaries

CONTINUITY of service depends upon having all equipment ready for immediate service, and definite instructions for operating apparatus will very often prevent interruptions caused by carelessness. The following instructions for starting and shutting down small motors, while not complicated, should always be kept in mind by operators. They have been abstracted from the operating code of the Philadelphia Electric Company.

SYNCHRONOUS MOTORS—STARTING

1. Close the starting switch and note that the rotor turns over.
2. After the motor comes up to maximum speed on the starting switch, open the starting switch and immediately close the running switch.
3. After the motor comes up to maximum speed on the running switch, see that all the field resistance is cut in, close the field switch and adjust the field for the maximum armature current.

SHUTTING DOWN

1. Open the running switch.
2. Cut all field resistance in.
3. Open the field switch.

INDUCTION MOTORS STARTED BY COMPENSATOR—STARTING

1. See that the compensator handle is in the "off" position.
2. Close the motor main switch.
3. Throw the compensator handle to the starting position and note that the rotor turns over.
4. When the motor comes up to maximum speed on the starting position, throw the compensator handle to the running position.

SHUTTING DOWN

1. Open the motor main switch.
2. Return the compensator handle to the "off" position if it does not return automatically.

MOTORS STARTED FROM AUTOMATIC CONTROL PANEL—STARTING

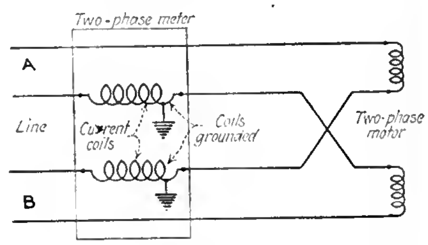
1. See that the controller is in the "off" position.
2. Close the motor main switch, if it is not already closed.
3. Throw the controller handle to the required running position.
4. Note that the motor comes up to the required speed.

SHUTTING DOWN

1. Throw the controller handle to the "off" position.
2. Open the motor main switch, unless other motors are fed by this switch.

## An Interesting Case of Two-Phase Meter Trouble

WHEN a two-phase meter supplying about 40 hp. of motors was tested in place the meter was found to be slow and did not respond to the usual adjustment. The tester arranged for a shutdown during the noon hour to replace the meter. After replacement the motors were tried and only one would start, the remainder appearing to receive single-phase current only. The new meter was removed and the meter loop connected through solidly. The single-phase condition still existed,



MOTORS OPERATED ON CROSS-PHASE CONNECTION BECAUSE BOTH CURRENT COILS OF METER WERE GROUNDED

although a lamp test showed both phases normal. The old meter was then replaced and all motors operated satisfactorily.

A later investigation disclosed the fact that both current windings of the old meter were solidly grounded to the case near the outlet, making one wire of each phase common. All but one of the motors were connected cross-phase, so that operation was possible only when the two wires passing through the current elements of the meter were tied together. Presumably the meter failure occurred prior to a recent rearrangement of motor wiring, and the electrican simply connected each phase of the motors across any pair of wires that had a difference of potential of 220 volts. This experience demonstrates the care that must be exercised when installing any equipment.

## Service Quickly Restored by Portable Substation

TO MINIMIZE the period of outage resulting from failures of power transformer installations on 6,600/2,200-volt lines and the expense of restoring service, especially when these emergency conditions occur after working hours, the Dayton (Ohio) Power & Light Company utilizes a portable transformer substation which can be hauled out to a job and placed in operation in a very short time. The use of this portable substation has enabled the company to change transformer banks up to 150-kva. capacity, replace bad transformers on existing banks and replace bad poles or timbers on transformer structures without interrupting the service to the customer. It is also useful for supplying power for temporary jobs of short duration where it is not deemed necessary to install a permanent structure.

The portable substation consists of three 50-kva., single-phase, 6,600/2,200-volt transformers banked in closed delta and mounted on a two-wheeled rubber-tired trailer. A definite idea of the substation may be obtained from the detailed plans and the illustrations shown herewith. The trailer is equipped with a rigid prop on the rear end and an adjustable prop on the front end which permits it to be maintained perfectly level when stationary, the weight of the transformers being so distributed that the entire structure is almost balanced. Each of the transformers is bolted to the substructure of the trailer by means of long through bolts extending down from the lid of the transformers, thus keeping them rigid at all times.

The transformers are completely housed in on all sides with a wooden housing extending from the bottom up to a point approximately 8 in. above the top of the transformers. This housing completely hides the transformers from view and also prevents any one standing on the ground from coming into contact with any of the primary or secondary leads.

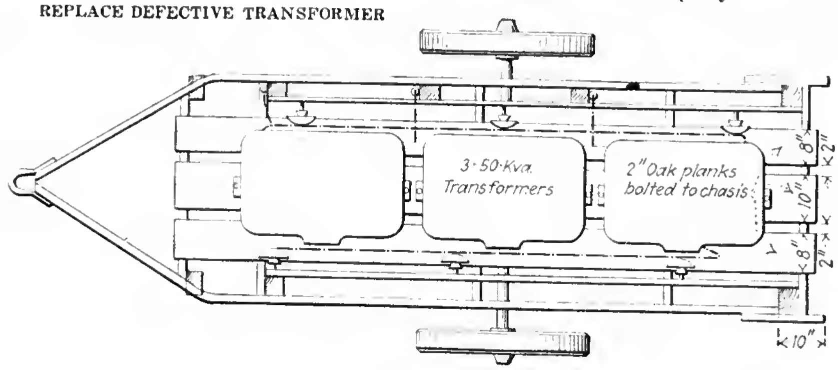
The incoming primary leads are supported on three 4-in. x 4-in. uprights spaced approximately 2½ ft. apart, which extend 15 ft. above the ground level and are fastened to the primary side of the transformer housing. The primary cut-outs are mounted on these uprights about 12 in. from the top and are so arranged as to be easily accessible.

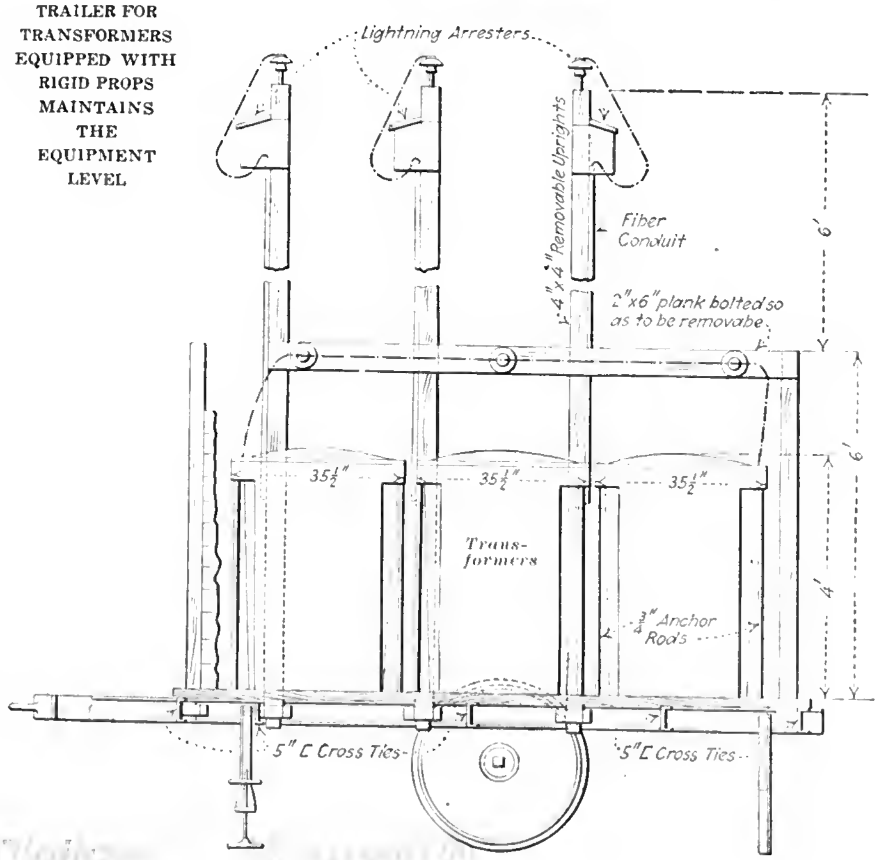
PORTABLE SUBSTATION CURTAILS EXPENSE OF WORKING LINEMEN OVERTIME TO REPLACE DEFECTIVE TRANSFORMER

A 5-kva. compensator has been installed and can be connected up to the secondary side of the transformer bank so as to supply 115-volt service for lighting if necessary. This compensator is only used when the transformer bank being changed is connected 230 volts on the secondary side and when the lighting is also supplied by the same transformers.

In keeping with the safety first policy of the company to warn the public of the proximity of high-tension wires, prominent danger signs are attached to the housing of the portable substation and are so placed as to be clearly legible and easily noticeable.

The use of the portable substation has enabled the company to cut down





TRAILER FOR TRANSFORMERS EQUIPPED WITH RIGID PROPS MAINTAINS THE EQUIPMENT LEVEL

the length of outages due to transformer failures during electric storms to a minimum and has also curtailed the expense of working its linemen overtime in order to replace defective transformers.

The company is contemplating a few changes in the design of the substation, however, one of the principal ones being the replacing of the two-wheel trailer with a four-wheel trailer. It has been found almost impossible in some instances to haul the substation right up to the source of trouble by means of a truck, and the four-wheel feature will permit the trailer to be pushed to the necessary location without the danger of upsetting the structure.

## Testing Distribution-Line Ground Conditions

As most companies ground all secondary distribution lines at the customers' services it is essential to have a rapid and accurate check to determine whether the proper wire is grounded. Very often when an operating company takes over small systems and connects them to its lines it is found that the distribution secondaries are not grounded. The writer had occasion to check the grounding conditions in a small system taken over by this company and wished to make a check that was rapid and at the same time accurate. This was accomplished by using the simple device of two lamps in series, with means of grounding the wire between the two lamps.

Two weatherproof sockets were connected in series to an ordinary attachment plug, and a lead 20 ft. in length was taken from between the two lamps. The writer and a lineman then started from the substation, following the primary line. As each transformer was reached the lineman would obtain the necessary data by climbing the pole. The attachment plug was then inserted in any lamp socket in the nearest house taking service from the transformer. Then the wire connecting the two lamps in series would be grounded at the nearest source. If the transformer was properly grounded, one lamp would go out while the other would come up to normal voltage. In case of a three-wire service where an outside wire had been grounded by error, all services taken from the grounded side and the neutral would test as above, while a service taken from the neutral and ungrounded side would show double voltage to ground. In case of three-wire services care was taken to get a test from services taken from each outside-line wire and neutral.

When the transformer was not grounded at all, the two lights would burn at half voltage and no change in brilliancy would be made when grounding the test lead. In the case of several transformers that had been grounded to pipes there was a slight dimming of one light while the other would brighten to a small degree, showing that the grounding was insufficient.

Forty transformers were tested in one day, and it was found that less than one-half of them were grounded satisfactorily. Four had an outside wire of the three-wire, 220-volt service grounded, instead of a neutral, while others were entirely clear of grounds.

## Cost of Installing Single Lightning Arrester

An itemized table of the cost of purchasing and installing a single 1,000-3,000-volt lightning arrester in a substation about two miles from the generating plant of a Massachusetts central station is given here. The labor and material charges were almost equally divided. The tabulation is suggestive because of the completeness with which minor items in the supply line are covered.

INSTALLATION COST OF LIGHTNING ARRESTER

| | |
|---|---|
| One 1,000/3,000-volt lightning arrester, complete | $397.00 |
| Freight | 7.99 |
| Angle iron | 13.40 |
| Channel iron | 2.60 |
| Paint, 3 gal., at $2.54 | 7.62 |
| Pipe, bushings, etc. | 1.33 |
| Fifty-four machine bolts, assorted. | 0.85 |
| Four rolls tape, at $0.61 | 2.44 |
| One 5-gal. can "Justrite" | 8.50 |
| Gasoline, 18 gal. | 4.60 |
| No. 227 compound | 1.22 |
| Waste | 0.59 |
| Expansion screws, ½-in. | 0.79 |
| Carriage bolts | 0.20 |
| No. 4/0 copper sleeves | 0.52 |
| String solder | 1.36 |
| Solder paste | 0.10 |
| No. 2 stranded bare wire | 1.07 |
| One weatherproof socket | 0.23 |
| Two rolls "Marlin," at $0.345 | 0.69 |
| Lag screws | 0.18 |
| Payroll, labor | 426.34 |
| Total | $879.62 |

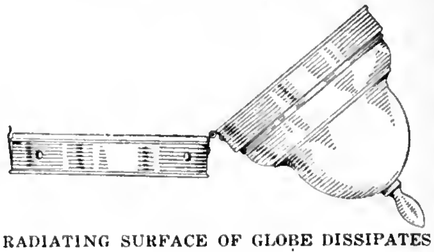
## Modified Ventilators for Street Lamps

The question of just how much ventilation is necessary for the economical operation of single-light units of 400 cp. to 600 cp. for street lighting has been the subject of considerable discussion, and perhaps a statement of the experience of the writer will be of interest. The first trouble was experienced after the initial installation of forty 400-cp., 6.6-amp. single-light standards made about eight years ago, using the Macbeth-Evans Monax globes and copper ventilator, which is similar in design with all others, the hot air being expelled at the top through small holes under a protecting cap. In the north country we have some severe snowstorms accompanied by high winds, and we found that after such a storm, occurring in the daytime, the snow would enter through the ventilator and lodge on the top of the lamp. When the current was turned on to the circuit the lamps would explode one after another.



RADIATING SURFACE OF GLOBE DISSIPATES HEAT OF STREET LAMP

Investigation finally brought the remedy. All of the ventilators were brought into the shop and a circular piece of tin was soldered into them just where the top of the globe came. This tin was then covered with a heavy piece of cloth so that when put on the globe and screwed down all ventilation through it was cut off. We operated forty of the posts through one entire winter without a failure due to snow, and as fast as we installed posts thereafter we used the same method until last year, when the writer designed a "ventilator," or helmet which does not ventilate. We are now operating 170 400-cp., 6.6-amp. single-post lamps equipped as stated above and have had no failures due to snow entering globes. Tests have shown that the globe has radiating surface enough to take care of the heat generated by the lamp, our record being two and one-half renewals per post per year, burning 4,000 hours.

## Why Public Utilities Should Advertise

### Of Three Billion Dollars Gross Income the Four Major Utilities Spend but One-fourth of 1 per Cent for Advertising, Whereas They Should Appropriate $60,000,000 Annually

By W. P. Strandborg
President Public Utilities Advertising Association, Portland, Ore.

In a great many public utility companies the underlying reason why the executives have not been "sold" on the idea of the value of advertising is because their training, experience and habitual viewpoint have not brought advertising clearly above their horizon. If they have glimpsed its meaning at all, it has generally been that it deals with intangibles to a greater or less degree —and intangibles are something that technical engineers, lawyers and unimaginative operatives and managers have had little sympathy with or understanding of.

But once these executives have been "shown" what advertising has done and can do, when given an honest and thorough test, a great majority of them give it the recognition its importance deserves.

The writer has come in contact with many such cases, and that is why he has set down a few of the reasons why public utilities should advertise—so that our members, if they feel that their own companies are not giving the proper prominence to advertising, may use some of these suggestions as the basis for "selling the idea to the boss."

Public utilities should advertise because:

1. We have a seventeen-billion-dollar investment to protect.

2. This gigantic investment is subject to attack and harassment by all sorts of regulatory and legislative bodies, by the general public and the newspapers to a greater extent than any other large and legitimate business in the country.

3. We do $3,000,000,000 worth of business a year, and because intelligent advertising will stimulate it to greater growth.

4. We are far in the rear of every other modern business in advertising.

5. We need the greater good will of our 33,000,000 customers.

6. Our business comes into more intimate daily contact with more people than any other line of business in the world.

7. Our business, which is so essential to the comfort and well-being of the people, is highly technical, and the public does not understand it.

8. Our problems are the problems of the people, and we need their sympathetic understanding and support.

9. The people will be fair when they do understand all the facts, and systematic advertising is the most effective way to tell our story and give the people the facts.

10. Our exclusive business is salesmanship in its broadest application, and every form of salesmanship needs the fifty-fifty push and punch of advertising.

11. The selling of public service—essential and indispensable public service, if you please—is known, by experience and test, to respond as rapidly and in as great a measure to judicious advertising as the selling of any legitimate merchandisable commodity.

12. Many of our companies sell securities just exactly as investment houses do, and where would investment houses be if they didn't advertise?

13. Many of our companies sell merchandise exactly as department stores and specialty shops do—institutions whose advertising appropriations average from 2 to 7 or more per cent of their gross each year.

14. The demand for any worthy product—service, security or commodity—can be created and stimulated by means of advertising.

15. The greater the demand for any product, the less will be the ratio of production cost, with proportionately greater economy of operation.

16. It is the specific function of advertising to create consumer demand and consumer preference.

17. Truthful, sincere, interesting and believable advertising is a recognized asset in modern business.

18. Advertising will bring the full benefits of the merit of our product.

19. Advertising is the most inexpensive motive power that our industry or any industry can buy today.

20. The great "buyers' strike" following the world war proved that more and better advertising meant more and better business and more and better good will.

21. The place of advertising in the present economic system is thoroughly well established.

22. Business exists, in the last analysis, in the minds of its customers.

23. While you may supply the actual needs of the public without advertising, the actual needs are but a fraction of the demand that can be created, and advertising is a prime mover in creating this demand.

24. Public utility commissions in many states have recognized advertising as a legitimate operating expense, both in the creation of good will and in business building, thereby nullifying the somewhat widespread popular criticism that advertising by public utilities is a needless extravagance.

25. A public utility that advertises consistently finds it easier to finance its requirements than one which does not advertise. Bankers generally look upon a good advertiser as a good borrower, and prospective borrowers are frequently asked, "What is your advertising appropriation?"

26. Experience shows that public utilities which have adopted definite advertising programs on a budget basis have never abandoned this policy, but, on the other hand, have shown a tendency to expand their advertising appropriations year by year.

27. Advertising, properly used, will increase the turnover for utilities just as it does in other lines of business.

This list of "becauses" is by no means complete. It could probably be elaborated to twice the number given, and even among some of those set down there is some overlapping, yet the main thought is to show public utility companies that they have an abundant reason for giving advertising a fair trial and little, if any, reason for not doing so.

When it is considered that a mighty industry with a combined capitalization of more than $17,000,000,000, with a yearly gross business exceeding $3,000,000,000, deals in intimate daily contract relations with an aggregate of more than 33,000,000 customers, the importance of advertising to this industry need not be further emphasized.

There is expended in the United States each year for advertising a total of something in excess of $1,400,000,000, and of this amount the four major utilities—light and power companies, electric railways, gas companies and telephone companies—are using only about $7,500,000. It does look as if some of us have not acquired a very keen sense of business proportion.

Based on a 2 per cent minimum of annual gross business, the four utilities mentioned should be spending around $60,000,000 instead of $7,500,000. Instead of the 2 per cent minimum, the utilities are trailing along with an average of approximately one-fourth of 1 per cent. Five years ago, the amount was probably less than half what it is now.

## Central Station Boosts Dealers' Business

TEN illuminated billboards inscribed "The Electrical Dealers of Vancouver," similar to the one shown here, are paid for and maintained by the British Columbia Electric Railway Company of Vancouver, B. C. Although the company does a merchandising business itself, the billboards are maintained to help the dealers and to let the public know that there are other electrical interests in the city besides the central-station company. The company believes that in any event the sale of appliances results in the greater use of electrical energy, which will be reflected in increased revenue.

TYPE OF BILLBOARD MAINTAINED BY CENTRAL-STATION COMPANY

# Savings to Customer of Good Power Factor

### Increases Speed of Production—Reduces Energy Consumption—Increases Efficiency and Improves Operating Characteristics of Machines

ON MAY 14, before the Philadelphia Section of the A. I. E. E., C. J. Russell and J. F. Gaskill of the Philadelphia Electric Company presented a valuable paper entitled "Power Factor—Its Relation to Industrial Plants." Mr. Gaskill, who read the paper, pointed out that the attitude of the central-station companies on the much-discussed question of power factor was to stimulate the customer to purchase and install power-factor corrective equipment and that the companies have done this very largely by incorporating power-factor clauses in their rate schedules. The result has been that frequently attention has been focused only on the economics of rates and there has been a lack of fundamental attempts to convince the customer of the other benefits of a good power factor.

There are many conditions in industrial plants that may make low power factor a source of expense to the customer far in excess of the amount of the rate discount. Any power-factor correction must be based on an analysis of the plant and its operation, and a fundamental requirement is that the plant should be properly motored. This means that the type, rating and grouping of motors must be suited to the work and to taking the utmost advantage of corrective equipment. Many times, too, the copper sizes should be readjusted to the actual load conditions. After making this analysis the power-factor corrective equipment should make an annual saving of at least 20 per cent on the first cost to justify its installation. An outstanding example of this method was found in a factory having a 30-kva. demand and 60 per cent power factor before correction was applied. After rearrangement of motoring the demand was reduced to 20 kva. and the power factor raised to 77 per cent with only 8.5 kva. of corrective equipment. In another case a 33⅓ per cent power factor was raised to 82.5 per cent by using static condensers.

A great advantage to the customer frequently not pointed out is the fact that a good power factor lowers line losses, improves voltage regulation, and consequently machine operation, and raises the efficiency of the machines. These savings are often appreciable. For example, in a hosiery factory for thirteen weeks before correction was applied the energy consumption per unit of product was 0.895 kw.-hr., and for twelve weeks after correction it was only 0.553 kw.-hr. This gave a saving of about 30 per cent in consumption of energy in addition to power-factor improvements. In another case the load was 54.7 kw. at 59.1 per cent power factor, and 63.5 kva. correction was needed, but after rearranging the motors, only two of which were replaced, a power factor of 92.1 per cent was obtained with 30 kva. corrective equipment.

In order to obtain these results—and in many installations such results cannot be obtained—an analysis of the installation and the use of graphic-meter studies of load cycles of the individual motors is essential before attempting correction. Motors, regardless of make, often differ in characteristics as regards the amount of magnetizing current, and ordinary commercial tests made by

the manufacturers will not detect this condition. Therefore it is necessary to take duty-cycle curves on the machines *in situ* and to study the requirements of the task the motor performs.

Power-factor correction at the source is best because it decreases the energy bill of the consumer by reducing losses and demand, decreases the energy loss and voltage drop in the service circuits, and increases the speed of production by maintaining better and more uniform voltage regulation. With source correction the use of few large-size units saves on investment costs for corrective equipment, but where many small motors are used group correction is best applied. From a load-characteristic standpoint there is the non-fluctuating, unvarying load such as electrolytic loads, in which indicating meters only are necessary for analysis. For the intermittent load, such as woodworking machines and machine tools, a graphic-chart study is best, and for rapidly fluctuating loads, either intermittent or steady, flywheels often prove useful and can be applied intelligently by using graphic charts.

After proper metering has been installed the next question is the type of corrective equipment to use. All features of the installation must be studied. The ideal method is to install equipment carrying load current. Practically the load may vary, and corrective equipment is adjusted for the no-load condition, after which a fairly good power factor can be maintained over the complete load range. Economic considerations dictate the amount of corrective kva. to use. Synchronous motors should be considered, in general, for the replacement of induction motors on loads of 50 hp. and over. The synchronous condenser is a bulk corrective device and enters into consideration for loads of 900 kw. and over on 2,200-volt circuits. For these loads it competes with the static condenser. Group correction with static condensers offers good possibilities where there must be no cessation of production and where a large number of small motors are grouped.

Correction at the motor terminals is not well suited for loads of low diversity or where small machines are used, and in these cases group correction is dictated.

The static condenser has operated very satisfactorily on the lines of the Philadelphia Electric Company and has given no indication of bad features due to harmonics or resonance effects. In closing, the author again accented the point that the consumer gets a number of advantages from operation with a good power factor besides the rate discount.

D. E. Drake, in discussing the paper, said that in general a great change could be made in demand without great change in energy consumption. He cited an example on a 20-hp. motor where the use of a type with 10 per cent slip as compared with 2.5 per cent slip changed the demand 20 per cent with only 5 per cent change in energy consumption. M. E. Skinner said the importance of power-factor correction was very evident and that steps should be taken to secure it. He also discussed power-factor rate clauses and proposed using both a penalty and a bonus. The manufacturers might, he thought, do something in the way of getting better designs of machines from the power-factor standpoint. L. W. W. Morrow pointed out that the commercial application of power-factor correction involves the supervision of customers' equipment or the use of complicated rate and metering systems.

## Worcester Appliance Sales a Third Above Last Year

THE manager of the appliance department of the Worcester (Mass.) Electric Light Company, O. R. Underhill, reports that sales for the first quarter of 1923 averaged $2,194 per week against $1,610 for 1922 and that the estimated revenue from these sales in energy consumed is $4,930 per year. Merchandising conditions are also better than those of 1921 by about the foregoing margin. Among the items sold in the first quarter of this year are 330 flatirons, 106 vacuum cleaners, 106 portable lamps, 90 two-compartment fireless cookers, 78 washing machines, 39 heating pads, 39 toasters, 37 curling irons, 31 heaters, 23 fireless cookers of a different type from the above, 18 hot plates, 12 percolators and 10 waffle irons. During the past few months the company has authorized the use of more space for appliance demonstration on the main floor of its general offices and has paid increasing attention to effective window displays. A carefully prepared series of articles with an engineering "slant" on home electrification by George M. Hardy, general superintendent of the company, has been running in the company paper, the *Live Wire*, and these have aroused considerable interest among employees and outside readers.

## Ranges as Income Bringers

THE electric range and the electric water heater, like the automobile in transportation, are coming to fill an increasingly important place in the kitchens of the average home. The accompanying table is given to show what the electric range and water heater mean to the central station in yearly and monthly revenue. In compiling this table an electric water heater is rated the same as an electric range, and where both are used they are served through one meter.

The outstanding feature about the revenue derived from range consumers is the fact that, in spite of lowered rates, the income per month per range has increased. In the year 1921 the income per range increased almost 20 per cent in the face of approximately 30 per cent reduction in rates for this service. In 1922 there was a still further increase in income from each range with a 10 per cent reduction in the cost of energy to the consumer. The reason for this increase in revenue from ranges is not hard to explain. When an electric range is placed in the kitchen it soon proves itself to be a paying investment. It saves time, food and labor, protects the family health, and with the later automatic types of ranges has in some cases eliminated the necessity of a servant.

All of these factors are but the entering wedge for a completely

SOUTHERN CALIFORNIA EDISON COMPANY'S REVENUE FROM ELECTRIC RANGES AND WATER HEATERS
(1919 to 1922 inclusive)

| Year | Number of Ranges | Number of Water Heaters | Total | Total Yearly Revenue | Yearly Revenue per Range | Monthly Revenue per Range |
|---|---|---|---|---|---|---|
| 1919 | 1,689 | 663 | 2,352 | $89,811.74 | $38.19 | $3 18 |
| 1920 | 2,015 | 835 | 2,850 | 139,394.96 | 47.00 | 3.91 |
| 1921 | 2,549 | 652 | 3,201 | 178,729.70 | 55 80 | 4 65 |
| 1922 | 3,084 | 757 | 3,841 | 221,551.48 | 57 65 | 4 80 |

equipped electrical home—first one appliance and then another follows the range. Probably the first is the electric water heater, then the dish washer, air heater, mangle, toaster, percolator and so forth.

It is these additional electrical servants that are increasing the income from each range user. After installing a range a great many consumers have begun to heat their homes with electricity, and on the ranches electric incubators and brooders have been added.

Fifteen hundred to two thousand electric ranges and five hundred to eight hundred water heaters will be connected to the lines of the company during 1923.

## Vacuum Cleaner Show Brings Many Sales

ONE of the most successful of the New York Edison Company's series of appliance shows which have been held in its Irving Place showroom this spring was the vacuum cleaner exhibit from May 14 to 19. At this show twenty-eight different cleaners were displayed, and the manufacturers and dealers who participated in the exhibit expressed themselves as highly pleased with the results. Attendance at the show was exceptionally good, and 107 cleaners were sold from demonstrations on the floor.

The vacuum cleaner show was the sixth of the series which have been staged by the Edison company since the first of the year. The seventh and last of the shows will be the electric vehicle exhibit, June 4 to 9, N. E. L. A. convention week, and upon this special effort is being exerted to make it of particular interest to visiting central-station men.

## Utility Suspends Stock Sale to Help Another Industry

THE action of the San Joaquin Light & Power Corporation in suspending stock sales for a period of thirty days so as not to interfere in any way with the refinancing of the Sun Maid Raisin Growers' Association exemplifies the interest a power company should take in the community it serves. The company's campaign to sell $2,000,000 in prior preferred stock started on March 15 and was well under way when it became evident that the drive of the Raisin Growers' Association would require the undivided attention of every investor in the San Joaquin Valley. The raisin industry is of vital importance in the territory served by the power company, and accordingly a postponement in the sale of the utility's stock was declared so that the raisin men could have the right-of-way.

The following letter addressed to district managers and department heads of the San Joaquin Light & Power Corporation by General Manager A. Emory Wishon shows the company's policy of co-operation with other industries in its territory:

We have just started a campaign to sell our prior preferred stock to the public through the agency of our employees. Quotas have been allotted and the whole set-up has been based on the spirit of competition.

Just at this time the Sun Maid Raisin Growers are arranging for a drive to sell $2,500,000 in stock throughout the San Joaquin Valley. The stability of the raisin industry is the most vital and serious subject that has ever confronted this great valley. The Sun Maid stock must be sold. Our own drive will mean little to us if the raisin industry is not maintained on a strong, well-financed basis. Our drive must be regarded of secondary importance for the time being. We deem it highly advisable at this time to delay our own campaign until April 26 (Raisin Day), the date on which the Sun-Maid drive terminates.

On April 27 the sale of San Joaquin prior preferred stock will again be opened on the same basis as originally outlined. This delay will mean additional effort on the part of all of us during the remainder of the year; but I know you feel as I do that we must do everything possible during the next month to see that the Raisin Growers' effort at refinancing is successful.

## What Other Companies Are Doing

**Providence, R. I.**—On March 1 the Narragansett Electric Lighting Company's lighting division faced a deficit of 30 per cent in campaign meters as compared with the total set up during the corresponding period of 1922. A "nothing down" house-wiring offer was therefore instituted, the first payment being due thirty days after signature of contract and the balance monthly with the same time limit as in other offers. Business immediately picked up, March showing 506 meters added and April 1,045 meters, or more than double the previous maximum monthly record. In two months, says F. A. Gallagher, Jr., manager of the division, the 30 per cent deficit was changed to a gain of 49 per cent over the same period last year.

**Indianapolis, Ind.**—On May 12 the Electrical Development Association of Indianapolis opened a nine-room electric home in this city for a one-week display to the public. For the promotion of the home a budget of $4,000 was appropriated by the electrical interests of Indianapolis, of which $3,700 was spent for publicity.

**Manchester, N. H.**—To obtain the needed increase in space for its general offices and appliance sales department, the Manchester Traction, Light & Power Company has announced the plans for a new office building to be erected in the shopping center of the city.

**Fresno, Cal.**—Work on the ten-story office building of the San Joaquin Light & Power Corporation is progressing rapidly, and it is expected it will be completed and ready for occupancy by Nov. 1 of this year. A large electric sign will be placed on the roof of the building, and special attention is being given to the lighting and electrical installation in the building. A radio-telephone set for broadcasting programs and load dispatching will be a feature of the company's new quarters.

ONE AISLE OF VACUUM-CLEANER EXHIBIT AT NEW YORK EDISON SHOWROOM

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Generation, Control, Switching and Protection

*Dynamic Braking Characteristics of Induction Motors.*—T. P. KIRKPATRICK.—Dynamic braking is obtained by disconnecting the motor from the power line and applying direct current to one or more phases of one member, usually the stator, while the windings of the other member are closed through a resistor. Then when the rotor turns the conductor cuts the magnetic field, inducing voltage and current with the resulting torque. The method of predetermining the performance of a motor under these conditions is described. The torque obtainable is equal to about 150 per cent of full-load torque. While dynamic braking is not adapted to all braking requirements, there are many applications where its advantages merit careful consideration.—*Electric Journal*, April, 1923.

*Problems in High-Speed Alternators and Their Solution*—J. ROSEN.—The author presents in a concise form some of the more interesting problems encountered and the methods adopted to solve them. Among the subjects covered are the history and failures of turbo-alternators, mechanical construction of rotors and caps supporting the coil ends, stator windings and insulation, stator slots, ventilation and cooling, exciter instability, eddy currents in rotor and several oscillographic tests. —*Journal of the Institution of (British) Electrical Engineers*, April, 1923.

## Hydro-Electric Development and Steam Equipment

*Preliminary Developments on a Hydro-Electric Project.*—H. K. FOX.—On the north and west forks of the Kings River in California the San Joaquin Light & Power Corporation has started work on the first unit in a chain of hydro-electric developments that will ultimately produce more than 300,000 hp. The main features of the development discussed are the four storage reservoirs, ten diversion dams, 34 miles of tunnels and conduits and seven proposed power plants.—*Engineering News-Record*, April 19, 1923.

*Steel-Mill Power Costs Reduced by Heating Feed Water.*—L. HELANDER.—A significant reduction in fuel consumption can be obtained by using multiple-stage condenser heaters and bleeding the main turbine. This involves replacing the common method of the feed-water heating in an open heater by a series of closed heaters. The author demonstrates the merits of the various methods of heating the feed water and of driving the auxiliaries by establishing heat balancers for an assumed steel plant having steam-driven turbo-blowers, steam turbine generators and completely electrified mill drive. He presents a table of comparative fuel consumption and power data for various methods of driving auxiliaries and heating the boiler-feed water of a steel plant.—*Iron Age*, April 12, 1923.

*High-Temperature and High-Pressure Steam Lines.*—B. N. BROIDO.—An abstract of this paper, presented at the annual meeting of the A. S. M. E., may be found in the ELECTRICAL WORLD for Dec. 9, 1922, page 1291.—*Mechanical Engineering*, May, 1923.

## Transmission, Substations and Distribution

*Calculation of Direct and Alternating Current Networks.*—F. T. CHAPMAN.—The author discusses the "break" or "cutting-point" method for calculating direct-current networks and introduces a complementary theorem to show the usefulness of these methods for alternating-current circuits.—*Electrical Review*, March 30, 1923.

*Fatigue of High-Voltage Cables.*—M. KLEIN.—Basing his observations upon a large series of carefully conducted tests on specially made paper-insulated high-voltage cables, the author describes a heretofore unobserved phenomenon of fatigue observed on the cable. One of two equal lengths of cable was subjected to the standard voltage test, the other was intermittently tested with a considerably higher tension. Short lengths of these two cables were then electrically punctured. The higher-stressed cable broke down at 10 per cent lower values than the normally stressed cable. Further overvoltage tests lessened the dielectric strength of the cable to 13 per cent below that of the normally tested cable. Five weeks later the same cables were tested again, without previous stressing, and it was found that they both now showed the same dielectric strength. The author assumes from this that the previous decrease of the puncture voltage must have been due to a temporary fatigue effect from which the cable recovered. That the heating of the cable due to the overvoltage stress could not have been responsible for the lessened dielectric strength was demonstrated by check tests in which the cable was purposely heated before being tested.—*Elektrotechnische Zeitschrift*, March 15, 1923.

*Inductive Interference Between High-Voltage and Low-Voltage Lines.*—R. RÜDENBERG.—Much has been written on this subject, but all calculations were based upon the partial capacities of the two lines under consideration. This paper shows a direct and much more convenient method by taking into account the electric fields formed around the wires. Formulas are developed for single, two-phase and three-phase lines, with concrete examples for each case. An important part of the article is devoted to conditions on three-phase lines with a ground on one of the conductors.—*Bulletin de l'Association Suisse des Electriciens*, March, 1923.

## Units, Measurements and Instruments

*Directions for the Study of Pressboard for Electrical Insulating Purposes.*—The report of the British Electrical and Allied Industries Research Association on pressboard for electrical insulating purposes. It contains definitions, terminology and classification of pressboard, tests and a method of ascertaining the electrical strength of pressboard when subjected to long application of alternating-current stress. The specific tests described include the following: tensile strength and extension, compression strength, shearing or tearing strength, cohesion between layers, flexibility, electric strength, shrinkage and swelling, freedom from chemical reaction, conducting particles and pinholes, effect of oils, water absorption and determination of thickness and density.—*Journal of the Institution of (British) Electrical Engineers*, April 1923.

*Control of Boilers by Temperature and Draft Measurements.*—J. B. C. KERSHAW.—The author describes various types of draft gages and temperature indicators. He discusses the proper location both for induced-draft and forced-draft systems and points out the best location for draft gages and temperature indicators.—*Engineer*, April 27, 1923.

## Illumination

*Electrifying the Garment Industries.*—The methods used by a successful electrical contractor in wiring lofts for the garment industries are described. The description tells the requirements of each department and how these requirements are met both in the correct planning of the machines and the installation and selection of the proper electrical and lighting equipment. A comprehensive table of dimensions, outlets and lighting units used in a typical garment loft is given.—*Electrical Record*, April, 1923.

## Heat Applications and Material Handling

*Transformer to Heat Wheel Tires.*—T. PAUSERT.—Locomotive and car-wheel tires are fastened to the wheel body by heat shrinking. The heating of the tire is done either with a charcoal fire or with a number of gas torches. It requires 3 cu.m. to 6 cu.m. of gas to heat one tire of a diameter of 104 m. to 1.50 m. Considerable difficulty is encountered in heating the tire uniformly by these methods and in controlling the heating properly, and a new electric induction type of heater

has been developed for this purpose, based upon the same principle as an induction furnace. A two-legged transformer core with the primary winding placed around the lower yoke has an easily removable upper yoke, the magnetic joint being of the butt type. With the yoke removed, the tire is placed over one of the upright transformer legs, the yoke is closed, and the primary winding is energized. The tire represents the short-circuited secondary winding and will soon come to the necessary red heat. Two models are being manufactured for tires up to 0.80 m. and up to 1.90 m. diameter respectively. To heat an 0.80 m. diameter tire, 25 kva. at 65 per cent power factor is required for twenty-five minutes. Primary winding taps permit heat regulation within wide limits.—*Revue Générale de l'Electricité*, March 24, 1923.

## Motors and Control

*Starting of Three-Phase Induction Motor with Cage Rotor.*—T. HASEGAWA. — In the three-phase squirrel-cage induction motor the problem of increasing the starting torque and of suppressing the heavy starting current have been the most troublesome. The author classifies and tabulates the various methods that have been developed along this line.—*Journal Institute of Electrical Engineers of Japan*, March, 1923.

*Brush-Shifting Polyphase Motors.*—R. A. JONES and F. A. ANNETT.—For loads requiring speed adjustments the polyphase brush-shifting alternating-current motor is finding wide application. In this article the fundamentals governing the operation of this type of motor are explained by comparing its action with that of a direct-current series motor.—*Power*, April 17, 1923.

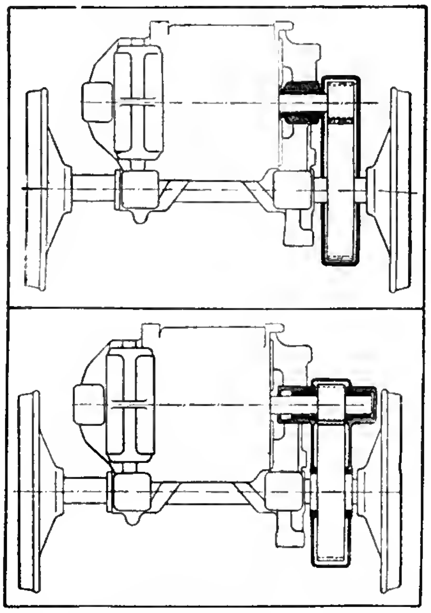
## Electrophysics, Electrochemistry and Batteries

*Reactions of the Lead Storage Battery.*—M. KNOBEL.—After a short theoretical discussion of the lead storage batteries, the results of the author's investigations are given. These support the evidence in favor of the Gladstone and Tribe theory of reactions in the lead storage batteries. The claim of Fery that only one mol of sulphuric acid is used per two faradays on discharge is not supported, which tends to disprove Fery's theory.—*Paper Presented Before American Electrochemical Society*, New York, May 3-5, 1923.

*Oscillations Produced by Means of a Tungar Rectifier.*—Y. WATANABE.—The author treats of the relation between oscillation and the heating condition of the filament of the tungar rectifier, which forms the cathode of the arc. When the filament current is comparatively small oscillating currents of relatively high audio-frequency are produced, traversing the condenser connected across the terminals of the tungar bulb. This oscillation may be considered to be due to an ionic oscillation of negative ions in the arc. When the filament current is increased an intermittent current is produced in the condenser circuit, which is of low frequency. This phenomenon was oscillographically observed by Hull's arrangement for rectification with the kenotron.—*Journal Institute of Electrical Engineers of Japan*, April, 1923.

## Traction

*Double Bearing for Railway Motors.* —M. KAMMERER.—The author suggests increasing the life of the gears by abandoning the traditional flying pinion and that a bearing on either side of the



PINION OF DRIVING MOTOR PLACED BETWEEN DOUBLE BEARING

pinion be used instead. As these two bearings can be each only half as long as the previously used single bearing, it should not be difficult to find room for this construction, as will be seen from the accompanying figure. With such a bearing construction, a pressure on the teeth not exceeding 600 kg., and lubrication with oil rather than with heavy grease, the life of these gears will be very materially increased. —*Elektrische Betrieb*, March 24, 1923.

*Alternating-Current Locomotives in Northern Sweden.*—W. REICHEL.—The important cross-country railway in northern Sweden connecting Lulea and Narvik, both north of the Arctic Circle, has now been completely electrified and is, with a length of 475 km., one of the longest European electric railroads. The road is used primarily for the transportation of heavy iron-ore trains. Thirty to forty cars, each loaded with 35 tons of ore, is the average train capacity to be hauled, and a yearly total of five million tons has to be transported. The paper does not go into any detail concerning the locomotive type, but describes in a general way the experiences of operation on this unusual line with the older (1914) and the latest type of 1C+C1 engines. The machines cover on the average 12,000 km. per month, or, with 250 operating days, 150,000 km. per year. *Siemens Zeitschrift*, March, 1923.

## Telegraphy, Telephony, Radio and Signals

*Specializing Transportation Equipment for Telephone Construction and Maintenance Work.*—J. N. KIRK.—The author describes in a general way the application of motor vehicles and their associated apparatus in connection with outside plant construction and maintenance work, outlining through the successive stages of development what has been accomplished in this respect up to the present time. To give a comprehensive picture, the more primitive types of equipment, together with the manual methods of doing work, are shown in comparison with representative instances of higher development during the past few years.—*Electrical Communications (published by the International Western Electric Company)*, February, 1923.

*Practical Application of Carrier Telephone and Telegraph in the Bell System.*—A. F. ROSE.—The author summarizes the application of carrier current up to the present time and gives a few typical examples where it has been found economical to provide circuits by means of carrier current rather than by other types. At present in the carrier telephone system there are twenty-nine channels, representing a distance of 14,636 miles. In the carrier telegraph system there are 151 channels, representing 83,713 miles. Line diagrams of the more important systems are given.—*Bell System Technical Journal*, April, 1923.

## Miscellaneous

*Electric Piloting of Ships.*—The entrances of several large harbors are already equipped for electric piloting, which is made possible by a submarine cable laid along the bottom of the entrance channel. The cable is charged from its shore end with alternating current of 500 cycles, while its other end is grounded at sea. On each side of the piloted ship a coil is placed, and the current induced in these two coils is compared by listening on two telephone receivers. As long as the ship keeps directly above the pilot cable the sound in the two telephones will be of equal strength. The Siemens piloting system, however, does away with the necessity of steering by sound. The cable is energized with commercial alternating current of 50 cycles, and the induced current in the coils, after being amplified through a set of electron tubes, is used to actuate a double moving-coil instrument, with one coil and pointer for starboard and the other coil and pointer for port. To enable a ship equipped with the Siemens system to respond also to a 500-cycle cable, two sets of amplifiers are provided for the indicating instruments, one set for the low-frequency and one for the high-frequency current. The induction coils on board ship measure each 1,000 mm. by 650 mm. and may be swung flat against the side of the boat when not in use.—*Siemens Zeitschrift*, March, 1922.

# News of the Industry

**Chronicle of Important Events and General Activities, Announcements and Reports of Association Meetings, Court Decisions and Commission Rulings and News of Electrical Men**

## Drop Protest on Lock 17

**Alabama Power Company Likely to Get Permission to Build Plant—Power Loop Still Opposed**

WITH the withdrawal of a protest by the Birmingham Water, Light & Power Company against the granting by the Alabama Public Service Commission of a petition from the Alabama Power Company for permission to develop hydro-electric power at the government dam at Lock 17 near Tuscaloosa, it is thought certain that the company's petition will be granted. It was brought out at a hearing last Saturday that the projected plant would cost approximately $500,000 and would insure an annual saving of approximately $120,000 as compared with a steam plant. A 10,000-hp. unit can be ready for operation within twelve months from the time permission is granted. Successful operation of a plant at the site is dependent upon ability to tie in with transmission lines conveying the power to places where it can be used.

### Opposition to Power Loop

Strong objection was raised to the petition of the Alabama Power Company to build a transmission line from Sheffield to Huntsville, which, as shown in the Electrical World for May 5, page 1052, would complete a "power loop" in Alabama. The chief objection was that such a line would further hurt the chances of Henry Ford at Muscle Shoals.

It was revealed, however, that the Tennessee Valley is not a unit in opposing the plans of the Alabama company. Representatives of various cotton mills and other manufacturing enterprises at Huntsville, Sheffield, Athens and Albany-Decatur appeared before the commission and declared that their plants needed the power that would be carried over the new line. They called on the commission to grant the petition of the company at once.

## Public Service Company Is Mapping by Airplane

Following the growing practice of central-station companies of using airplanes in surveying the route for new transmission lines, the Public Service Electric Company of New Jersey is obtaining maps in this way instead of employing state and National Geographic Survey maps, as was its former practice. The state and national maps were made to a scale of 2,000 ft. to 5,000 ft. per inch, while the serial maps obtained from the airplane are on a scale of only 800 ft. to the inch and show in detail the surrounding territory. Relative heights of buildings, chimneys and trees are determined by the shadows on the ground. The character of the surface of the ground and of farm lands stands out in bold relief. Measurements made in the field between prominent land marks check accurately with the scaled-map distance.

In order to get accurate picture maps, the airplane flies at a uniform altitude of 10,000 ft. and many pictures are taken. When printed they are matched accurately, the sections which overlap being eliminated. The company has a continuous aërial map showing the meadows from Newark Bay and the Passaic River to Passaic and Paterson, also one of Hudson County, including the Kill von Kull, Bergen Point, Bayonne and part of Jersey City. A map is now being made of the southern division.

## Harris J. Ryan New President of A. I. E. E.

**Formal Ratification of Directors' Nominations Made at Annual Business Meeting—Net Growth of 1,035 in Membership, with 847 Section and Branch Meetings**

Prof. Harris J. Ryan
President-Elect A. I. E. E.

PROF. HARRIS J. RYAN of Stanford University, California, was elected president of the American Institute of Electrical Engineers at its annual business meeting, held in New York on May 18, and the other officers selected in March as "directors' nominees" were formally confirmed. The five new vice-presidents, who take office along with the president on Aug. 1, will be: From district No. 2 (Middle Eastern), William F. James, Westinghouse Electric & Manufacturing Company, Philadelphia; district No. 4 (Southern), Henry E. Bussey, General Electric Company, Atlanta; district No. 6 (North Central), Herbert S. Sands, Westinghouse company, Denver; district No. 8 (Pacific), J. E. Macdonald, Los Angeles; district No. 10 (Canada), S. E. M. Henderson, Canadian General Electric Company, Toronto. The three new managers are: William M. McConahey, Westinghouse company, East Pittsburgh; William K. Vanderpoel, Public Service Corporation, Newark, N. J., and H. P. Charlesworth, American Telephone & Telegraph Company, New York. George A. Hamilton, Elizabeth, N. J., was re-elected treasurer.

In the annual report of the board of directors, which was presented at this meeting, very satisfactory results of the membership committee's efforts were shown. The institute has now six honorary members, 578 fellows, 2,264 members and 12,450 associate members, a grand total of 15,298, which is a net gain of 1,035 as compared with the previous year. The report on activities of local sections and student branches showed that there are now forty-six sections and sixty-eight branches, a gain in each case of one over last year. Three hundred and forty-four section meetings, with a total attendance of 46,672, and 503 branch meetings, with a total attendance of 26,893, were held, making an aggregate attendance of 73,565 at 847 meetings.

Sixty-three deaths, five of fellows, ten of members and forty-eight of associates, occurred in the year.

## Another Step in Massachusetts Superpower Development

By the incorporation of the Montaup Electric Company of Fall River, Mass., with a capital stock of $7,500,000 divided into 15,000 shares of preferred and 60,000 shares of common stock, another forward step has been taken in the development of the superpower idea in the Bay State. As recently announced in the Electrical World, this company is formed to generate,

transmit and sell electricity from a new tidewater station to be built on Mount Hope Bay at Fall River, the systems of the Fall River Electric Light Company, the Blackstone Valley Gas & Electric Company and the Edison Electric Illuminating Company of Brockton to be the beneficiaries of the plan. Transmission lines and other equipment for the interconnection of these companies form a part of the program. The incorporators are S. B. Chase, president, and Henry B. Sawyer, treasurer, who, with R. F. Whitney, A. Stuart Pratt and V. D. Vickery, are directors.

## Eber Bill Amended

**Effort to Prevent All Water-Power Development in Wisconsin for Six Years Fails**

THE menace to the development of hydro-electric plants on water-power sites in Wisconsin by private companies which for a time was seriously threatened by the possible enactment of the Eber water-power survey bill was thought to have passed when the joint finance committee of the State Legislature voted on Thursday, May 17, to postpone a vote on the bill indefinitely. The proposed measure would have held up for six years all water-power development in Wisconsin pending an extensive survey by the Railroad Commission in the interest of state exploitation. A few days later, however, the Assembly ordered the bill engrossed, changing the six-year period of cessation to two years.

Among those who appeared in opposition to the bill at a hearing before the committee was G. C. Neff, vice-president of the Wisconsin River Power Company, who charged the sponsors of the Eber bill with trying to make the people believe that by developing water-power sites the entire state can be electrified. "This is untrue," he said. "Hydro-electric plants will serve only as supplementary sources of power. The steam plants will continue to be the dependable generating stations. If all the available water-power resources capable of economic development in Wisconsin were utilized and made available by 1930, it would amount to about only 25 per cent of the total electrical energy consumed." Mr. Neff also accused the sponsors of the bill of holding out the false hope that electricity can be generated so cheaply that it will take the place of coal in heating homes.

Russ A. Walter of Detroit, a personal representative of Henry Ford, also appeared in opposition to the bill. "Mr. Ford has already developed water-power sites in Michigan and has erected branch plants on his properties," said Mr. Walter. "The same policy will be followed in Wisconsin."

Mr. Walters upon being asked directly whether Mr. Ford planned to enter the water-power development field in Wisconsin in the next six years, replied that that was his plan.

## Water-Power Conference

**Eight Southern States, Including West Virginia, To Be Represented at Asheville Meeting**

AT THE second meeting of the Southern Appalachian Water Power Conference, to be held at Asheville, N. C., June 25-27, there will be in attendance representatives of the eight states of North and South Carolina, Virginia, West Virginia, Georgia, Tennessee, Alabama and Mississippi, including outstanding figures in public utility companies, public service commissions and state geological and conservation work, engineers, bankers and manufacturers.

One of the most important problems to come up will be interchange of power between companies in the several states, this involving not only economical and engineering but legal and industrial considerations. The possibilities of interconnection were vividly illustrated last summer and in the drought of 1921, when the Alabama Power Company diverted the power of the Gorgas steam plant near Muscle Shoals, sending it to the Georgia Railway & Power Company, which in turn transmitted an equal amount of energy to the Southern Power Company, the latter relaying the power received to the Carolina Light & Power Company for the use of its customers in Raleigh and neighboring sections. This operation involved a transfer of power over interconnected lines of approximately a thousand miles, operating in four states.

Another important question to be discussed will be the establishment of central steam plants to supplement hydro-electric stations. Preferably these plants would be built near coal mines and on streams affording a suitable supply of water for condensation. The only known site in North Carolina which fulfills the requirements is in the first stage of development by the Carolina Light & Power Company, which is building near Moncure a 15,000-kw. unit as a part of plans which contemplate an ultimate development of 60,000 kw. The plant is on the Cape Fear River and near the Deep River coal fields.

The conference will also consider an expansion of activities to include departments concerned with public relations, power companies, regulatory bodies and the general public, as well as departments for compiling and disseminating information as to natural resources, including water powers, minerals, forests, etc.

## Time for Obtaining New York Licenses Extended

Some confusion exists regarding the proper interpretation of the law passed in New York to govern the licensing of engineers, and as a result an emergency bill pushed through the Legislature and signed by the Governor has extended the period in which licenses may be obtained from May 5 to Aug. 1, 1923. The misunderstanding which originally existed has been further complicated by an interpretation of the law handed down at the last minute by Prof. A. S. Downing, in charge of its enforcement, to the effect that any person above the grade of plumber who may be compelled to exercise initiative, skill or judgment in engineering construction work must have a license. Interpreted more specifically in terms of electrical construction, this would mean that any construction man who builds a line and does not follow in detail a blueprint reviewed by a licensed engineer would be compelled to have a license.

The Empire State Gas and Electric Association points out that this interpretation makes no distinction between grades of engineering and allows anyone having a license to practice in any branch of engineering regardless of whether he is fitted to do so or not. Feeling that such a ruling is not justified, the Electric Section of the association, assembled at Utica May 17, voted in favor of appointing a committee to discuss with Professor Downing the proper interpretation of the law.

## Los Angeles City Authorities for Boulder Canyon Plan

A DEMAND on the municipal electric system of Los Angeles which is increasing at the rate of 20 per cent compounded annually is made the text of a folder prepared by the city's Department of Public Service for the information of its citizens. This folder says:

"The total quantity of power that can be developed by the city along the aqueduct and on Owens River streams amounts to about 220,000 hp. Contrast this available supply of electrical energy with the city's increasing needs. For the past five years the use of electrical energy in Los Angeles has increased at the rate of 22 per cent compounded annually. Assuming only a 15 per cent annual increase for the next seven years, by 1930 the entire city for all purposes will require 540,000 hp."

Boulder Canyon, on the Colorado River, is the logical source for the development of a large new hydro-electric supply for Los Angeles, in the opinion of the department. "Los Angeles should stand ready to secure its fair share of Boulder Canyon power," the folder says. "Boulder Canyon power, delivered to this city by its municipal electric system, will insure the continuation of low electric rates; it will supply the energy so urgently needed if Los Angeles is to continue to grow industrially and commercially. Los Angeles seeks only its fair share of this power after the requirements of all other communities within economic reach have been satisfied. In addition to supplying the urgent power requirements of Los Angeles and the Southwest generally, electrical energy developed at Boulder Canyon will provide the money to repay the federal government the entire cost of the high dam."

## Final N. E. L. A. Program

**Addresses by President Lowell of Harvard, Melville E. Stone and H. B. Swope Are Added**

OFFICIAL announcement by M. H. Aylesworth, executive manager of the National Electric Light Association, is to the effect that the program for the forty-sixth convention of that body in New York City beginning a week from Monday is now complete and the "best ever offered to any industry." Concerning some special features of the program Mr. Aylesworth says:

"The Public Relations Section will have a program for executives beginning Monday afternoon, June 4, at 2:30, dealing with all angles of this most important subject. On Monday afternoon Thomas A. Edison will deliver a message to the Public Relations Section which should mean a great deal to the industry. On Tuesday afternoon leading newspaper men will deliver timely addresses telling us more about publicity, and the subject will be thoroughly discussed in a symposium by chairmen and directors of state committees on public utility information. Herbert Bayard Swope, executive editor of the New York *World*, and Bruce Barton, editor and writer, will open the discussion. On Wednesday afternoon public utility commissioners from various states and electric light and power company executives will discuss public relations. Thursday afternoon has been set aside for the customer-ownership committee, and B. C. Forbes, publisher and financial writer for the Hearst organization and other syndicates, will open the discussion, while prominent leaders of the industry, including Samuel Insull and E. K. Hall, vice-president American Telephone & Telegraph Company, will address the meeting.

"The morning sessions, beginning Tuesday morning and closing Friday noon, will be addressed by prominent men in the industry and reports of great importance will be presented. Among those from without the industry who will talk at the four morning sessions are O. E. Bradfute, president of the American Farm Bureau Federation; Melville E. Stone, counselor Associated Press; Lewis E. Pierson, chairman of the board, Irving Bank-Columbia Trust Company; Dwight N. Lewis, president National Association of Railway and Utilities Commissioners; President A. L. Lowell of Harvard University, and O. C. Merrill, executive secretary Federal Power Commission. On the night of June 7, at Carnegie Hall, Julius H. Barnes, president of the Chamber of Commerce of the United States, will deliver an address on public ownership which will be carried by radio to the entire nation."

The addresses by President Lowell, M. E. Stone and H. B. Swope, as well as those by Samuel Insull and E. K. Hall, are features not included in the tentative program printed last week.

## Sixty-one Big Installations Under Way

**Larger Power Stations and Extensions Built in 1923 Will Have Rating of 3,546,000 Kva.—Nearly One-third of New Plants Are Hydro-Electric—To Cost $469,100,000**

BELOW is a tabulation of the chief power stations and extensions to existing power stations that are now under way and therefore belong in the electric building program of 1923. Nearly all of these have been noted in the ELECTRICAL WORLD at the time of their official announcement. As the table shows, twenty-one of them, with an aggregate rating of 1,145,000 kva., are hydro-electric, and forty, with an aggregate rating of 2,401,500 kva., are steam. There are eight entries of 100,000 kva. or more, the largest being the 210,000-kva. hydro-electric installation of the Niagara Falls Power Company and the next largest the 200,000-kva. steam plant of the Public Service Electric Corporation of New Jersey.

Geographically, the distribution (in kva.) is as follows: Middle West, 1,355,-500; Middle Atlantic States, 1,075,000; Southern States, 474,000; Mountain and Pacific States, 401,000; New England, 206,000.

### Electric Power Stations and Extensions Now Under Way

**(From the News Columns of the "Electrical World")**

HYDRO-ELECTRIC

| Company | Plant | Rating, Kva. | Company | Plant | Rating Kva. |
|---|---|---|---|---|---|
| San Francisco Municipal | Hetch Hetchy | 80,000 | Empire District Electric Co. | Table Rock | 60,000 |
| Metropolitan Power Co. | Susquehanna | 30,000 | Niagara Falls Power Co. | Niagara | 210,000 |
| Central Maine Power Co. | Skowhegan | 5,000 | Caddo River Power Co. | Ouachita | 90,000 |
| Western States Gas & Electric Co. | El Dorado | 30,000 | Pennsylvania Water & Power Co. | Holtwood | 30,000 |
| Portland Railway, Light & Power Co. | Oak Grove | 30,000 | Pacific Gas & Electric Co. | Pit No. 2 | 70,000 |
| Pacific Power & Light Co. | Deschutes | 7,500 | Great Western Power Co. | Caribou | 22,000 |
| New England Power Co. | Davis Bridge | 30,000 | Skagit River Power Co. | Skagit | 34,500 |
| Northern States Power Co. | St. Croix | 90,000 | Wisconsin-Minnesota Power Co. | Jim Falls. | 12,000 |
| Alabama Power Co. | Mitchell Dam | 90,000 | Los Angeles Municipal | San Francisquito | 25,000 |
| Denver Gas & Electric Light Co. | Boulder | 90,000 | Miscellaneous | | 35,000 |
| Georgia Railway & Power Co | Mathis | 62,000 | | | |
| Pacific Power & Light Co. | Hood River | 12,000 | Total | | 1,145,000 |

STEAM

| Company | Plant | Kva. | Company | Plant | Kva. |
|---|---|---|---|---|---|
| Louisville Gas & Electric Co. | Waterside | 20,000 | Indiana Electric Corp. | Wabash | 100,000 |
| East Penn Electric Co. | Pine Grove | 50,000 | Union Electric Light & Power Co. | Cahokia | 60,000 |
| Houston Lighting & Power Co. | Deepwater | 40,000 | Boston Edison Co. | Weymouth | 66,000 |
| Northern States Power Co. | High Bridge | 75,000 | Brooklyn Edison Co. | Hudson Ave. | 125,000 |
| Tri-City Railway & Light Co. | Moline | 26,000 | Duquesne Light Co. | Colfax | 60,000 |
| Commonwealth Edison Co. | Crawford Ave. | 70,000 | West Tennessee Co. | Springdale | 70,000 |
| Commonwealth Edison Co. | Calumet | 60,000 | Detroit Municipal | City | 100,000 |
| Sand Springs Power, Light & Water Co. | Sand Springs | 12,000 | Cleveland Electric Illuminating Co. | Lake Shore | 60,000 |
| Public Service Co. of Northern Illinois | Joliet | 30,000 | Southern Power Co. | Mount Holly, etc | 50,000 |
| Public Service Co. of Northern Illinois | Waukegan | 40,000 | Middle West Utilities Co. | Grand Tower | 50,000 |
| Connecticut Light & Power Co. | Devon | 75,000 | Ohio Power Co. | Philo | 70,000 |
| Tennessee Electric Power Co. | Nashville | 12,500 | Potomac Electric Co. | Washington | 25,000 |
| United Electric Light & Power Co. | Hell Gate | 70,000 | Counties Gas & Electric Co. | Barbadoes Island | 25,000 |
| Oklahoma General Power Co. | Muskogee | 27,500 | Philadelphia Electric Co. | Delaware | 60,000 |
| Oklahoma Gas & Electric Co. | Harrah | 20,000 | Toledo Edison Co. | Toledo | 37,500 |
| Pennsylvania Central Light & Power Co. | Saxton | 80,000 | Luzerne County Gas & Electric Co. | Kingston | 25,000 |
| New England Power Co., etc. | Montaup | 30,000 | Lorain County Gas & Electric Co | Elyria | 25,000 |
| Illinois Electric Power Co. | Peoria | 120,000 | Public Service Electric Co. | New Jersey | 25,000 |
| Detroit Edison Co. | Trenton Channel | 150,000 | Consumers' Power Co. | Zilwaukee | 100,000 |
| Public Service Electric Corp., (N. J.) | Kearney | 200,000 | | | |
| Public Service Electric Corp., (N. J ) | Essex | 60,000 | Total | | 2,401,500 |

TOTAL COST

| | | |
|---|---|---|
| Hydro-electric (21 Installations) | 1,145,000 kva., estimated at $200 | $229,000,000 |
| Steam (40 installations) | 2,401,500 kva., estimated at $100 | 240,100,000 |
| | 3,546,500 | $469,100,000 |

## Syracuse's Lighting Plan

**Well-Thought-Out System for Three-Million-Dollar Installation—Costs of Street Opening**

A PLAN adopted by the city of Syracuse, N. Y., for lighting its streets and described by K. V. Farmer at the Utica meeting of the Electric Section of the Empire State Gas & Electric Association last week provides for a thoroughly modern and well-considered system to cost $3,000,000. Briefly, the plan calls for four types of lighting, for business, main and secondary thoroughfares and residential streets. It includes the abandonment of 700 five-lamp ornamental poles and 2,000 4-amp. luminous-arc lamps on overhead lines. All the new lighting will be supplied from underground cables.

For business thoroughfares the plan provides cast-iron posts with two 6.6-amp. inverted luminous-arc lamps, spaced approximately 100 ft. apart, with the light source 18½ ft. above the street. On side streets one light is alternated on posts with the lamp source 14½ ft. above the street. For main thoroughfares cast-iron posts will also be used, with 400-cp., 7½-amp. incandescent lamps and large lanterns, the posts to be spaced 125 ft. to 200 ft. apart. For secondary thoroughfares the same type of post, with 400-cp. lamps spaced 200 ft. to 250 ft. apart and the light source 12½ ft. from the ground, is adopted, and for residential streets similar posts, spaced 150 ft. to 250 ft. apart, with small lanterns having a light source 12½ ft. above streets, are to be erected.

Mr. Farmer told of successful results achieved by gas companies through the use of compressed air in opening streets and making excavations. The Syracuse Lighting Company, he said, was considering also the use of a special plow built by the Philadelphia Electric Company for the installation of parkway cable in residential streets.

Following the presentation of Mr. Farmer's report, W. C. Blackwood, electrical engineer of the New York & Queens Electric Light & Power Company, declared that he is using 30 per cent Para rubber-covered single-conductor cable without a lead sheath in fiber conduit for series street-lighting circuits run underground. To increase the use of existing distribution lines and relieve the stations of equipment, type RO transformers will be connected to such lines for feeding street-lighting circuits.

Considerable time is being saved by the Brooklyn Edison Company in tearing up pavement preparatory to the installation of underground cable, R. A. Paine, Jr., outside plant engineer of that company, asserted, by using Ingersoll-Rand gas-engine-driven air compressors and hammers. Five of these are mounted on trailers for distant jobs, and five are on trucks for close-in routing. Space is being saved in substations by supplanting street-lighting tub transformers by pole-type regulating transformers of 10 kw. and 20 kw. controlled by time switches. These are connected to commercial 2,400-volt circuits and have been in successful use for seven years. About 150 time clocks are installed on the system, which require two men to keep them wound.

By installing moving-coil, pole-type, constant-current transformers for street lighting the Utica Gas & Electric Company expects to eliminate station fires and excessive maintenance of switchboards, E. P. Peck, general superintendent of the electrical department, declared. At the same time it will be able to control and meter the street-light circuit from a central point.

# Empire State Engineers Meet at Utica

**Street Lighting, Plant Economies, Hydraulic Design, State Survey of Interconnection Possibilities, Overhead Distribution, Underground Construction and Other Topics Discussed**

TIMELY engineering and operating problems were informally discussed by the Electric Section of the Empire State Gas and Electric Association at its meeting in Utica, N. Y., May 17 and 18, seven committees submitting reports. The manner of conducting the meeting was very effective and resulted in unusually valuable discussions. That on street lighting will be found at left.

Announcement of a survey of power and communication parallels in New York State now being made by the Empire State Gas and Electric Association in co-operation with the National Electric Light Association was made by W. F. Davidson of the Brooklyn Edison Company. Extensive studies are being made of the length of these parallels, the separation of the lines, voltage, frequency, type of power system and telephone circuit, satisfactoriness of telephone service, etc. This information is being collected to show the fallacy of placing drastic limitations on the proximity of power lines to telephone lines, it having been advocated in some sections that 2,300-volt parallels be limited to 3,000 ft. with 60-ft. separation and 110,000-volt parallels separated at least 1,500 ft.

It was pointed out by W. M. Carpenter, assistant secretary of the association, that rural service will be delayed if too drastic restrictions are placed on power and communication parallels.

E. P. Peck advised operating companies to consult the National Electric Light Association regarding their inductive interference problems rather than to try to handle them themselves.

Two peculiar cases of inductive interference were related by O. C. Davidson, Rochester Gas & Electric Company, and C. P. Scheller, St. Lawrence Transmission Company, which indicated the necessity of considering the circuit as a whole and not merely the parallels.

### Economies in the Boiler Room

Experiences in improving the operating economy of a specific plant were related by A. C. Jordan, general superintendent of the Elmira Water, Light & Railway Company. Particular attention was directed to reducing banking losses, blow-down, auxiliary steam and economizer troubles. By changing the method of banking the amount of coal required was reduced two-thirds; it now amounts to about one-tenth of a pound per boiler-horsepower per hour. Foremerly a station which had about 5,000 hp. in 750-hp. boilers had to blow down 15,000 lb. of water per day. Now they are not blown down at all. The boilers are filled once every three weeks with fresh water and 100 lb. of soda ash and tested regularly with a conductivity meter for salt content. When the concentration exceeds 35 grains per gallon the boiler must be blown down, but this has not been found to be necessary during the period of three weeks in which the boilers are operated continuously at 200 per cent. At the end of this time the boilers have to be shut down for maintenance anyway.

A study of the auxiliary steam requirements of circulating and boiler-feed pumps disclosed the fact that they were taking 50 per cent of the auxiliary steam. The equivalent steam consumption was greatly reduced by electrifying the auxiliaries and bleeding steam from the turbines for feed-water heating. In addition, the pump speeds were reduced to minimize the friction head and spring water at 56 deg. F. taken from driven wells mixed with river water at 32 to 80 deg. F. for circulating water. Means for adjusting the speed of pumps were highly favored.

Experiments with the best temperature of feed water for economizers disclosed the fact that it should be somewhere between 120 deg. and 157 deg. to avoid the extremes of sweating or steaming.

### Tendencies in Hydraulic Design

The design and installation of hydraulic equipment are tending toward simplicity, according to C. P. Scheller, St. Lawrence Transmission Company, who spoke on developments in this equipment. Impeller-type waterwheels are coming into use for heads up to 30 ft. While the efficiency of the unit is not so high as that of some other types of wheels, still its speed is so much higher that the over-all efficiency of a plant involving these units will be about the same. Straight-draft tubes are showing higher efficiency, and utilization of the siphon principle is enabling the setting of waterwheels above the pond level where this is not too much above tailwater. Integral-type governors attached to the turbine shaft are coming into use, and in some cases separately mounted flyball governors driven by synchronous motors are being used to

eliminate connections with the turbine. Oil-lubricated, babbitted bearings are gradually replacing lignum-vitæ bearings. Separate pumps for each bearing are also coming into use.

Committee work in New York State concerning the feasibility of greater interconnection within the state, as well as with systems in adjoining states, was outlined by E. P. Peck, general superintendent electrical department, Utica Gas & Electric Company. (See page 741, ELECTRICAL WORLD, Mar. 31.)

### OVERHEAD DISTRIBUTION PRACTICES

The report of the committee on overhead distribution, of which H. W. Watt, electrical engineer Westchester Lighting Company, was chairman, was presented in the form of separate papers by the members of the committee. Attention was called to the need of more accurate determination of the rupturing capacity of fuses, especially for underground service, by W. F. Butcher, who presented tables listing the ratings of various makes of fuses as well as the size of fuses used on transformers by five companies. H. S. Chartier pointed out that maps of overhead systems must be readily intelligible to every one who has occasion to use them; they must be easily made and not difficult to maintain, and they must be in easily accessible places and protected from dust and exposure. One method of meeting these needs was outlined.

Essential requirements in the design of three-phase, four-wire distribution systems were discussed by J. O. Montignani, Westchester Lighting Company, who contended that general interconnection of alternating-current mains has not proved practicable. Furthermore, he held, distribution circuits should not be allowed to ramble off from the territory assigned to them. Attention was called to the fact that the inductive reactance of No. 2/0 wire is about one and one-half times the ohmic resistance at 18 in. separation. In arranging the wires on cross-arms a definite and systematic plan should be followed and insulators of somewhat higher rating than the voltage of the line should be used. Economical alternating-current distribution, declared Mr. Montignani, requires the use of secondary mains of as great a length as possible fed by larger transformers. To permit isolating trouble the branch circuits should be provided with suitable cut-outs. The value of installing lightning arresters on distribution transformers was also emphasized.

Pole lines have not been sufficiently guyed in many places, C. W. Nickerson contended. He maintained that when a transmission line is constructed through open country and subjected to high wind pressure it should be guyed in both directions about every tenth pole. Tree guying was discouraged.

According to tests of poles reinforced with a concrete collar around the butt, newly reinforced poles give a strength at the ground line equal to, if not greater than, that of the original pole, L. B. Snyder asserted. Subsequently defects develop, however, such as shrinking of the pole within the concrete collar and resulting troubles from the accumulation of moisture. At best, this method only postpones replacement of the pole a few years, Mr. Snyder contended, and when replacement becomes necessary the added cost of removing and disposing of the concrete bases more than offsets the gain derived from the added life of the pole.

J. M. Howarth dealt with the economic loading of line transformers, and certain features of construction and operation which have a definite bearing upon the design of secondary systems were outlined by C. A. Bacon, Adirondack Power & Light Company. Mr. Bacon discussed methods of ascertaining the load to be handled, the effect of demand and diversity factors on wire and transformer sizes and approximate methods of calculating residential consumers' demand.

Operating a transformer underloaded is an inefficient utilization of the investment represented and is, furthermore, productive of low power factor and excessive core loss, declared Chairman Watt. Hence it should be avoided as much as exceeding the upper temperature limitation. Five methods of determining the loading of transformers were discussed, namely, record of meter load, voltage tests during peak load, indicating ammeter and wattmeter readings on secondary, recording ammeter or wattmeter, and use of a thermal indicator. The combination of thermal indicator with recording ammeter and recording wattmeter was recommended.

### SECTIONALIZING SWITCHES USED

In discussing the reports on overhead distribution W. G. Blackwood said that branch circuit cut-outs are not used by the New York & Queens Company because troubles on a circuit will interrupt service. Instead sectionalizing switches are used. Banking of transformers has been successfully employed on overhead and underground circuits for several years, expulsion fuses being used in the secondaries of small transformers and oil switches with large ones.

E. P. Peck spoke of the use of a common neutral for every purpose in Minneapolis. The system of the city is grounded at every possible point, considerable money being thereby saved. There is not much trouble in banking transformers, he said, if fuses rated at four times normal current are used in the primary or secondary side of the transformers.

The smallest transformer fuse used by the Brooklyn Edison Company, according to R. A. Paine, Jr., is 50 amp. With 50-kw. and 75-kw. transformers 75-amp. fuses are used and for 100-kw. transformers 100-amp. fuses are used. In specifying sizes of transformers that can be mounted on poles, he said, it is preferable to speak in terms of weight, rather than rating.

With three-phase, four-wire systems more tree trimming and more tree wires are required to insure uninterrupted service, H. W. Watt observed. W. C. Blackwood said that to insure economic loading of transformers the New York & Queens Company takes graphic readings at different periods. During the intervals the number of apartments, stores, etc., connected is recorded. Transformers of 25 kw. and larger have thermal indicators.

### UNDERGROUND SYSTEMS

Nine questions are to be specially investigated by the underground systems committee during the coming year, according to the announcement of R. A. Paine, Jr. They are conduit and manhole construction, manholes for transformers rated at 100 kw. and above, the best loading for cables, fireproofing cables, type of cables for four-wire three-phase systems, primary cut-outs for subway transformers, primary fuses or "disconnects" for underground lines, secondary distribution circuits (fused secondaries, single versus banked transformers, networks), and joints for high-tension cables. A. Hussey, Brooklyn Edison Company, presented a paper commenting on these and other subjects.

T. R. Eilenberg, New York & Queens Electric Light & Power Company, referred to some new manhole construction which has been adopted, new-type cable hangers and new distribution boxes which facilitate the location of trouble.

Creosoted-wood ducts are being used for primary and secondary services very successfully, Mr. Paine asserted. He referred to single-conductor, 45,000-volt cable with 20/32-in. paper insulation being installed by the United Electric Light & Power Company between the Sherman Creek station and the Hell Gate station, a distance of 11 miles. An installation of single-conductor, 66,000-volt cable with 30/32-in. paper insulation is being made by the Detroit Edison Company.

Experiences with high-voltage cable were related by W. F. Davidson, Brooklyn Edison Company, who called attention to the fact that ordinary compounds broke down in a relatively short time (thirty to fifty-five minutes) when 80,000 volts was applied between conductors and sheath owing to the formation of air bells in the compound. Petrolatum is now being used with much better results. The question is whether it will stay in the joints. It is possible that reservoirs may be required to keep the joints filled. Joints filled with this compound have been operated at 120,000 volts, three-phase, and 95,000 volts between conductors and sheath for seventy hours without failure, with "Conducell" partitions around the joints and no hand wrapping.

### RURAL SERVICE SITUATION

Rural service should be developed along such lines that it will be self-supporting, declared W. J. Reagan of the Utica Gas & Electric Company. He contended that the rural charge should be equal to the urban charge plus an excess charge equal to the additional expense of furnishing rural service.

## Clarion River Equipment

**Half of Apparatus for Piney Plant Now Ordered—Potential Development Reaches 400,000 Hp.**

THE first order for electrical equipment for the Clarion River project of the Penn Public Service Corporation has been placed by the General Construction Corporation with the Westinghouse Electric & Manufacturing Company and consists of two 12,000-kva. vertical waterwheel generators with transformers and switching equipment. This equipment will be installed in the Piney Creek power house, which will be the first of the three generating stations in the project to be put in operation. It is expected that this plant will be ready in 1923.

The plans for the Clarion project call for the construction of three dams and generating plants. One of these, known as the Foxburg development, is to be about two miles from the mouth of the Clarion River, which empties into the Allegheny 60 miles north of Pittsburgh. The second, the Piney development, is about 24 miles upstream. The third is still farther upstream, about 6 miles above the town of Clarion, Pa., and is known as the Mill Creek development. The dam at Piney will be about 75 ft. high, that at Foxburg about 175 ft. and that at Mill Creek about 250 ft.

The ultimate installation at Piney will be 44,000 hp., at Foxburg 88,000 hp., and at Mill Creek 130,000 hp. One half of the apparatus for the Piney plant is included in this first order.

The Clarion River is formed by the union of two branches 90 miles north of Foxburg and is fed by many other tributaries in its drop of 500 ft. to the Allegheny. Its total drainage area is 1,257 square miles, most of which is unsettled and unimproved forest land. When completed, the project will impound about 47,550,000,000 cu.ft. of water in the watershed of the Clarion River and its lower tributaries, a volume sufficient to develop 400,000 hp. of electrical energy. A total expenditure of about $28,000,000 will be necessary to complete the project. It is proposed to use the electric power for the industrial development of northwestern and western Pennsylvania and regions in eastern Ohio.

## Ford Reveals His Plans for High Dam Development

The formal application of the Ford Motor Company for a license covering the High Dam project at St. Paul was filed with the Federal Power Commission on May 22 by J. H. Manning, the managing engineer for Stone & Webster. This action is in pursuance of the terms of the preliminary permit which the Federal Power Commission granted the Ford Motor Company after the hearing held on March 2.

The application for license was accompanied by detailed plans of the development which appear to have met the commission's approval. Under the law these plans must be approved by the Secretary of War and the Chief of Engineers as well, because of the relationship between this project and navigation structures.

It will be necessary to cofferdam off the structure and make slight modifications in the original concrete to allow for the newer types of machinery which will be installed. In addition, the power house must be built and the necessary transmission equipment installed. The plans of the Ford company include a steam plant which is to be erected adjacent to the hydro-electric plant, or possibly may be housed in the same building.

## Municipal Ownership Mayor Elected in Denver

Ben F. Stapleton was elected Mayor of Denver on May 15 over D. C. Bailey in a bitterly contested fight in which municipal ownership of utilities played a chief part. Mr. Bailey, the present Mayor, had opposed the idea of the municipality acquiring its utilities. Mr. Stapleton, who had Governor Sweet's support, favored it, though not so unequivocally as five other candidates who went to defeat along with Bailey. Stapleton explained his platform as "the protection of the city's interests in the operation of public utilities and purchase of such utilities as can be purchased at a price which will permit the people to operate them advantageously." By the Denver charter all questions of franchises and ownership of public utilities must be submitted to the voters. Such a vote cannot be held for three years, but the newly elected Mayor's term will not have expired then.

## General Goethals Is Called in at Colorado Springs

The long-continued argument between the city of Colorado Springs and the Colorado Springs Light, Heat & Power Company over the amount of power that can be derived from the Pike's Peak watershed entered on a new phase recently when the city engaged G. G. Anderson, a Los Angeles engineer, to make a report. Mr. Anderson sustained the city's contention that there was sufficient water power obtainable to make it possible to supply the city from a strictly hydro-electric plant. This contention is disputed by the central-station company, which maintains that it will be necessary to have a steam station in reserve. In an endeavor to settle the question, the company has engaged Gen. George W. Goethals to survey the watershed and submit a finding.

On June 12 the voters are to pass upon the renewal of the company's franchise. If it is finally determined that no steam plant is necessary, the city plans to charge the company $100,000 annually for the use of the water. At present the company generates by both water and steam power.

## Johns Hopkins in Line

**Follows Trend of Engineering Education by Establishing New Arts Course for Technical Men**

THROUGH co-ordination between the Johns Hopkins School of Engineering and the College of Arts and Sciences it is planned to establish at the Baltimore university next October a preliminary arts course for students who expect to take later courses in mechanical, electrical, civil, chemical or gas engineering.

The new course will extend over a period of three or four years, depending upon the student's ability, after which he will be allowed to complete a regular engineering course in two additional years. The student will receive the degree of bachelor of arts at the end of his pre-engineering course and the regular bachelor of engineering degree upon completion of the two-year technical course.

The plan virtually tends to establish engineering training at Johns Hopkins upon a graduate basis, Dr. John B. Whitehead, dean of the engineering school, said, although it will not establish the pre-engineering course as a requirement for entrance to the engineering school and the regular four-year undergraduate courses in engineering will be continued as heretofore.

"The new course," Dr. Whitehead said, "has been arranged with special reference to the increasing demand for engineers who, in addition to the professional training, shall also have some knowledge of literature, history, modern languages, economics, business, other sciences and in general of those subjects usually understood as being part of a liberal education. It is now generally recognized that the larger undertakings of modern business and social enterprise require for their proper execution engineers who shall have as wide a knowledge as possible of social, political and economic affairs. A broad education is essential for this knowledge, and these courses are arranged with this purpose in view."

## Detroit May Purchase Generating Equipment

Although the Detroit City Council, which recently voted to award contracts to the Westinghouse Electric & Manufacturing Company for four 20,000-kw. turbo-generators, has rescinded this action, it is said to be likely that the city will eventually buy two, or possibly three, turbines to generate the 35,000 kw. or 40,000 kw. additional energy that it needs for lighting and pumping purposes and in the operation of the municipal railway. At present the city is generating about 19,000 kw. for these purposes and purchasing the rest from the Detroit Edison Company. It is the plan of the city administration to generate all the power needed for municipal uses, but not to compete with the central-station company in the supply of private customers.

## Against Excess Varieties

**Their Elimination Chief Topic of Discussion Among Jobbers at Hot Springs, Va.**

PROBLEMS involved in the elimination of obsolete, duplicate and other excess varieties from jobbing lines were the principal topics of discussion in the committee meetings and about the hotel at Hot Springs, Va., this week, when the Electrical Supply Jobbers' Association met for its fifteenth annual convention, meetings of the executive committee beginning on Monday and the convention proper on Wednesday. There was an unusually large attendance of both jobbers and manufacturers. No detailed recommendations are available as the ELECTRICAL WORLD closes its forms, but definite suggestions are expected which will clearly indicate the attitude of the jobbers on this subject.

E. W. Lloyd, chairman of the Joint Committee for Business Development, addressed the first session, and addresses by W. A. Durgin of the Department of Commerce, Congressman Clyde Kelly of Pennsylvania, C. G. Frang of the Apex Electrical Distributing Company, Cleveland, and J. Clyde Marquis, Department of Agriculture, were scheduled for Thursday.

A resolution was passed by the association in executive session to discontinue the separate meetings of the Central and Atlantic Divisions and to recommend that the Pacific Division hereafter hold but three meetings each year. O. Fred Rost was elected chairman of the Atlantic Division and W. R. Herstein chairman of the Central Division to serve for the ensuing year. The following were chosen to represent the divisions on the association's executive committee: Atlantic Division, E. C. Graham, V. C. Bruce Wetmore; Central Division, W. W. Low, George W. Johnson.

## Pacific Coast Jobbers Hear from Central-Station Men

Commercial managers of several of the large power companies of the Pacific Coast were present at the regular quarterly meeting of the Pacific Coast Jobbers' Association held at Del Monte, Cal., May 10 to 12. The credit men's association held their annual meeting at the same time, and one joint evening meeting was held at which several papers were presented. The credit men spoke of the upward trend of prices and the shortage of materials and warned against the fictitious activity that will result from the pyramiding of orders. At the open meeting Saturday morning central-station men told of the progress of the various co-operative movements on the Pacific Coast. A. E. Holloway, sales manager of the San Diego Consolidated Gas & Electric Company, told of a code of ethics which has been distributed among the contractor-dealers of San Diego and the success with which this movement is meeting. The next meeting of the jobbers' association will be held in the Northwest, probably in Portland, during the early part of September.

## Effort to Abolish Tennessee Commission Fails

Efforts to abolish the Public Utilities Commission of Tennessee have so far proved unsuccessful, the Legislature of the state having adjourned without passing an act of repeal. As reported in the ELECTRICAL WORLD at the time, Governor Peay on March 20 sent to the Legislature a special message advocating repeal. The House by a majority of seventy-four to thirteen had already voted for this course, but the Senate tabled the bill by a vote of eighteen to eleven.

At the hearing before the public utilities committee of the Senate the Mayors and the City Attorneys of Memphis and Chattanooga advocated repeal, while the officials of Nashville and Knoxville took an opposite view.

A bill increasing the personnel of the commission to five and adding a special lawyer to serve as counsel for cities and consumers passed the Senate, but was not brought up for consideration in the House.

## Conference Is Against Inclosing Attrition-Mill Motors

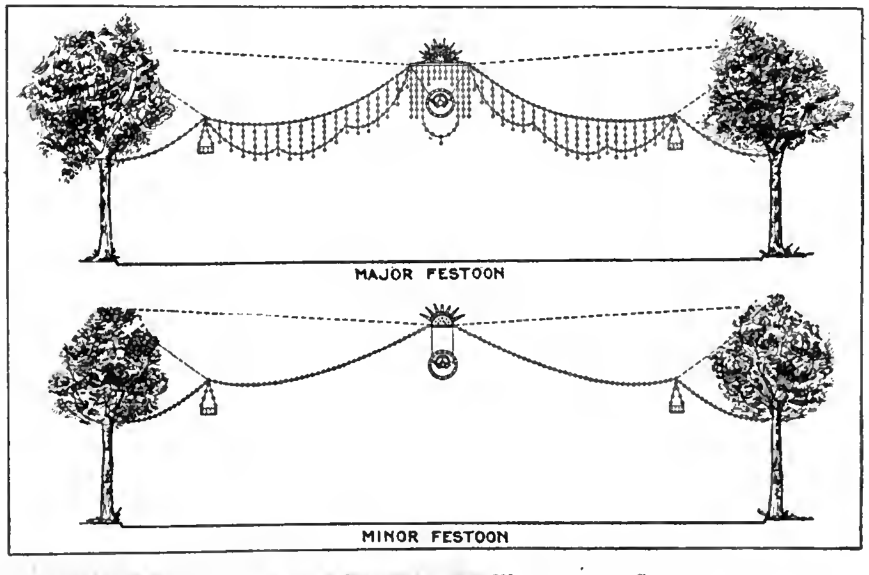
That squirrel-cage motors directly connected to ball-bearing attrition mills should not be inclosed was the finding of a recent conference composed of representatives of the Mutual Fire Prevention Bureau, the Electric Power Club and the attrition-mill manufacturers. It was held that rules must be based on facts and past experience rather than on the idea of trying to prevent something that may happen, and the point was made that the hazard with an inclosed ventilated motor or totally inclosed motor of ordinary construction might be greater than with the open-type squirrel-cage motor. No tests have been made to determine the relative factors of safety of the different types of construction. Experience, however, was held to have shown that the open-type squirrel-cage motor used on attrition mills for the last ten years has been satisfactory.

## Washington to Have Elaborate Electrical Display

Electrical decorations and special illumination for the streets of Washington for the convention of the Knights of the Mystic Shrine, to be held June 5, 6 and 7, will cost approximately $75,000, including installation. The principal display will be along Pennsylvania Avenue. From the peace monument at the Capitol to the Treasury Building, a distance of about one mile, the avenue will be illuminated by five major and fifty-eight minor displays. The major displays will consist of two ropes of lights across Pennsylvania Avenue, with lace effects between, a starburst and illuminated picture in the center and a design near each end. The lights will be red, green and yellow. Each major display will contain 700 lamps. The minor installations will consist of a single rope, with design in center, and each containing 350 lamps.

On Pennsylvania Avenue in front of the White House, where reviewing stands will be erected and the "Garden of Allah" created, there will be special floodlighting. In front of the Union Station a large electrical design, 30 ft. x 60 ft., is to be erected.

Poles have been set in Pennsylvania Avenue for the special installations and the underground power lines of the Potomac Electric Power Company will be tapped. The illumination will be used from May 26 to June 10. Plans prepared by the Westinghouse Lamp Company, slightly modified to meet financial needs, are being followed, and 25,000 Westinghouse "Mazda" lamps are to be installed.



OVERHEAD ELECTRICAL DISPLAYS FOR WASHINGTON CELEBRATION

## Texas Associations Unite

### Technical, Commercial and Accounting Discussions Fill Electrical and General Sessions at Fort Worth

DISCUSSING the methods used in changing 2,300-volt, single-phase and two-phase overhead lines to 4,000-volt, three-phase, four-wire, John Oram of the Dallas Power & Light Company pointed out, in a paper presented at the Fort Worth convention of the Southwestern Public Service Association last week, the advantage the latter system possesses in making use of 2,300-volt transformers previously installed. In changing polyphase circuits the changes are best begun in the outlying districts, he said, but with single-phase groups it makes little difference where the beginning is made. With a four-wire, two-phase system everything can be got ready while operation is continued at 2,300 volts, and the change can then be made in convenient steps, the noon hour having proved a good time to make cut-overs. Mr. Oram dwelt on the necessity of keeping proper clearances between conductors and structures and in climbing spaces on such cut-over lines and recommended that standard construction drawings be prepared for the guidance of the line crews. He pointed to the flexibility of the four-wire, three-phase circuits in providing any desired service through transformer connections recognized as standard and to the possibility of using special connections where these are necessary.

#### Operating Problems

Secondary and lightning-arrester grounds received attention in the round-table discussion of utility engineering and operating problems, and it was brought out that the Texas Power & Light Company has found 1-in. x 8-ft. ground rods more satisfactory in providing good grounds than the usual pipe where there are no water systems to use for grounding purposes. This is due to the greater tendency of pipe to corrode.

J. B. Thomas said that the ground rods used had pigtails attached at the factory, and the tendency on the part of line crews was to drive them full length into the ground, whereas if pipe is used the tendency is to saw the pipe off at some convenient point short of permanently moist earth.

It was stated in the discussion that the grounding of transformer cases has been abandoned in some instances because safety and accident prevention authorities felt that ungrounded cases were less of a hazard to linemen. That the practice would be resumed later was the opinion expressed by several who felt that grounded cases are less hazardous than ungrounded ones because the grounds are a protection in case of contacts between the primary circuits and the cases. The abandonment of grounded transformer cases has brought a reduction in the number of bushing failures, though this was attributed in part at least to the possibility that defective bushings would continue in operation for some time where the cases were ungrounded, while with grounded cases prompt breakdowns would occur.

The use of covering on line wires gave rise to a lively discussion, the opinion of the meeting being that as a means of showing the public and the legal authorities that bare wire is the safer practice on circuits of 2,300 volts and higher it should be actually used wherever possible.

#### Broad Functions of Arkansas Information Committee

Earl W. Hodges, director of the Arkansas Committee on Public Utility Information, proclaimed as the real foundation of utility prosperity good public relations. He said that in Arkansas it had been decided that development of the state resources was one of the important duties of his committee, and to that end efforts have been directed toward establishing relations with all kinds of societies in the state, including industrial, legal, ministerial, educational, civic and social.

In the Accounting Section meetings on Wednesday and Thursday customers' record and billing methods, preservation of records and budget estimates and analyses were discussed. Machine billing methods were the main subject under this heading. In the matter of preserving records it was felt that the general records should be preserved indefinitely. Supporting records should be preserved at least until an audit is made. It was shown that utility commission requirements influence the time of preservation of such records and that in the case of bills-payable records and other records of this character property appraisals at any time in the history of the property might make such records invaluable. Careless methods of filing in the past were shown to have made it difficult to use records even where they had not been destroyed.

Ice plants and power sales to them received attention in the Commercial Section on Thursday.

#### Amalgamation Effected

At the business session on Thursday afternoon the amalgamation of the Southwestern Public Utility Association and the South Central Gas Association was completed. This brought the light and power, electric railway and gas utilities of Texas all into the same association under the name of the Southwestern Public Service Association. The Fort Worth convention, at which nearly 450 delegates were registered, was a joint one. The chairman of the light and power section for the coming year is H. E. Borton of the Calvert Ice, Water & Electric Light Company, Calvert, Texas. The association officers are: President, J. H. Gill, Dallas Power & Light Company; first vice-president, C. B. McKinney, Lone Star Gas Company, Dallas; second vice-president, H. E. Borton, Calvert; third vice-president, George I. Plumber, Dallas.

## Pelton Wheel Built to Resist Dilute Sulphuric Acid

An engineering problem of more than ordinary interest has been worked out by the Pelton Water Wheel Company's Atlantic department in a contract just awarded for new hydraulic equipment by the city of Manizales, Republic of Colombia. This little city of the high Andes is more than a hundred miles from the railroad, and designs for a complete 500-hp. power-house installation have had to be worked out in sectional form to permit transportation by wagon, muleback and aërial tramway over mountain passes.

This, however, was not the only problem involved. The mountain torrent supplying power for the Manizales municipal light station, situated at the bottom of a deep canyon, is strongly impregnated with sulphuric acid. This has been traced to a subsurface flow through a stratum of volcanic rock extending far up the slopes above the city. So far as known, the Manizales plant is the only one in the world which runs on dilute sulphuric acid. Naturally no ordinary impulse wheel would last long in such service, as the acid would eat away every bit of steel with which it came in contact in a comparatively short time.

The Pelton design, consequently, had to be worked out on a basis permitting the use of bronze, brass and monel-metal, instead of steel, at every point that would be exposed to the water. This was successfully accomplished, as was the companion task of sectionalizing the entire equipment for transportation in small pieces and assembling on the spot, without prejudice to the strength or efficiency of the whole installation. The turbine except for these features is a standard type of Pelton impulse wheel. It will work on an effective head of 250 ft. and will be connected with a General Electric 350-kva. 60-cycle three-phase generator. The entire hydraulic installation and all auxiliaries will be built in the I. P. Morris Department shops of the William Cramp & Sons Ship & Engine Building Company, at Philadelphia.

## Utility Information Bureau Set Up in Pennsylvania

As foreshadowed in the notice of the preliminary meeting for that purpose of Pennsylvania public utility executives published in the ELECTRICAL WORLD of April 7, the Pennsylvania Public Service Information Bureau has been established for "the timely assembling and dissemination of reliable information relating to the commonwealth's public utilities." Electric light and power companies, electric railways, telephone companies, gas companies and water companies are behind the committee, of which P. H. Gadsden, vice-president United Gas Improvement Company, is chairman, and Walter H. Johnson, vice-president Philadelphia Electric Company, a prominent member. Headquarters are in Philadelphia.

## Brief News Notes

**New Municipal Ownership Provision in Wisconsin.**—The Teasdale bill has finally become a law in Wisconsin following its approval by Governor Blaine. It provides that no municipality that has acted to acquire privately owned electric light and power, street and interurban railway, gas or water systems may discontinue such action within thirty days after the commission has announced the necessary compensation for the properties to be taken over.

**San Francisco Installing 80,000 Kw. in Four Units.** — Generators for the Moccasin Creek power house of the city of San Francisco have been shipped from the factory of the General Electric Company at Schenectady, N. Y. Four units of 20,000-kw. rating each are to be installed. The new power house to contain this equipment will be of steel and reinforced concrete. It is planned to have the plant in operation within eighteen months.

**New River Project Must Be Readvertised.**—The Virginian Power Company has created a subsidiary to be known as the West Virginia Power Company. This subsidiary is intended to carry out the proposed development on New River. The change in name will make necessary the readvertisement of the preliminary permit for which the Virginian company applied. The advertisements, under the law, must be spread over a two-month period.

**Holtwood-York Transmission Line Nearly Finished.**—The transmission line which the Pennsylvania Water & Power Company is building from its generating station at Holtwood, on the Susquehanna River, to York, about 30 miles north, has been completed to within about a mile and a half of the substation which is to be built at Violet Hill, a short distance south of York. From this station energy will be supplied not only to York but also to Glen Rock, Red Lion, Railroad, Stewartstown and probably Spring Grove and Hanover.

**Standardization of Traffic Signal Colors.**—Forty-two men, representing the manufacturers and users of traffic signals, federal and state governmental departments, associations interested in the prevention of traffic accidents and representatives of the general public, are now drafting a national code on colors for traffic signals which it is expected will not only cut down the annual loss of life through traffic accidents but will eliminate many irritations to motorists and the operators of steam and electric railways. This work is being carried on under the auspices of the American Engineering Standards Committee. W. P. Blackwell of Newark, N. J., represents the National Electric Light Association and Clayton H. Sharp the Illuminating Engineering Society.

**Muscatine Company Changes Name.**—The Muscatine Hydro-Electric Power Company has amended its articles of incorporation to change its name to Eastern Iowa Power Company. Work began on May 1 on the dam which the company is erecting across the Maquoketa River at Muscatine, and it is expected that the plant will be ready for operation by Dec. 1.

**American Power & Light Company Pays Stock Dividend.** — The American Power & Light Company has, in addition to its regular quarterly cash dividend of 2½ per cent on its common stock, declared a dividend of 2 per cent payable in common stock. Both dividends are payable June 1 to stockholders of record May 19. This is the second holding company organized by Electric Bond & Share Company interests to pay stock dividends, the American Gas & Electric Company being the first.

**Giant Electric Sign for Standard Oil in St. Louis.**—A giant electric sign erected at a Standard Oil filling station just southwest of Forest Park in St.

Louis is said to be the largest double-faced sign in the world. It is 45 ft. high and 70 ft. long and is visible for a long distance either east or west. It is placed on sixteen concrete piers sunk 8 ft. in the ground. There are forty-two circuits and it requires five thousand lamps, varying in size from 10 watts to 100 watts, for its complete illumination. The words "Red Crown Gasoline" are outlined in red, the border lights are blue, and the remainder of the lights on the sign are white. The sign is illuminated from dusk to midnight each night. It was designed and built by the W. F. Williamson Advertising Service of St. Louis.

**Financial Success of St. Louis Electrical Exposition.**—The accounts of the St. Louis Electrical Board of Trade Electrical Exposition Company, under whose auspices the electrical exposition was held on March 12 to 17, show remarkable returns. The balance after all bills were paid enabled the company to pay to each exhibitor a sum equal to 24 per cent of the amount paid for rental of space and to return to each of the stockholders the amount he paid into the treasury at the time the company was organized.

**New Turbine for Okanogan Valley.**—The Washington Water Power Company, which recently acquired the property of the Okanogan Valley Power Company, has awarded a contract to the Pelton Water Wheel Company for furnishing a 2,500-hp. double-runner cylindrical-case reaction turbine, to operate under an 80-ft. head. This unit will be installed at the Similkameen River plant of the power company at Oroville, Wash. It will resemble in general design the Pelton turbine of the same capacity now operating at the plant, which was built for the Okanogan Valley Power Company in 1919.

**Utah Power & Light Shows Increased Earnings.**—Gross earnings of the Utah Power & Light Company for the twelve months ended Feb. 28 amounted to $7,338,990, an increase of $669,770 over last year. Net earnings after taxes totaled $3,670,866, compared with $3,205,190. Balance after preferred dividends was $1,184,547, an increase of $227,176.

**Charleston (W. Va.) Company Acquired by American Gas & Electric.**—The American Gas & Electric Company of New York has acquired the West Virginia Water & Electric Company of Charleston, W. Va., according to an announcement by A. C. Babson, general manager of the latter company. The West Virginia company supplies electric power and water to Charleston and surrounding territory. Details of the deal have not been made public. Electric light and power companies in Wheeling and in Logan, W. Va., are owned and operated by the New York corporation.

**Harvard Offers $1,000 Engineering Scholarship.**—A competitive scholarship of $1,000 has been offered by the Harvard Engineering School for the year 1923-24, to be open to seniors graduating in June from colleges or departments of liberal arts throughout the country. No student now in Harvard will be eligible for the competition, nor any student registered in any engineering or technical school. The award will be based on the complete academic record of the applicant, together with the result of a special three-hour written examination, including mathematics through calculus and general physics.

**Electrical Growth of Milwaukee.**—Milwaukee, according to a statistician of the Wisconsin Public Utilities Information Bureau, is rapidly becoming an electrical city. It is neck and neck with Pittsburgh in the use of the electric furnace for steel making and other metal melting and is a large user of electrical energy for japanning and similar purposes. To meet the demands of the city and the surrounding territory, including Racine, Kenosha and other places within a radius of about 40 miles, there is now a minimum generating capacity of some 176,700 kw., to which may be added 10,000 kw. received from the Wisconsin River hydroelectric plants. To this will be added by the end of the year 30,000 kw. more in the unit now being installed in the big plant at Lakeside by the Milwaukee Electric Railway & Light Company. It is predicted that within a short time the electrical energy generated in the steam plants in and close to Milwaukee will exceed the total of the big water-power developments now under way in

the state, which is put at 353,000 hp. This estimate does not include any of the industrial plants still in existence.

**New Jersey Utilities to Combine.**—The Morris & Somerset Electric Company, the Commonwealth Electric Company and the Lakewood & Coast Electric Company are to combine under the name of the Jersey Central Power & Light Corporation. New financing will consist of $3,500,000 in first-lien 6½ per cent bonds.

**Radio Signals of Standard Frequency.**—Radio signals of standard frequency are now being transmitted from the Bureau of Standards at Washington. These standard frequency signals are intended to be used for standardizing wavemeters and adjusting transmitting and receiving apparatus. The proper adjustment of such apparatus is particularly important in connection with the reallocation of waves as recommended by the second radio conference held in Washington in March. Methods for receiving and utilizing these signals for wavemeter calibration have been published in the *Radio Service Bulletin*, and more detailed information may be obtained upon application to the Bureau of Standards. The announced values of these signals are accurate to better than three-tenths of 1 per cent.

**Cities Service Company in April.**—The statement of earnings of Cities Service Company for the twelve months ended April 30 showed gross earnings amounting to $16,003,548, which compared with $12,688,908 in the corresponding period of 1922. Net earnings were $15,528,247, as compared with $12,229,894, and net to stock was $12,989,007, as compared with $10,086,102. Net to common stock and reserves amounted to $8,050,881, as compared with $5,205,591 in the preceding twelve months. In the twelve-month period the preferred dividend was earned 2.63 times, as compared with 2.07 times in the twelve months ended with April 30, 1922, while the percentage earned on the average amount of common stock outstanding was 17.28 as against 11.20. Net to common stock and reserves for the month of April, 1923, was $1,043,426, which compared with $752,462 earned in April, 1922.

**Engineers to Study New Power Codes.**—Two power test codes, part of a group of nineteen being framed as aids to industry by 125 engineers, scientists and educators under the auspices of the American Society of Mechanical Engineers, will be discussed at a public hearing in connection with the society's spring meeting at Montreal next week. For more than four years nineteen committees, representing practically every industrial center, have been engaged in this work, directed by a main committee of twenty-five. One of the codes to be considered at Montreal relates to instruments and apparatus for measuring physical and chemical quantities in connection with tests of power equipment. The second code deals with internal-combustion engines of all forms, but is limited to the engines alone. Sizes of internal-combustion engines coming within this code range from one to several thousand horsepower.

**Electricity in the Poultry Yard.**—The Department of Agriculture is officially advising poultry raisers of the benefits to be gained from electricity in their business. It recounts an experiment in which one 75-watt lamp was in a room housing fifty pullets for two and one-half hours daily for 140 days with excellent results. It was turned on automatically at 4.30 a.m. and allowed to run until daylight. When the light is used in the evening arrangement has to be made for dimming before the current is switched off entirely so that the hens will go to roost before total darkness prevails. The department also points out that a good way to keep water in the poultry yard from freezing during the winter is to cover a carbon-filament lamp with black cloth and submerge it in the drinking pan.

**Germany Turning to Large and Interconnected Plants.**—Existing conditions in Germany are forcing out of business the coal-burning power plants with high operating costs, according to a report recently received by the Department of Commerce. Such stations have had great difficulty in obtaining the necessary credit for extensions and new equipment. Difficulty in procuring coal has added to their troubles. The result has been a further concentration of power production in the larger and more efficient stations. This is stimulating interconnection, and as a result lower rates to consumers have been made possible. A very lively interest is being manifested in the conversion of some of the larger central stations from steam power to water power. The matter has been taken up with both German and foreign bankers, but because of the very large amounts involved no great amount of encouragement has been forthcoming.

# Associations and Societies

**Taylor Society's June Meeting.**—The Taylor Society, which has for its objects the promotion of the science and the art of administration and of management, will meet at the Hotel Onondaga, Syracuse, on June 7, 8 and 9 to listen to papers and inspect industrial planning departments.

**Baltimore Section, A. I. E. E.**—Prof. W. B. Kouwenhoven was elected chairman of this section at its meeting last week, F. T. Leilich vice-chairman and R. T. Greer secretary. Earl A. Anderson of the National Lamp Works spoke on illumination in office and factory buildings.

**Cheyenne Electric Club Organized.**—Electrical men in Cheyenne, Wyo., have recently completed the organization of the Cheyenne Electric Club with the purpose of bettering the electrical industry in the Wyoming city. The members will discuss electrical problems and educate the public concerning them.

**National Association of Manufacturers Elects Officers.**—John E. Edgerton of Lebanon, Tenn., president of the National Association of Manufacturers, was re-elected to office for another year in the closing session of the New York convention last week, as were also Henry Abbott of New York City, treasurer, George S. Boudinot, secretary, and Earl Constantine, New York City, assistant to the president.

**Nominations for Governors of A. M. E. S.**—In accordance with the constitution the nominating committee of the Associated Manufacturers of Electrical Supplies has selected as nominees for vacancies on the board of governors, to be voted upon at the annual meeting of the association during the week of June 25, S. B. Condit of the Condit Electrical Manufacturing Company, Boston; A. G. Kimball of Landers, Frary & Clark, New Britain, Conn.; W. W. Mumma of the Robbins & Myers Company, Springfield, Ohio; M. C. Rypinski of C. Brandes, Inc., New York City, and F. T. Wheeler of the Trumbull Electric Manufacturing Company, Plainville, Conn.

---

## Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

Westinghouse Agent-Jobbers' Association—Hot Springs, Va., May 28-June 2.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

California State Association of Electrical Contractors and Dealers—Dorner Lake, Cal., June 9-16.

Electric Power Club—Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

North Central Division, N. E. L. A.—Minneapolis, June 20-22. H. E. Young, Minneapolis General Electric Company.

Society for the Promotion of Engineering Education—Ithaca, N. Y., June 20-22. F. L. Bishop, University of Pittsburgh.

Canadian Electrical Association—Montreal, June 20-23. Louis Kon, 65 McGill College Ave., Montreal.

American Institute of Electrical Engineers—Annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Oct. 2-5. F. L. Hutchinson, 33 West 39th St., New York.

American Society for Testing Materials—Atlantic City, June 25-29.

Iowa Section, N. E. L. A.—Mason City, June 26-29. M. A. Linn, Des Moines Electric Co., Des Moines.

Associated Manufacturers of Electrical Supplies—New London, Conn., June 26-29. Frederic Nicholas, 30 East 42d St., New York.

National Council Lighting Fixture Manufacturers—Buffalo, June 26-28. C. H. Hofrichter, 233 Gordon Square Bldg., Cleveland.

Northwest Electric Light and Power Association—Seattle, June 27-30. G. E. Quinan, 204 Electric Bldg., Seattle.

Ohio Electric Light Association—Cedar Point, July 10-13. D. L. Gaskill, Greenville.

New England Division, N. E. L. A.—Swampscott, Mass., Sept. 6-8. Miss O. A. Bursiel, 149 Tremont St., Boston.

Michigan Electric Light Association—Grand Rapids, Sept. 11-13. Herbert Silvester, Detroit Edison Co., Ann Arbor.

Rocky Mountain Division, N. E. L. A.—Glenwood Springs, Col., Sept. 17-19. O. A. Weller, 900 15th St., Denver.

Association of Iron and Steel Electrical Engineers—Buffalo, Sept. 24-28. J. F. Kelly, 513 Empire Bldg., Pittsburgh.

## Recent Court Decisions

**Supreme Court Again Finds that Cost of Reproduction New Must Be Considered in Valuation Proceedings.**—Rates for public service corporations which fail to take into consideration the cost of reproduction at prevailing prices were disapproved by a decision rendered by the United States Supreme Court this week in the case of the Southwestern Bell Telephone Company vs. Missouri Public Service Commission. "It is impossible," the opinion said, "to ascertain what will amount to a fair return upon properties devoted to public service without giving consideration to the cost of labor, supplies, etc., at the time the investigation is made. An honest and intelligent forecast of probable future values, made upon a view of all the relevant circumstances, is essential. If the highly important element of present costs is wholly disregarded, such a forecast becomes impossible. Estimates for tomorrow cannot ignore prices of today." It must never be forgotten, the court added, "that while the state may regulate with a view to enforcing reasonable rates and charges, it is not the owner of the property of public utility companies and is not clothed with the general power of management incident to ownership." A separate opinion by Justice Brandeis, in which Justice Holmes concurred, asserted that advocates of reproduction cost as an element of rate making would find its application harmful to the public utilities when the cost of material and wages was lower. Justice Brandeis suggested as a preferable basis the money invested in the enterprise. Urging the court to "lay down a rule which will establish such a rate basis and such a measure of the rate of return deemed fair," he criticised his colleagues for leaving many of the elements to be determined by the opinion of experts, instead of making rates dependent upon ascertainable facts. While agreeing that reproduction costs as an essential element in rate making are better than the old tests—selling price or net earnings—the minority insisted that "where the financing has been proper the cost to the utility of the capital required to construct, equip and operate its plant should measure the rate of return which the Constitution guarantees opportunity to earn." Such a rule, it added, would make rates based on facts and not on opinion. Under the rule the court adopted, the value for rate-making purposes, the minority insisted, "must ever be an unstable factor." The public utilities would try to make the court adopt reproduction cost or prudent investment as the measure of rates according to which was the higher at the time that valuation proceedings were under way.

**Milldam Owner Willfully Diverting Water of Natural Stream Liable for Damages.**—In a suit brought by one McKee against the Nebraska Gas & Electric Company damages were sought on account of the action of the company in diverting the waters of the Cedar River at Fullerton in order to save its power plant, threatened with destruction by a rise in the river, from which by means of a dam the company derived power to operate its turbine wheel. As a result of this change in the course of the stream the plaintiff claimed that heavy rains had on these occasions caused his land to be flooded, live stock to be drowned and crops to be destroyed. The Supreme Court of Nebraska sustained the trial court in finding for the plaintiff, maintaining that the good faith of the defendant in believing its action necessary to preserve its own property and the absence of negligence or malice could not absolve it from the liability to recompense those whose property had been damaged by its course. (193 N. W. 106.)*

## Commission Rulings

**Savings from Improvement in Street Lamps Divided Equally Between Utility and Municipality.**—A franchise granted the Marshall Ice & Power Company by Martinsville, Ill., confused watts and candlepower in such a way that the company stood to make a considerable saving on account of the improvement in the art of lighting. The Illinois Commerce Commission ordered that the saving should be divided between the utility and the municipality, holding that neither was responsible for the fact that it is possible "to secure the same quantity of light from the expenditure of 29 per cent less electrical energy."

**Reproduction-Cost Theory Criticised.**—In its valuation of the waterworks properties of the Newport News Light & Water Company, the Virginia State Corporation Commission criticised the theory of evaluating a property strictly according to reproduction cost. "Counsel for the city," said the commission, "comment on the fact that the strict reproduction-cost theory, vigorously opposed by railways and public utilities in the days when such cost was less than actual investment, has come into favor in times of high levels of unit prices. It is true that public regulation is a growing science and must change with the changing times. While some of the old methods of regulation may appear as dead as Tut-ankh-Amen, their relics may, in the cycles of time, again become the model of fashion and the object of public approval. . . . The commission believes that in this as in previous cases the determination should begin with pre-war values and appreciate them a reasonable percentage, so as to allow for higher price levels. To the sum thus arrived at there must be added the actual money since pre-war days honestly and prudently expended in the public service."

**Has a Public Utility Vested Rights?**—In its decision holding the Terre Haute, Indianapolis & Eastern Traction Company to be an existing and not a new light and power utility, and therefore entitled to extend its service and operate as a general electricity supply company within the city of Indianapolis, despite the protests of the two central-station companies established there (ELECTRICAL WORLD, April 21, page 942), the Indiana Public Service Commission made some general observations on the standing of public utilities in a community as follows: "Has a utility any vested right in a community? Can a utility claim a vested right in the increase of a city which has doubled its population within a short time? If a city extends its corporation lines, taking in a town having a utility operating efficiently within it, can the town utility be excluded at the request of the city utility? Can a utility in one town or community be excluded from rendering service in another? What influence do arbitrary lines bounding cities, towns and townships have on conditions affecting utility service? Would not the answer in each case depend upon the conditions in each community considered? Is there any other test that can be applied to all situations? Is it not *the* test? Those who embark in the operation of public utilities must, of necessity, be subjected to certain hazards of the business, the same as operators in other lines of commercial activity, and when the interest of any utility runs counter to the general public interest the utility must submit and the general public welfare must prevail, and this is true whether the condition is the result of any act of omission of the utility or not, because of the recognized principle that the interest of society in general outweighs the interest of any member or portion thereof, and that is the basic principle of laws regulating public utilities everywhere. Such laws, including the one under which this commission is operating, are enacted in the interest of the public welfare and not in the interest of the public utilities, except in cases where the protection against competition or confiscation works to the best interests of the general public, which involves, not cheap rates temporarily, but standard service for a reasonable remuneration for present and future needs, which includes opportunity, ability, financial support and readiness to render the required service. The commission is not unmindful of the fact that it is to the best interest of the public that utilities be protected against confiscation and destructive competition, and these considerations are constantly kept in mind."

# Men of the Industry

**Changes in Personnel**
**Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry**

## C. H. Howell Goes to Atlantic City

C. H. Howell, general manager and vice-president of the Ohio Service Company, has been transferred to Atlantic City, N. J., to take charge of the properties of the American Gas & Electric Company in that state. Mr. Howell had been stationed in Coshocton since 1912, when he became manager of what was at that time the Coshocton Light & Heating Company. Later other properties in that section of Ohio were merged into a single corporation, the present Ohio Service Company, and Mr. Howell was made manager. He is a past-president of the Ohio Electric Light Association and has a host of friends in electrical circles in that state.

**Julian C. Smith** has been elected president of the Quebec Railway, Light, Heat & Power Company, succeeding E. A. Robert.

**Dr. Emmanuel de Margerie,** French exchange professor to the United States, was the guest of honor at a farewell luncheon given on May 18 at the Harvard Club, New York. Two hundred engineers attended and representatives of many of the leading colleges and universities were present. Dr. de Margerie has just finished a year of lecturing at Columbia, Cornell, Harvard, Johns Hopkins, Yale and Pennsylvania.

**O. M. Drischel,** manager of the Marion division of the Indiana General Service Company, has been appointed general manager of the company. Mr. Drischel has been associated with the company since its organization. The following changes are also announced: Roy Thurman becomes manager of the Muncie division, replacing O. E. Halderman, who goes to one of the Ohio properties, and T. M. Parker of Marion is transferred to the Hartford City (Ind.) division as manager, succeeding Henry Wallsmith, who is transferred to Benton Harbor, Mich.

**E. P. Peck,** general superintendent of the electrical department of the Utica (N. Y.) Gas & Electric Company, was unanimously elected chairman of the Electrical Section of the Empire State Gas & Electric Association at its meeting in Utica on May 18. Ever since going to New York State from the Georgia Railway & Power Company in 1919 Mr. Peck has been very active in the association. Most prominent among his recent committee activities have been the recommendations for standardization of transmission-line construction and his work as chairman of a committee that is endeavoring to solve the problems of greater interconnection of electric service systems within the state and in the adjoining territory. In the South, where Mr. Peck was superintendent of operation, tests and repairs, he became prominent for his original investigations and development work.

## Edmund Lang Elected President of Crocker-Wheeler

Edmund Lang, who was recently elected president of the Crocker-Wheeler Company, Ampere, N. J., succeeding the late Dr. Schuyler Skaats Wheeler, has been associated with the company since 1909, when he was selected to handle the many intricacies of the repair department, which had just been organized as an entirely separate unit from the main shop. His thorough and successful work so impressed the officers of the organization that in 1911 he was made purchasing agent.

EDMUND LANG

Two years later Mr. Lang was elected secretary of the company, and in 1915, when the office of sales manager became vacant, he was chosen to fill this post. Subsequently he was elected a director, and in 1919 he became senior vice-president and a member of the company's executive committee, devoting considerable time to administrative matters.

Mr. Lang was born in New York City in 1880 and inherited from his father, Charles F. Lang, who was for many years a manufacturer of steam engines and auxiliary machinery, a love of mechanics and engineering. He became associated with Arthur Schroeder, the New York sales agent for the Ætna Standard Iron & Steel Company of Martins Ferry, Ohio, in 1894, and in 1900 he entered the New York sales office of the American Steel Hoop Company, which later became a subsidiary of the United States Steel Corporation. When the sales department was removed to Pittsburgh Mr. Lang joined the force of Westinghouse, Church, Kerr & Company and later allied himself with the Keystone Electric Company, where he gained intimate knowledge of estimating and buying for the contracting and engineering branch of the business. In 1903 he joined the Wheeler Condenser & Engineering Company, but his desire for broadening his experience led him to organize in 1907 the Universal Engineering Company to build or reconstruct power and heating plants. Mr. Lang is a member of the Engineers' Club and is also vice-president and a director of the Curtis Gas Engine Company of New York.

**D. W. Roper,** underground cable superintendent of the Commonwealth Edison Company, sailed for Europe on May 19, to spend four months studying the foreign methods of cable manufacture and high-voltage distribution systems. His itinerary will include England, France, Italy and possibly Scandinavia and Germany. Other engineers of the company who sailed with Mr. Roper for the purpose of investigating European power-plant layouts were Secor Cunningham, Jr., B. G. Jamieson, Samuel Insull, Jr., and F. E. Goodnow of the Public Service Company of Northern Illinois.

**George A. Iler,** an electrical engineer of wide experience and a pioneer in the development of radio engineering, has been appointed electrical engineer of the Pennsylvania-Ohio electrical system at Wheeling, W. Va., succeeding C. A. Harrington, who recently resigned. Mr. Iler goes to Wheeling from Atlanta, where for the last year he was radio engineer for the Atlanta *Journal*, constructing and operating the big broadcasting plant of that paper. Mr. Iler is an Ohioan by birth and served for a time as electrician in the United States Navy. Following his naval service he devoted his energies to electrical work in various parts of the country in charge of construction and operation of power generating plants, transmission systems and general electrical engineering work, completing his education by a post-graduate course at the Georgia Institute of Technology. Among other important work in which he has been engaged are the building and operating of the first power-transmission lines for the General Electric Company in the New River coal district, W. Va., and the early application of electrical power to mining projects there, as well as the construction of the 100,000-hp. hydro-electric power plant at Atlanta for the Georgia Railway & Power Company. He early gave attention to the development of radio and for several years he was connected as consulting radio engineer with the Westinghouse Electric & Manufacturing Company.

# Manufacturing and Markets

Devoted to the Discussion of Business and Economic Problems of the Producer and Distributor, with Market Reports, Trade Activities, Foreign and Construction News

## Agencies Promoting Standardization

**An Outline of Association and Government Efforts to Stop Waste Throughout the World—Commercial and Engineering Sides Are Discussed**

By C. E. Skinner
Manager of Research Department,
Westinghouse Electric & Manufacturing Company, Pittsburgh

MANY millions of dollars could be saved to the consuming public in the United States each year by proper standardization and simplification. Much has been done along this line and many agencies are at work, but the field is as yet little more than touched. Proper standardization requires that the standards adopted shall be satisfactory to all parties at interest and that progress be not arrested by such standardization. Very much of the standardization already accomplished has been a very great aid to progress, and further standardization and simplification can and will accomplish still greater things.

C. E. Skinner

In the electrical business we will probably never make our transformers or motors or generators to exact duplicate specifications, but there has been a constant trend to greater uniformity in rating and to the standardization of those things which tend to make apparatus interchangeable. The very rapid increase in the application of electricity to new fields requires an added complexity of apparatus to meet these demands. The stabilization of applications in many fields, the necessity for quantity production and the cheapening of the product are leading to the use of standards wherever standards can be applied.

The proper balance between standardization and development along new lines is very difficult to strike. Too much standardization tends to delay development; too much development along different lines in an industry tends to complication and excessive costs. The more rapid the development, the more difficult to adhere to standards and the greater difficulty of effecting standardization

The United States is pre-eminently the leader in machine-made products. This is due to the necessity for quantity production along so many lines, to the relatively high cost of labor, and to what has sometimes been described as our Yankee ingenuity in the development of such machine methods. From the standpoint of labor conditions, we face competition at the present time more difficult than ever before. The answer to this competition is quantity production and machine methods. These depend primarily on standardization. This explains, in some measure, the nation-wide movement evident in so many lines looking toward standardization. It may be profitable to review some of the agencies at work, their accomplishments and promise for the future:

**Standards Committee, A. I. E. E.**—Among the early movements for national standardization in the United States was the organization of a standards committee of the American Institute of Electrical Engineers. This standards committee has confined itself very largely to the standardization of those fundamentals underlying the design and performance of electrical machinery and has concerned itself little or not at all with that kind of standardization which results in duplicate parts and which is usually known as dimensional standardization. The work of the committee has been continued through a period of extremely rapid development in the electrical industry, and the committee has been quick to make those changes which have been necessitated by the growth in knowledge of the subject and in the development of the industry. Indeed, the standards committee work has brought about very important researches intended to settle points of dispute and points on which there was not adequate knowledge. A large volume of standards has been produced, and these standards are very closely followed in the manufacture of most electrical apparatus in the United States today. Its work has had an international bearing. It is substantially in accord with the electrical standardization in other countries.

**American Society for Testing Materials.**—One of the most active organizations in standardization in the United States is the American Society for Testing Materials. This society has to do with the standards for testing materials and the production of specifications which may be used in the purchase of materials. In the formulation of its specifications the society has from the very start followed the principle that both the producer and consumer, as well as independent interests, must be satisfied with any specification before it is adopted. As a result, many of the specifications now issued have required years of patient effort to bring all parties into harmony, and numbers of them have gone through considerable periods of probation before they were made final. Furthermore, provision is made for revision, whenever such revision may become necessary owing to change in the art or change in requirements.

### Quality Standards Raised

As a result, purchasers of many kinds of materials utilize these specifications without change or they embody their requirements in their own purchase specifications. It is impossible to evaluate the influence for good which these specifications have had on industry generally. They have resulted in better materials, better understandings between producers and consumers; they have assisted in bringing about quantity production, and they have generally raised the standard of quality of the materials used in the particular industry for which the specifications are written.

**Society of Automotive Engineers.**—Perhaps in no other industry have both dimensional standardization and quality standardization been so essential to progress as in the automobile industry. Dimensional standardization was required because of the very large number of manufacturers and the enormous quantity of small parts required, such as screws, bolts, nuts, etc. The necessity for the production of a machine

which would stand the service required of an automobile and at the same time have minimum weight has required high-grade materials to a greater extent perhaps than any other device. It is certainly true that this standardization work has not been a hindrance in the development of new types of automobiles.

**American Society of Mechanical Engineers.**—The standards work of the American Society of Mechanical Engineers has been perhaps less extensive than that of the organizations already mentioned, but it has accomplished a great deal in the way of standardization. The Boiler Code of the American Society of Mechanical Engineers is the standard not only in the United States but in a number of other countries as well. The standards for machine screws have been quite generally adopted, and this society has on hand a number of other projects which will be of greater value when completed.

**Electric Power Club.**—Another organization which has been working along somewhat different lines is the Electric Power Club. This organization, composed entirely of manufacturers, has standardized more along commercial lines. It has dealt with sizes, ratings, interchangeability, testing and performance of electrical apparatus. The performance specifications of the Power Club have been very largely based on the standards of the American Institute of Electrical Engineers, the latter in the past dealing with what might be called engineering standards and the former with commercial standards. These two organizations are now working in the closest harmony in the further production of standards with regard to the rating of electrical machinery.

**National Fire Protection Association.**—The National Electrical Code, developed under the auspices of the National Fire Protection Association and with the co-operation of underwriters, contractors, manufacturers and interested organizations generally, is really a set of standards for the installation and use of electrical equipment to provide that such installations shall entail a minimum fire hazard. These standards are now generally recognized throughout the United States as satisfactory, and they have been adopted by many cities as municipal standards.

**United States Bureau of Standards.**—The Bureau of Standards was established under an act of Congress on March 1, 1901, and Section II of this act reads as follows: "That the functions of the bureau shall consist in the custody of the standards; the comparison of the standards used in scientific investigations, engineering, manufacturing, commerce, and educational institutions with the standards adopted or recognized by the government; the construction, when necessary, of standards, their multiples and subdivisions; the testing and calibration of standard measuring apparatus; the solution of problems which arise in connection with standards; the determination of physical constants and the properties of materials, when such data are of great importance to scientific or manufacturing interest and are not to be obtained of sufficient accuracy elsewhere."

One of the activities of the Bureau of Standards has resulted in the production of what is known as the National Electrical Safety Code. This is a set of standards which deals with the life hazard of electrical installations, just as the National Electrical Code deals with the fire hazard. This code is mentioned on account of its importance to the electrical industry and on account of the fact that it illustrates a type of standardization which is receiving a very great deal of attention throughout the country today.

**Division of Simplified Practice.**—The Department of Commerce, under its present Secretary, has organized what is known as the Division of Simplified Practice. It is recognized that many of our industries and many more of our businesses are suffering from too great a variety of almost every article of commerce in this country. It is the object of the Division of Simplified Practice to bring about, through agreement of the parties interested, a radical reduction in the sizes and varieties of commodities manufactured and sold in the United States.

### A Point for Co-operation

THIS very complete account of the accomplishments and future purposes of the agencies that are carrying on the work of standardization of industries in all parts of the world is particularly interesting to every division of the electrical industry, which, as shown by this article, is with the leaders in eliminating waste for both the manufacturer and consumer.

During the last two years, the period of most interest in carrying on the work of these associations and government bureaus, progress in eliminating excess varieties has been hindered by the fear of manufacturers that others making their lines would not follow suit and that orders would be lost in the markets where many unusual demands are made. It is hoped that this review of what all industries are doing to reduce waste of effort and materials will do much to direct the minds of the manufacturers, jobbers and purchasing agents along the straight road that leads to the storehouse of standardized products.

The above list comprises only a few of the bodies of national scope engaged in standardization for the industrial world. They should serve to illustrate both the tremendous interest in standardization at the present time and the evident value that such standardization must possess to industry in general.

While the organizations described are all of national scope, there has been no organization until recently which could rightly issue standards with the stamp of approval in such a way that they might truly be called American standards. This fact has been very forcibly brought to the attention of delegates who have attended various international meetings with the view of international standardization. The desirability for some organization which could put its stamp of approval on specifications and standards in such a way that they could be truly denominated as American specifications or American Standards led the standards committee of the American Institute of Electrical Engineers to suggest the organization of what has since become the American Engineering Standards Committee.

**American Engineering Standards Committee.**—This committee was organized by the four founder societies, i.e., the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, together with the American Society for Testing Materials.

The organization work occupied approximately two years, and the organization committee attempted very carefully to go into every phase of the question so that the final organization might be truly representative of every branch of engineering which had to do with standardization. Provision was made for bringing into membership of the society all organizations which were of national scope and which were interested in engineering standardization. At the time of the organization of the A. E. S. C. there were more than one hundred organizations publishing engineering standards, most of which were formulated without systematic methods of co-operation between the organizations concerned. At the present time more than 160 organizations are actively co-operating in the work of the committee, having appointed accredited representatives on sectional committees.

For some years the unification and approval of existing standards will necessarily form an important part of the committee's work. The rules of procedure provide that: "Any standards adopted or in process prior to Jan. 1, 1920, may be approved by the main committee if, in its opinion, the standard has been developed by an organization and procedure substantially in conformity with these rules, or if it has, by actual practice, proved its right to become a standard," without the standards having gone through the machinery of a sectional committee. While the most satisfactory way of determining the status which a standard has in industry is to submit it to a duly organized sectional committee, there are cases in which such a full procedure would be considered a hardship. Hence the provision referred to. Before acting upon the approval of a standard submitted under this provision, a notice of its submission is sent to the technical press and to the industrial associations and technical bodies interested, requesting information as to the standard in meeting the needs of industry, and the matter is referred to a special committee for investigation. This special committee usually contains accredited representatives of those bodies which are most concerned with the standard, in order that the spirit of the sectional committee method may be carried out.

**Federal Specifications Board.**—This Federal Specifications Board has been set up as a part of the general scheme to promote economy and efficiency in

the routine business of the federal government. This board was organized under the authority of Circular 42, Bureau of the Budget, dated Oct. 10, 1921, in which it was stated that the establishment of the board was "for the purpose of co-ordination and economy in the procurement of materials and services used by the government under specifications prepared by the various branches thereof, to avoid duplication of effort and for the better utilization of industries."

The duties of the Federal Specifications Board are to compile and adopt standard specifications for materials and services and to bring the government specifications into harmony with the best commercial practice wherever conditions permit, bearing in mind the desirability of broadening the field of supply. Its work is being done under the leadership of the Bureau of Standards, and each interested department of the government has designated a representative to serve on the board. The circular establishing the Federal Specifications Board states that the specifications adopted and promulgated by the board shall be binding upon all and govern all departments and independent establishments of the federal government. These instructions were issued by the Director of the Bureau of the Budget, by the direction of the President.

The subject of standardization is receiving very serious consideration in practically all industrial countries. At the present time there are fourteen national standardizing bodies, including the American Engineering Standards Committee, in the United States. The countries having these national standardizing bodies are Austria, Belgium, Canada, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Japan, Norway, Sweden, Switzerland and the United States.

The oldest national standardizing body is that of Great Britain and is known as the British Engineering Standards Association, established in 1901. This association has to its credit the largest number of projects completed and probably the largest number of projects under way. It has more than twenty-five sectional committees with more than three hundred sub-committees, with a membership of over one thousand four hundred individuals at work. The work of this association goes into every branch of industry, but up to date has not included work on safety codes, which is now becoming a considerable part of the work of the American Engineering Standards Committee.

Perhaps the next country in order of importance so far as its accomplishment in the line of standardization is concerned is Germany. The organization here is along a line somewhat simliar to that of the other countries, and during the last few years a great deal has been accomplished which will be of aid to German industry. Of interest to electrical engineers is the fact that in a number of lines standard performances and standard connections have been adopted, so that transformers, for example, of any make will run in parallel with similar transformers of any other make. Voltage taps of all makes are the same.

### INTERNATIONAL PROGRESS

Very serious efforts are being made to accomplish international standardization in many fields.

**International Electrotechnical Commission.**—The oldest and the most experienced of the international bodies whose primary purpose is industrial standardization is the International Electrotechnical Commission, which was organized in 1906 as an outcome of the meeting of the electrical engineers of the world at the St. Louis Exposition in 1903. The International Electrotechnical Commission consists of national committees in each of twenty-six different countries. The work is done by what is known as advisory committees, and decisions are reached at plenary meetings of the commission which are held from time to time.

The influence of the standards committee of the American Institute of Electrical Engineers has been a considerable factor in the past work of the commission, and the American standards are now in very substantial agreement with the international standards so far adopted by the commission. A recent meeting of the advisory committees was held in Geneva, Switzerland, at which meeting there were twelve nations represented, and a total of more than fifty delegates. The chief subjects discussed at this meeting were the basis of rating for general-purpose motors of the open type, standard transmission voltages, factors involved in the rating of water-cooled transformers, abbreviations, symbols and nomenclature, and standard screw plugs and sockets for incandescent lamps.

# Business Conditions

**A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand**

TAKING the electrical market as a whole, it is seen that jobbers and contractor-dealers are considering with less indifference the certain warnings of manufacturers made two months ago when prices were increasing on a rising market. Although a few price increases were made in the market last week, they are of an easier sort and are due mostly to the labor and raw-material situations. Conditions in the market are said to be of a more healthy state than two months ago, and this is certainly true of six months ago.

## Eastern Sections Are Buying in More Conservative Way

IN THE Eastern sections orders to electrical manufacturers, jobbers and retailers continue to flow in fair volume. Less buoyancy is apparent and commitments are a little more conservative, but widespread agreement exists as to the healthy state of the market.

In executive circles the feeling is general that business will be excellent for the rest of the year at least. The buyer is conservative in attitude, and recent tendencies toward inflation appear to have been checked. Price movements are spotty. An advance in direct-current motors amounting to about 10 per cent was scheduled for the first of the week and fuse plugs rose about 8 per cent last week. Brass dropped about a cent a pound last week and copper softened somewhat. Rail deliveries are below desirable standards, but embargoes are being relaxed and road-truck service is improving.

Manufacturers are working close to capacity. In New England the building contract total for the latest reported week exceeded $8,000,000, the best for this week in two decades. Conferences looking toward settling prevalent disputes in the building industry at Boston were scheduled for this week. Retail sales in the electrical field are in excellent volume, interest in ranges showing response to good merchandis-

## Comparative Prices of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | $0.034 | $0.0326 | $0.0236 |
| Cold finished shafting, per lb. | 0.042 | 0.0406 | 0.1466 |
| Brass rods, per lb. | 0.1850 | 0.1913 | 0.15 |
| Solder (half and half), por lb. | 0.2862 | 0.30 | 0.21 |
| Cotton waste, per lb. | 0.1231 | 0.1231 | 0.104 |
| Washers, cast iron (½-in.), per 100 lb. | 4.66 | 4.66 | 4.00 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 2.96 | 3.11 |
| Machine oil, per gal. | 0.349 | 0.349 | 0.40 |
| Belting, leather, medium, off list | 42% | 42% | 48½% |
| Machine bolts, up to 1-in. x 30-in., off list | 44¼% | 44¼% | 62½% |

ing methods. Cool weather has hurt the early spring fan trade. Lamps are in enormous demand and hollow ware is moving well. Collections throughout the eastern part of the country are showing an improvement.

## Neglecting Foreign Trade When Domestic Market Is Booming

After having captured considerable foreign trade, American electrical manufacturers are allowing it to get away from them while they cater to the domestic market, which for the present is more attractive. This turn in merchandising is true of most other industries of the United States, reports to the Department of Commerce from a large number of countries indicating that American exporters are neglecting their foreign business to a considerable degree.

Since the war upset the world's trade the average American exporter has been playing the flirt with foreign markets. For a time every attention will be given a foreign buyer and then without warning he will be jilted. Just as the coquette usually ends up an old maid, it is feared that many markets will be lost irretrievably if the present practices continue.

Largely as a result of fortuitous circumstances, the United States has built up an important foreign business. While favorable conditions were responsible for inducing American electrical manufacturers to go into foreign markets, their activities in that connection represent a large investment. Not only is this investment being jeopardized by the present business policies of many exporters, but it is sealing the way against any retracing of steps when domestic demand for electrical products begins to fall off.

Officials of the Department of Commerce are urging that a fair distribution of available stocks be made among all customers. If there is to be any favoritism shown, it should be in favor of the foreign market. American manufacturers and other exporters, it is pointed out, would be well advised in taking a leaf from the German book. Germany, and to a less extent England, fills foreign orders first. These countries are in a position to satisfy their domestic customers later if the latter

## Exports of Lighting Outfits, Batteries, Rectifiers,

should be displeased with deliveries to them. Concrete information is at hand from a hundred sources to indicate that foreign markets are being neglected by America. The situation applies to all lines and is not confined to the electrical industry. It is regarded as of sufficient seriousness to require the most energetic efforts to effect a remedy while there still is time.

## A Normal Week Is Reported in Chicago

CHICAGO jobbers and dealers report a normal week of electrical business. No important changes in price were announced, except an increase of 7 per cent on 1¼-in x 8-in. standard-grade locust pins and a 5 per cent increase on all wood-top pins. Plug fuses have advanced 6 per cent. High-tension equipment sales are keeping up to their previous standard, manufacturers reporting good business and sales to several large stations being made. Pole-line hardware manufacturers had a good week, with no advance in prices at this time, although one is expected shortly.

Numerous selling drives and advertising campaigns have been started on socket devices, such as flat-irons, vacuum cleaners and washing machines, this week. Dealers state that the sale of these commodities remains about the same, with no exceptional sales reported. Tape manufacturers assert that tape is being bought in considerable quantities and that the price will remain firm until the first of June.

## The Metal Market

COPPER is more steady and is holding its own at the 15.50-cent level. The volume of business transacted during the week was small. The more important producers are virtually out of the market, these selling only an occasional lot to regular customers.

NEW YORK METAL MARKET PRICES

| | May 16, 1923 Cents per Pound | May 23, 192[illegible] Cents per Pound |
|---|---|---|
| Copper, electrolytic | 15.25 | 15.50 |
| Lead, Am. S. & R. price | 7.25 | 7.25 |
| Antimony | 8.00 | 8.00 |
| Nickel, ingot | 28.00–30.00 | 28.00 to 30.0[illegible] |
| Zinc, spot | 7.15 | 6.60 |
| Tin, Straits | 45.00 | 43.00 |
| Aluminum, 98 to 99 per cent | 26.00 | 26.00 to 27.0[illegible] |

### April National Delinquent Accounts Were Fewer

FIVE of the six territories reporting for April to the National Electrical Credit Association announce a smaller number of delinquent accounts over March, 1923, and April, 1922. In the Chicago central division section the April, 1923, accounts numbered 794, against 993 for March, 1923, although the average amount for this same period was $139.96, against $131.49 for March, 1923. New York reported 422 delinquent accounts, against 460 in April, 1922, but the average amount increased $28 per account.

Philadelphia's account went from 232 for April, 1922, to 241 in April 1923, but lowered the average amount from $148.51 to $145.60. In both the New England and the Pacific Coast territories the number of accounts for March and April this year has been decreasing. The total number and amount of delinquent accounts follow:

DELINQUENT ACCOUNTS IN APRIL

| Branch and Month | Number of Delinquent Accounts Reported | Total Amount | Average Amount |
|---|---|---|---|
| Central Division: | | | |
| March, 1922.. | 978 | $98,569.53 | $100.79 |
| March, 1923.. | 993 | 130,571.90 | 131.49 |
| April, 1922.. | 799 | 87,991.88 | 110.13 |
| April, 1923.. | 794 | 111,130.28 | 139.96 |
| New York: | | | |
| March, 1922.. | 643 | 72,843.00 | 113.00 |
| March, 1923.. | 584 | 73,655.00 | 126.00 |
| April, 1922.. | 460 | 56,616.00 | 123.00 |
| April, 1923.. | 422 | 63,771.00 | 151.00 |
| Philadelphia: | | | |
| March, 1922.. | 277 | 28,095.09 | 101.42 |
| March, 1923.. | 204 | 26,386.27 | 129.34 |
| April, 1922.. | 232 | 34,454.70 | 148.51 |
| April, 1923.. | 241 | 35,099.19 | 145.60 |
| New England: | | | |
| March, 1922.. | 129 | 11,170.85 | 86.59 |
| March, 1923.. | 60 | 4,782.71 | 79.71 |
| April, 1922.. | 68 | 7,128.00 | 104.82 |
| April, 1923.. | 44 | 7,979.04 | 181.34 |
| Pacific Coast: | | | |
| March, 1922.. | 18 | 2,681.95 | 148.09 |
| March, 1923.. | 48 | 7,522.26 | 156.92 |
| April, 1922.. | 25 | 3,594.67 | 143.50 |
| April, 1923.. | 39 | 8,444.75 | 216.53 |

# Activities of the Trade

Devoted to News of the Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

### Westinghouse Electric Earns Twice Its Dividends

The net income of the Westinghouse Electric & Manufacturing Company for the year ended March 31, 1923, was $12,263,485 as shown by the company's annual report. The dividend requirements were $6,033,428, so that over twice this amount was earned and more than $6,000,000 added to the surplus. Gross sales for the year were $125,000,000, which represents an increase of $25,000,000 over the sales of last year. The cash position of the company is a strong one, the current assets totaling over $106,000,000 and the current liabilities less than $17,000,000.

"The bookings of new business steadily increased during the year," states Guy E. Tripp, chairman of the board of directors, "and the value of unfilled orders at the close of the year was $61,914,237, as compared with $50,740,696 at the close of the previous year.

### Three Important Western Jobbers Consolidate

The Wesco Supply Company, St. Louis, wholesalers of electrical goods, has purchased the business of the Electric Supply Company, Memphis, and the Gulf States Electric Company, New Orleans. The Wesco Supply Company has recently increased its capital to provide funds for the purpose of purchasing these two companies.

J. L. Buchanan, president of the Wesco Supply Company, will continue as president of the company and will be in active charge of the St. Louis property. W. R. Herstein, vice-president of the Electric Supply Company, will become vice-president of the Wesco Supply Company and will be in charge of the properties in Memphis and New Orleans.

The three properties will be operated as separate and independent units and there will be no change in personnel of office, warehouse or traveling forces. All three will remain General Electric distributors and will continue to handle the products of those manufacturers to whom their respective trades have become accustomed. With slight modifications of territorial limits, so as to conform to economic shipping conditions, the only result of the consolidation will be a common ownership, a greatly increased purchasing power and a stock-interchange arrangement which will give customers the benefit of all three warehouse stocks.

### Warner Elevator Expands

The Warner Elevator Manufacturing Company has completed a large addition to its plant at Cincinnati which gives it a main shop length of 500 ft., 200 ft. in width, two stories and basement. This addition, it is said, makes this the second largest factory in the world for the exclusive manufacture of electric passenger and freight elevators.

A traveling crane in the new south wing connects the railroad spur with the main bay and eliminates most of the trucking to and from the freight cars. A rather unusual problem was recently solved when the 165-ft. elevator test tower was moved bodily to a new location to avoid interference with the main crane track.

### Trumbull-Vanderpoel and Plainville Agreement

The Plainville Electrical Products Company, Plainville, Conn., has entered into an agreement with the Trumbull-Vanderpoel Company, Bantam, Conn., manufacturer of electrical switches, etc., to take over the business which the latter company had on its books covering switchboards and panelboards only.

The Trumbull-Vanderpoel Company has discontinued the manufacture of switchboards and panelboards and is now devoting its entire facilities to the manufacture of inclosed switches and switch parts.

The statement in the ELECTRICAL WORLD of May 12, saying, "The growth of the inclosed-switch business of the Trumbull-Vanderpoel Company has led to an agreement with the Plainville Electrical Products Company whereby the latter will assemble and market this portion of the Bantam company's output," is therefore in error.

### Combustion Engineering Plants at Full Production

New plants of the International Combustion Engineering Corporation are at full production and earnings are in excess of $1,000,000 annually. Business since the first of the current year has been at record figures, both in this country and abroad, the monthly average being in excess of $1,000,000. It is said that this increase is not due entirely to recent developments in burning coal in pulverized form, but also to the fact that business in mechanical stokers is larger than ever.

Business so far in May indicates that the company is having the largest month in its history. Unfilled orders on hand are in excess of $7,000,000, sufficient to keep plants busy at capacity for a full year.

### New Copper and Brass Wire Mill for Anaconda Company

The American Brass Company, subsidiary of the Anaconda Copper Company, has started work on a new mill at the Kenosha (Wis.) branch for the production of copper and brass wire. This mill will constitute a new department at this plant.

The building will be of brick and steel, two stories, 200 ft. x 600 ft., estimated to cost $600,000.

### Pelton Water Wheel Order

The Pacific Gas & Electric Company has awarded a contract to the Pelton Water Wheel Company for furnishing three 48-in. butterfly valves for installation at its Coleman power house. The working head for each of these valves is 470 ft., and they will be equipped for both hand operation and electric motor operation.

The electrical equipment is also arranged for remote control.

### Pittsburgh Transformer Company Making Extensive Additions

A survey of the expansion program now being carried out by the Pittsburgh Transformer Company, Pittsburgh, shows an addition, 80 ft. x 120 ft., being constructed to the Adams Street plant; additional property purchased for a new plant, replacing the old Bayard Street plant, covering an entire city block, contracts for which have been let and started, and property purchased at Metropolitan and Juniata Streets costing $24,000, which will be used for extensions.

When these improvements are completed the company will occupy four city blocks, three blocks covered by its own buildings, and the fourth block, consisting of the River plant, being occupied under lease. The new buildings will be of steel construction with glass sides and buff-brick trimmings of the same general appearance as the Juniata plant.

### Apex Appoints European Manager and Educational Director

Among the recent important appointments made by the Apex Electrical Distributing Company, manufacturer of home appliances, Cleveland, are those of A. L. Zollner as European sales representative and R. E. Palmer as educational director.

Early this month Mr. Zollner sailed for London, where he will establish his headquarters. He was formerly sales manager in foreign countries for the Singer Sewing Machine Company and director of the Willys Export Corporation's activities in the Far East.

Mr. Palmer is at work on a standard form of education for the company's retail salesmen and also a special course for teaching field managers their duties. It is planned to have these courses arranged in time for the company's Cleveland convention, after which it is intended to place a standard course in effect in all the large cities.

### National Conduit Financing Plan

The protective committee representing the holders of the first-mortgage 6 per cent ten-year bonds of the National Conduit & Cable Company has announced that it has received an offer from a responsible party to buy all of the bonds deposited with the National City Bank at a price of $700 net cash for each $1,000 bond. The committee, which consists of Charles E. Mitchell, James H. Perkins and W. O. Gay, has sent a letter to all holders of the bonds outlining the terms of the offer. An extract from the statement of the committee says:

"The undersigned committee has received an offer from a responsible party to buy all first-mortgage 6 per cent ten-year sinking-fund gold bonds of the National Conduit & Cable Company, Inc., which are deposited with the National City Bank of New York, 55 Wall Street, New York City, on or before Tuesday, June 5, 1923, at 70 cents on the dollar of principal, without interest; that is, at $700 net cash for each $1,000 bond, with the coupon due Oct. 1, 1921, and all subsequent coupons attached, payable at said bank, in New York funds, on or before June 20, 1923, provided that if less than 70 per cent in amount of the total issue of said bonds should be deposited with said bank on or before said fifth day of June, 1923, the party making the offer will have the right either to purchase at same price the amount of bonds which has been deposited or to withdraw the offer and refuse to take any bonds."

### Western Electric at Tacoma, Wash., Moves to Larger Quarters

The Western Electric Company at Tacoma, Wash., has recently acquired a new location, moving from 762 Commerce Street to 1511 "A" Street, where full stocks are carried. This new location contains about 2,500 sq.ft. with trackage facilities. The new quarters are up to date in every detail. According to F. N. Cooley, sales manager of the Seattle office, the outlook for electrical business in the Pacific Northwest territory is extremely good and the total year's business should be approximately 60 per cent above that of 1922.

### Granby Consolidated Absorbs Allenby Copper

At a meeting of the directors of the Granby Consolidated Smelting and Power Company last week the company took over control and 90 per cent ownership of the Allenby Copper Company. At the same time D. C. Jackling, August Heckscher, W. H. Coverdale and H. G. Moulton were elected directors of Granby.

The Allenby Copper Company has $800,000 cash in its treasury and General Manager Munroe will immediately start active operations at the Allenby property. Granby is producing close to 3,000,000 lb. of copper a month. Operations at Allenby will add about 20,000,000 lb. a year, making a total annual output of both companies somewhat over 50,000,000 lb. of copper a year.

Col. J. T. Crabbs was elected president of the company to succeed W. H. Nichols.

### General Electric April Business Estimated at $31,000,000

General Electric bookings of new business for the month of April are estimated at $31,000,000. Since Jan. 31 bookings have been at an annual rate of approximately $360,000,000.

Bookings for the first quarter of 1923 were $80,010,045. General Electric entered the current year with approximately $76,000,000 of unfilled orders, which means that, with business booked since Jan. 1, the company had to date approximately $190,000,000 of new business to work on. In the first four months of 1923 goods billed were running at an average of about $20,000,000 a month.

**The Electric Lamp Lock Company,** Kalamazoo, Mich., recently organized to manufacture locking devices for electric light service, is considering plans for the establishment of a plant, estimated to cost about $80,000. The company's products have recently been made at the plant of the Grubber & Smith Manufacturing Company, Jackson, Mich., A. M. Grubber of the latter organization is president of the new company.

**The Connecticut Telephone & Electric Company, Inc.,** Meriden, Conn., announces the appointment of James A. Bennett as sales manager. He succeeds Charles E. Stahl.

**The Gleason-Tiebout Glass Company,** 200 Fifth Avenue, New York City, reports several important orders for its lighting equipment, among which is a large shipment to the new million-dollar high school building in Ottumwa, Iowa, and to the Standard Oil Company of New Jersey's new office building at Baltimore.

**The Walker Vehicle Company,** State and Eighty-seventh Streets, Chicago, manufacturer of electric trucks, announces the removal of its Atlanta office, P. C. Pomeroy in charge, from 926 Hurt Building to 1012 Atlanta Trust Building.

**The Hoover Suction Sweeper Company,** North Canton, Ohio, reports its April business as record-breaking. Volume of shipments during the first two weeks of May indicates that May will show a 20 per cent gain over April.

**The Johns-Manville Company** is moving its big plant out of Milwaukee to Waukegan, Ill. The company has dismantled its machinery and is moving it to the Illinois plant and will allow the Milwaukee buildings to remain idle for the present. This company employs upward of three thousand men and expects to take the majority of its employees with it to the new location.

**The Dryden Rubber Company,** Chicago, announces the appointment of H. E. Lavelle as direct factory representative in Eastern territory for its insulating-tape department. Headquarters are at 15 Park Row, New York City.

**The Gibb Instrument Company,** Bay City, Mich., manufacturer of electric welding equipment, has been appointed distributor of the General Electric Company's arc-welding electrodes in the Middle West.

**The South Norwalk Electric Works,** South Norwalk, Conn., plan to build a two-story addition in the near future.

**The Peterson Storage Battery Company,** 323 South Lafayette Street, South Bend, Ind., has awarded a contract for a one-story addition to cost $30,000.

**The Domestic Electric Company,** 43 Warren Street, New York City, has acquired a portion of the building at 21 Murray Street, under lease, for the establishment of a new works.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

An agency is desired in Panama (No. 6,487) for radio receiving apparatus and small lighting and power plants operated by internal-combustion engines.

An agency is desired in San Juan, Porto Rico (No. 6,478), for lighting fixtures, etc.

An agency is desired in Cape Town, South Africa (No. 6,481), for household electrical appliances, etc.

An agency is desired in Panama (No. 6,482) for electrical materials used in building construction.

The following inquiries have been received by the Philadelphia Commercial Museum, which will furnish names and addresses of the inquirers to any one desiring them and mentioning the number given: A party in Durango, Mexico (No. 40,677), desires information concerning a moving-picture projector and generator to supply electricity for same and for from six to eight lamps. Representation is desired in Havana, Cuba (No. 40,678), for refrigerating and ice-making machinery. Parties in Popayan, Colombia (No. 40,687), desire pamphlets and literature covering small electric motors, lighting plants driven by water power, water-power machinery and also all kinds of electrical supplies and accessories and raw and prepared mica. Parties in Maracaibo, Venezuela (No. 40,649), are desirous of making connections with manufacturers of electrical supplies, automobile supplies, etc. Parties in Turin, Italy (No. 40,653), would like to represent American manufacturers of filaments for incandescent lamps, carbon filaments, tungsten wire and rods, molybdenum wire and rods, borated copper-clad wire and discontinuous tungsten coils for ½-watt lamps. A party in St. Martin, French West Indies, would like to receive catalogs and prices on ice-making and refrigerating machinery, moving-picture machines, telephone and telegraph material, etc. An agency is desired in Santa Clara, Cuba (No. 40,693), for electric lighting fixtures, incubators and brooders, ventilators, etc. A firm in Osaka, Japan, would like to get in touch with manufacturers of electrical apparatus, motor cars, farming tools, etc.

THE GENERAL SUGAR COMPANY, Havana, Cuba, operating thirteen large sugar estates, would like to receive catalogs from manufacturers of sugar-mill machinery, including steam-boiler plants; electrical machinery, including motors, generators; also equipment for power plants, railroad supplies, including locomotives, etc.

PROPOSED ELECTRIC SYSTEM FOR HUTT VALLEY, NEW ZEALAND.—The proposal of the Hutt Valley Electric Power Board to appropriate £200,000 for the installation of an electric system in the Hutt Valley district has been approved by the ratepayers in the district. Energy to the amount of 2,000 kva. is to be supplied from the hydro-electric plant at Mangahao.

## New Apparatus and Publications

WASHING MACHINE. — The Turbax Corporation, 54 West Twenty-first Street, New York City, has developed a washing machine "Turbax," which can be placed in a stationary tub, wash boiler or bathtub.

SAFETY-SWITCH TERMINAL COVER. —The Square D Company, Detroit, has brought out a new porcelain safety-switch terminal cover.

WASHING MACHINE.—A new washing machine, "Hydro-Vac," has been placed on the market by the Altorfer Brothers Company, Peoria, Ill.

VERNIER ADJUSTER. — The Walbert Manufacturing Company, Chicago, has developed a new vernier adjuster, known as the "Univernier."

VACUUM CLEANER. — A new electric vacuum cleaner, the "Magnetic House Cleaner," has been brought out by the Birtman Electric Company, Department M-32, Chicago.

ELECTRIC GLUE POT. — The Rohne Electric Company, 2434 Twenty-fifth Avenue South, Minneapolis, has placed on the market an electrically heated glue pot, known as "Sta-Warm."

WIRE INSULATION STRIPPER. — A tool for stripping the insulation from the ends of electric wires where connections are to be made, known as the "Bard-Parker" wire insulation stripper, has been developed by the Bard-Parker Company, Inc., 37 East Twenty-eighth Street, New York City.

INSULATION TESTER.—James G. Biddle, 1211-1213 Arch Street, Philadelphia, has issued pocket manual No. 1010, entitled "Concerning Insulation Testing with Special Reference to the Meg."

TRIPLEX AMMETER. — The Roller-Smith Company, 233 Broadway, New York City, is distributing bulletin No. 30, describing its triplex ammeter for three-phase alternating circuits, recently developed by the company.

WOOD PIPE. — The Continental Pipe Manufacturing Company, Seattle, Wash., has issued catalog No. 18, entitled "Continental Pipe Used the World Over," which describes and illustrates its products, including wire-wound wood pipe, continuous-stave wood pipe, "creo-wood" flume, etc.

ELECTRIC HOME REFRIGERATOR.— An electrical air refrigerator, "Odin," a new development of refrigeration, has been brought out by the Automatic Refrigerating Company, Inc., Hartford, Conn.

## New Incorporations

THE HAW CREEK WATER & LIGHT COMPANY, Haw River, N. C., has been incorporated with a capital stock of $10,000 to supply water and electricity in Haw Creek Valley and Argo Gardens and vicinity. The incorporators are George W. Craig, Robert H. Brown and Garland A. Thompson.

THE CUSTER COUNTY ELECTRIC COMPANY, Westcliffe, Col., has been incorporated with a capital stock of $25,000 by C. B. Beardsley, George L. Beardsley and Lee C. Mercier.

THE CORTEZ (COL.) LIGHT & POWER COMPANY has been incorporated by Robert W. Bryce, E. E. Johnson and A. A. Cowling. The company proposes to install and operate an electric plant in Cortez.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

PHIPPSBURG, ME.—Plans for the proposed feldspar grinding plant to be built by the Basin Quarries, Inc., Portland, to cost about $65,000, include a power house.

BOSTON, MASS.—The Boston Elevated Railway Company contemplates the construction of an electric power plant at 696 East First Street, to cost about $200,000.

HOLYOKE, MASS. — The Farr Alpaca Company has plans for a one-story power plant at its mill and will take bids at once. S. M. Greene Company, 293 Bridge Street, Springfield, Mass., is architect and engineer.

HOLYOKE, MASS.—The Holyoke Water Power Company is planning to install an electric generating plant of from 3,600 hp. to 4,000 hp. at the No. 2 overflow. The installation will be of the automatic type.

MIDDLEBORO, MASS.—Plans are being prepared for the construction of a municipal hydro-electric plant, at the Mattock dam, to cost about $35,000. H. M. Merrill & Company, Boston, are engineers.

MERIDEN, CONN. — Plans are under consideration for extensions to the Connecticut Schools for Boys, including a power house to cost $50,000; building for laundries, $150,000, and dormitory building, $150,000. E. S. Boyd is superintendent.

## Middle Atlantic States

GLENS FALLS, N. Y.—The Fort Miller Pulp & Paper Company will install electric power equipment in connection with the rebuilding of the portion of its plant recently destroyed by fire.

NEW YORK, N. Y.—The Texas Company, 17 Battery Place, plans to install electric power equipment in connection with the erection of additional units at its oil-refining plant in Wyoming, to cost about $2,000,000.

PHILADELPHIA, N. Y.—The Antwerp (N. Y.) Light & Power Company contemplates a hydro-electric development of 1,000 hp., under 60-ft. head, on the Indian River here, to cost about $150,000. The work will include a dam, power house, tailrace and generating equipment.

ROCHESTER, N. Y.—Staub & Son, Inc., have plans for a one-story power house at their plant.

HACKENSACK, N. J.—Bids will be received by the Hackensack Improvement Commission until June 4 for construction of sewers and pumping equipment, including three electrically operated sewage-pumping stations, together with pumping equipment, etc. The pumping equipment is to consist of A. B. Wood patent trash pumps, motors and switchboards to be of General Electric or other approved make. Lemuel Lozier is engineer of the commission.

KEARNEY, N. J.—Plans are being prepared by the J. G. White Engineering Corporation, 43 Exchange Place, New York City, for a power plant for the local works of the Western Electric Company. Post office address is Arlington.

KEYPORT, N. J.—The Monmouth Lighting Company has been granted permission to issue $200,000 in bonds and $60,000 in capital, part of the proceeds to be used for extensions and improvements.

MORRISTOWN, N. J.—The Jersey Central Power & Light Corporation, recently organized to merge the Morris & Somerset Electric Company, Morristown, Lakewood & Coast Electric Company, Lakewood, and the Commonwealth Electric Company, Summit, contemplates extensions and improvements in the power plants and systems.

NEWARK, N. J.—Electric power equipment will be installed at the plant of the Celluloid Company, 290 Ferry Street, in connection with extensions to cost $130,000.

WALDWICK, N. J.—The Waldwick Coal & Lumber Company is planning to rebuild its power plant and mill, recently destroyed by fire with loss of about $115,000.

DAUPHIN, PA.—J. H. Bucher and W. H. Schubert are organizing the Conewago-Dauphin Electric Company and the Londenderry-Dauphin Electric Company, to install and operate transmission and distribution systems in Dauphin County.

ERIE, PA.—The City Council contemplates the installation of three high-tension and low-tension conduit systems in State and Liberty Streets and the Cherry Street subway, to cost about $28,500. F. G. Lynch is city engineer.

JOHNSTOWN, PA.—The Clarion River Power Company has plans for the construction of its proposed hydro-electric plants on the Clarion River, at Piney, Foxburg and Mill Creek. The Piney station will have a capacity of 44,000 hp., Foxburg of 85,000 hp. and Mill Creek 130,000 hp.

LYKENS, PA.—The East Penn Electric Company has applied for permission to acquire the system of the Lykens Valley Light & Power Company. Negotiations are under way for the purchase of the Pine Grove Electric Company, Pine Grove. Extensions and improvements will be made.

NEW CASTLE, PA.—The Shenango Pottery Company plans to install electric power equipment in connection with a plant addition to cost about $80,000.

PERKASIE, PA. — The Pennsylvania Power & Light Company is negotiating for the local municipal electric plant. It is proposed to convert the plant into a substation.

PHILADELPHIA, PA.—The Philadelphia Rapid Transit Company plans to remodel its Mount Vernon power plant for a substation.

PHILADELPHIA, PA.—Plans are being prepared by the Water Bureau for a power house and electrically operated pumping plant at Richmond Street and Wheatsheaf Lane.

PITTSBURGH, PA.—The West Virginia Power & Transmission Company has been granted permission by the Federal Power Commission to build hydro-electric plants on the Cheat River and plans will be prepared at once for the first station. The cost of the project is estimated at about $75,000,000, including power transmission lines. The present plans provide for a total development of 600,000 hp.

POTTSVILLE, PA.—The Philadelphia & Reading Coal & Iron Company, Philadelphia, plans to install a power plant at its Reevesdale Colliery. The coal mining plant will be electrified.

POTTSVILLE, PA. — Plans are under way for a merger of eighteen electric companies operating in Metal, Lurgan, Beale, Lack, Tell, Dublin, Clay, Milford, Tuscarora, Cromwell, Springfield, Letterkenny, Tod, Fannett, Bratton, Woodbury and Granville Townships. The consolidation will include extensions in the power plants and systems and the ultimate merger with the Penn Central Light & Power Company.

READING, PA.—The Metropolitan Edison Company plans to build a substation at Carsonia, near here.

SALEMVILLE, PA. — Electric power equipment will be installed by the Keystone Coal & Coke Company in connection with the rebuilding of its coal washery and coking plant, recently destroyed by fire, causing a loss of about $100,000.

SCRANTON, PA.—The Scranton Electric Company plans to increase the output of its electric power plant by 25,000 kw. at a cost of about $1,800,000. Additional transmission lines will be erected.

BALTIMORE, MD.—Bids will be received by the Board of Awards, at the office of the City Register, City Hall, Baltimore, until May 31 for furnishing and erecting two 8,000,000-gal. motor-driven centrifugal pumps and electrical equipment for the Druid pumping station, Water Department. William A. Megraw is water engineer.

BALTIMORE, MD.—The Standard Sanitary Manufacturing Company, Bessemer Building, Pittsburgh, Pa., has engaged Samuel Dieacher & Sons, Farmers' Bank Building, engineers, to prepare plans for its proposed new local plant and power house, to cost about $2,500,000.

ELKTON, MD.—The Circuit Court has authorized the North Maryland Electric Company to acquire the property of the Gilpin Falls Electric Light Company, Ellston. Extensions and improvements will be made.

HAGERSTOWN, MD.—The Water Commission is considering the installation of electrically operated pumping machinery and auxiliary equipment in connection with extensions and improvements to the waterworks system, to cost about $2,000,000.

MASON, W. VA.—The Hutchinson Coal Company contemplates rebuilding its power plant recently destroyed by fire, causing a loss of about $70,000.

TIOGA, W. VA.—The Cochran Coal Company plans to install additional electric power equipment at the plant of the Bear Run Coal Company, recently acquired.

WASHINGTON, D. C. — The Potomac Electric Power Company has issued $4,000,000 in bonds, part of the proceeds to be used for the construction of an electric generating plant.

## North Central States

BATTLE CREEK, MICH.—The installation of ornamental lamp standards on Chestnut Street is under consideration.

UNION CITY, MICH.—The Village Council has authorized Holland, Ackerman & Holland, consulting engineers, to prepare plans for the installation of a new municipal electric distributing system.

WATERVLIET, MICH.—Electric power equipment will be installed in the plant of the Watervliet Paper Company.

YPSILANTI, MICH.—The Ford Motor Company contemplates the construction of a power house in connection with its plant here for the manufacture of tractors, automobiles, etc., to cost about $1,000,000.

CLEVELAND, OHIO. — The Cleveland Electric Illuminating Company is asking for bids for a substation to be erected at the foot of East 170th Street, to cost about $750,000. J. C. Spencer, Engineers' Building, is engineer; E. J. Cook, Illuminating Building, is architect.

DOVER, OHIO.—Extensions to the municipal electric light plant are under consideration by the City Council.

LIMA, OHIO—Electric power equipment will be installed at the proposed new lubricating-oil plant at the works of the Lily White Oil Company, recently acquired by the Roxana Petroleum Company, Kansas City, Mo.

LOUISVILLE, KY.—The Kentucky Utilities Company, Marion E. Taylor Building, plans to erect a 33,000-volt transmission line from Rockport to Eckols, to supply electricity to the coal mines at Eckols, to cost about $30,000. The company contemplates erecting a transmission line from Lancaster to Richmond (33 miles), to cost about $150,000. G. T. Bogart is engineer.

OWENSBORO, KY. — Electric power equipment will be installed at the new plant to be built by the Owensboro Clay Products Company.

INDIANAPOLIS, IND.—Extensions and improvements will be made in the electric plants and system of the Indianapolis & Cincinnati Traction Company, to cost about $250,000.

JEFFERSONVILLE, IND. — The Interstate Public Service Company has acquired the property of the Jeffersonville Water, Light & Power Company. Plans are under way for extensions and improvements.

KANKAKEE, ILL.—Plans are being prepared by the Public Service Company of Northern Illinois for the construction of a dam and hydraulic power station at Aroma Park on the Kankakee River, about 4 miles from Kankakee.

CHIPPEWA FALLS, WIS. — The City Council is considering the construction of a municipal electric light plant and dam at the Brunet dam site.

GREEN BAY, WIS. — The Wisconsin Public Service Corporation plans to erect a 5-mile transmission line from High Falls to Ellis Junction. Bids, it is understood, will be asked for the work. Mead & Seastone, Journal Building, Madison, are engineers.

MILWAUKEE, WIS.—Bids will soon be asked for the installation of an ornamental street-lighting system in Shorewood, to cost about $85,000. A. J. Sweet, 531 Grand Avenue, is engineer.

MILWAUKEE, WIS.—The construction of a maintenance building to serve the power plant and other buildings and equipment of the Jones Island sewage disposal plant, now under construction, is under consideration by the Metropolitan Sewerage Commission. The building with equipment will cost about $200,000 and will contain a machine shop. John H. Fowles is secretary of the commission.

WILLMAR, MINN.—The City Council is considering the installation of a light plant in conjunction with the waterworks system, to cost about $150,000. Cory & Le Coque, Aberdeen, S. D., are architects and engineers.

BOLIVAR, MO. — Improvements to the municipal electric light system are under consideration. A. T. Archer & Company, New England Building, Kansas City, are engineers.

CARROLLTON, MO.—The Kansas City (Mo.) Power & Light Company has applied to the Public Service Commission to reconstruct and operate the transmission line from Carrollton to Glasgow.

FULTON, MO.—Bonds to the amount of $50,000 have been voted, the proceeds to be used to complete the water and light plant.

LEBANON, MO.—The Missouri Water Power Company is preparing plans for the construction of four hydro-electric power plants on the Niangua River, with total capacity of about 15,000 hp.

ST. LOUIS, MO. — The Columbia Can Company plans to build a power plant in connection with its new works in the Northwest industrial district, to cost about $500,000.

SWEET SPRINGS, MO.—A special election will soon be called to vote on the proposal to sell the municipal electric light plant to the Kansas City Light & Power Company.

BEULAH, N. D.—The installation of a large electric power plant to supply electricity to a number of towns and villages in this section is under consideration by the Beulah Electric Company.

DEVILS LAKE, N. D.—The Mid-West Power Company contemplates erecting a high-tension transmission line from here to Carrington, a distance of 45 miles, to cost about $55,000.

GENEVA, NEB.—The Blue River Power Company has submitted a proposal to the City Council offering to furnish electricity to the city and to build a distributing plant, to cost about $50,000.

## Southern States

CHARLOTTE, N. C.—The Ornamental Stone Company, 129 Brevard Court, contemplates the construction of a power house in connection with a proposed artificial stone plant, to cost about $70,000.

MICAVILLE, N. C.—The North State Feldspar Company, recently organized, plans to install a power plant in connection with a proposed feldspar mill, to cost about $100,000.

SOUTHERN PINES, N. C.—The Southern Pines Warehouses, Inc., contemplates the construction of a power house in connection with a planing mill and mechanical works.

WALNUT COVE, N. C.—A bond issue of $100,000 has been sold, the proceeds to be used for a municipal electric plant.

SAVANNAH, GA.—The Savannah Lighting Company, recently acquired by Mills B. Lane and associates, is being reorganized. Plans are under way for extensions and improvements to the property.

ORLANDO, FLA.—A bond issue of $630,000 is planned, the proceeds to be used for a municipal electric plant and waterworks system.

SEBRING, FLA.—The Light and Water Department will soon ask for bids for equipment for a municipal electric light and power plant.

NASHVILLE, TENN. — The Tennessee Electric Power Company has issued $2,500,000 in bonds, part of the proceeds to be used for extensions and improvements.

SPRING HILL, TENN.—The City Council is considering the installation of an electric lighting system. Electricity will be furnished by the Southern Cities Power Company.

ATTALLA, ALA.—The Alabama Company will construct an electric power house in connection with the rebuilding of its mining properties recently destroyed by fire, with loss of about $100,000.

SAMSON, ALA.—The Pea River Power Company, Troy, has purchased the local light and water plant. Improvements will be made to the system, to cost about $22,000. A transmission line will be erected from Opp to Samson.

HATTIESBURG, MISS.—Plans for the proposed new mills to be built by the Clyde Lumber Company near Quitman, to cost about $150,000, include an electric power house.

JACKSON, MISS.—The Faust Brothers' Lumber Company will build a power house at its proposed new mill here, to cost about $125,000.

LECOMPTE, LA.—Bids will be received by the Mayor and Board of Aldermen until June 12 for improvements to the electric light and waterworks plant, including two crude-oil engines directly connected to alternators, switchboard, motor-driven air compressor, motor-driven domestic service pump, 8-in. water well, 125,000-gal. concrete reservoir, concrete foundations, new power station, etc. Swanson-McGraw, Inc., United Fruit Building, New Orleans, is engineer.

NEW ORLEANS, LA.—The Todd Dry Docks & Construction Corporation, 25 Broadway, New York, will build a power house in connection with its local drydock and shipbuilding plant, to cost about $2,000,000, with equipment.

BARNSDALL, OKLA. — Electric power equipment will be installed at the oil refinery of the Barnsdall Refining Company in connection with extensions to cost about $200,000.

OKLAHOMA CITY, OKLA.—The Oklahoma Gas & Electric Company has purchased a controlling interest in the Shawnee (Okla.) Gas & Electric Company. It has also acquired the Oklahoma Light & Power Company, Ada, and the Southern Oklahoma Power Company, Byng. The plants will be improved and the transmission lines extended for an interchange of service. New lines will be built.

PAULS VALLEY, OKLA.—The Oklahoma Light & Power Company contemplates erecting a transmission line from its plant at Byng to Pauls Valley, which will eventually be extended to Wynnewood.

PRYOR, OKLA.—The Public Service Company of Oklahoma, Tulsa, has petitioned the City Council for a franchise to supply electricity in Pryor. Under the terms of the proposed franchise the company would take over the city light and ice plant and erect a transmission line to Vinita to supply energy for local service.

DALLAS, TEX.—The Dallas Power & Light Company will soon break ground for a power plant on Griffin Street, to cost about $400,000.

DALLAS, TEX.—Electric power equipment will be installed in the ice-manufacturing and cold storage plant of the Columbia Manufacturing Company, recently acquired by the Southern Ice & Utilities Company.

DEPORT, TEX.—An election will be held May 26 to vote on the proposal to issue $18,000 in bonds to construct a municipal electric light plant.

EL PASO, TEX. — Wells, Stillwell & Spears, Inc., contemplate the installation of a power plant in connection with a proposed cotton-oil mill, to cost about $130,000.

FORT WORTH, TEX.—The Texhoma Oil & Refining Company, Wichita Falls, plans to build a power house in connection with a new gasoline refining plant, to cost about $500,000.

SPEARMAN, TEX.—Bonds to the amount of $12,000 have been approved for the installation of an electric light plant.

## Pacific and Mountain States

NORTH BEND, ORE.—Improvements are contemplated by the Mountain States Power Company, including the construction of a new power house at the Smith mill, to cost about $200,000.

PENDLETON, ORE.—The Pacific Power & Light Company, Portland, plans to build a new local substation, with transmission lines to Kennewick, Wash., to cost about $350,000.

PORTLAND, ORE. — Arrangements are being made by the Portland Railway, Light & Power Company to appropriate $12,000,000 for the construction of its proposed hydro-electric plant in the vicinity of Oak Grove, including transmission lines.

EXETER, CAL.—Plans for the proposed cement manufacturing plant, to be built by John F. Hamburg and associates, to cost about $2,000,000, include an electric power plant.

LOS ANGELES, CAL.—The City Council plans to install an ornamental lighting system on Hollywood Boulevard.

SAN FRANCISCO, CAL.—The installation of an ornamental lighting system on Geary Street in connection with widening of the street is planned.

SAN FRANCISCO, CAL. — The Pacific Gas & Electric Company plans to build a substation in the Vara district, to cost about $100,000, and also one in Berkeley, to cost $65,000.

SAN FRANCISCO, CAL. — The Pacific Gas & Electric Company has secured a fifty-year license from the Federal Power Commission for the Mount Shasta Power Corporation, a subsidiary, for Pit No. 3 unit and a preliminary permit for two and one-half years for Pit No. 4 unit for the same company, both projects being on Pit River. These projects include a storage reservoir, created by a 100-ft. dam and a 4-mile pressure tunnel, to supply water to a 99,000-hp. plant, operating under a head of 307 ft. Below this plant a diversion dam with a 3-mile pressure tunnel will be built to supply a second power house of 53,000 hp. Electricity will be transmitted by a 220,000-volt transmission line through the Hat Creek plants to Cottonwood. Three more plants are contemplated on the Pitt River.

SANTA CRUZ, CAL.—The installation of an ormental lighting system in the business district is under consideration. James K. James is city engineer.

CANANEA, ARIZ. — The Las Chispas Mines Company, Arizpe, plans to build a power plant at its properties, to cost about $200,000.

## Canada

VANCOUVER, B. C.—Preparations are being made by the British Columbia Electric Railway Company for the erection of a transmission line from West Vancouver to Britannia Beach, a distance of 25 miles. The proposed line will supply electricity to the mines of the Britannia Mining & Smelting Company, which has contracted for about 5,000 hp.

WOODSTOCK, N. B.—The power house of the Woodstock Electric Railway, Light & Power Company was recently carried down the St. John River by a flood.

AMHERST, N. S.—A bylaw to secure hydro-electric power from the Economy River will be submitted to the rate payers.

CLIFFORD, ONT.—The rate payers have proposed a bylaw authorizing the construction of an electric light plant at Elora.

TIMMINS, ONT.—The Northern Canada Power Company contemplates building a hydro-electric plant at Ka-Ka-Ke Rapids on the Des Quinze River, where it is estimated that 100,000 hp. can be developed. The initial development, it is understood, will be about 20,000 hp. The cost of project is estimated from $3,000,000 to $4,000,000. Vielé, Blackwell & Buck, 49 Wall Street, New York City, are engineers.

ST. LAMBERT, QUE.—Improvements are contemplated to the electric lighting system, including a new intake to the power house.

SHERBROOKE, QUE. — A bylaw has been approved by the rate payers authorizing improvements to the gas and electric systems to cost about $125,000.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued May 1, 1923)

1,453,529. COMPOUND REGULATING SET FOR INDUCTION MOTORS; W. Seiz, Baden, Switzerland. App. filed Nov. 3, 1921. Auxiliary equipment enables speed control of induction motors above and below synchronism.

1,453,555. ELECTROMAGNET AND CONTROL THEREFOR; G. E. Stack, Ballston Spa, N. Y. App. filed Dec. 21, 1920. Control operation of circuit magnetically.

1,453,574. ELECTRIC WATER HEATER; Z. Trotzer, Budapest, Hungary. App. filed Nov. 1, 1921. Used in direct connection with water supply pipes.

1,453,584. DEVICE FOR AMPLIFYING TELEPHONE CURRENTS AND OTHER ELECTRIC OSCILLATIONS; J. Blankenburg, Berlin, Germany. App. filed June 17, 1919. Armature of a magnetic system coupled to microphone.

1,453,590. PLUG-RECEIVING WALL OUTLET; W. S. Mayer, Philadelphia, Pa. App. filed June 22, 1921.

1,453,595. MANUFACTURE OF INCANDESCENT ELECTRIC LAMPS AND SIMILAR ARTICLES; L. E. Mitchell and A. J. White, Cleveland, Ohio. App. filed Aug. 3, 1920. Tipless lamps.

1,453,602. LIQUID-LEVEL INDICATOR; D. R. Price, Newtonville, Mass. App. filed Feb. 13, 1920. Electrically indicating levels at points remote from liquid.

1,453,612. SELECTIVE RECEIVER; R. L. Williams, Newton, Mass. App. filed Nov. 8, 1917. For receiving signals transmitted under water.

1,453,610. ELECTRIC HEATER FOR WASHING MACHINES; C. P. Russell, Brandon, Manitoba, Canada. App. filed Jan. 7, 1922. Heating element placed in bottom of reciprocating plunger-type washer.

1,453,682. RHEOSTAT; L. Kebler, Bronxville, N. Y. App. filed Dec. 20, 1920.

1,453,699. METHOD FOR SEPARATING MAGNETIC MATERIALS; O. Brophy, Philadelphia, Pa. App. filed Sept. 28, 1921. Heating of metals renders one temporarily non-magnetic.

1,453,724. GRID LEAK; E. L. Powell and C. E. Motto, Washington, D. C. App. filed June 26, 1922. Construction of grid leak having permanent characteristics.

1,453,774. HIGH TENSION CUT-OUT SYSTEM AND THE LIKE; F. C. Van Etten, Chicago, Ill. App. filed Jan. 9, 1920. Method of mounting equipment on transformer poles.

1,453,791. POST AND COVER CLAMP AND SEAL; W. E. Gossling, New York, N. Y. App. filed July 30, 1920. For storage-battery terminal.

1,453,793. ELECTRICAL CONNECTION; V. C. Hamister, Cleveland, Ohio. App. filed June 30, 1921. Pigtail for carbon brushes.

1,453,794. ELECTRIC LIGHT FIXTURE; J. W. Hancock, Denver, Col. App. filed April 18, 1922. Globe-inclosing bulb is combined with reflector.

1,453,817. ELECTRIC COUPLING FOR CARS; H. H. Westinghouse, New York, N. Y. App. filed July 5, 1918.

1,453,821. TELEPHONE SYSTEM; G. A. Yanochowski, Chicago, Ill. App. filed June 20, 1921. Automatic ringing systems.

1,453,827. ELECTRIC LAMP SOCKET; R. B. Benjamin, Chicago, and P. D. Phillips, Elmhurst, Ill. App. filed April 21, 1920. Method of locking lamp in socket.

1,453,829. RHEOSTAT; G. W. Camp, Mount Vernon, N. Y. App. filed Jan. 10, 1921. Theater dimmer.

1,453,832. ELECTRIC HEATER; E. C. Donaldson, Highland Park, Mich. App. filed Nov. 22, 1920. Heating appliance that can be used like a hot-water bottle.

1,453,858. POWER-DEVELOPING APPARATUS; H. F. Schmidt, Pittsburgh, Pa. App. filed July 21, 1910. Combination of two Diesel engines, one generator and two motors for three-screw propeller drive.

1,453,860. ATTACHMENT DEVICE FOR ELECTRIC FIXTURES; J. E. Watson, Philadelphia, Pa. App. filed May 26, 1922. Auxiliary connection for other units.

1,453,888. SPIRIT LEVEL; W. E. Winner and C. C. Patterson, Lowell, Mass. App. filed Feb. 16, 1921. Electrically lighted.

1,453,889. TIRE VULCANIZER; E. J. Rohne, Minneapolis, Minn. App. filed Jan. 8, 1921. Electrically heated and controlled by thermostat.

1,453,911. AUTOMOBILE SIGNAL; N. Browne, Chelan, Wash. App. filed March 26, 1920. Rear direction signal.

1,453,980. ATTENUATION EQUALIZER; R. S. Hoyt, Brooklyn, N. Y. App. filed June 29, 1918. System for telephonic transmission of speech.

1,453,982. ELECTRICAL RECEIVING OR REPEATING APPARATUS AND METHOD OF OPERATING THE SAME; B. W. Kendall, New York, N. Y. App. filed Sept. 13, 1915. Repeaters for submarine cables.

1,454,005. REGULATING TRANSFORMER; N. Wenzel, Twin Falls, Idaho. App. filed Feb. 10, 1921. System of dimming theater lights.

1,454,011. SYSTEM FOR ATTAINING UNIFORM ATTENUATION; O. B. Blackwell, Garden City, N. Y. App. filed June 29, 1918. Transmission system over which telephonic or multifrequency signals are transmitted.

1,454,017. REEL; M. P. Holmes, Claremont, N. H. App. filed Nov. 20, 1916. Gathering reel for mining machines.

1,454,022. THERMALLY CONTROLLED SWITCH; G. H. Whittingham, Baltimore, Md. App. filed July 10, 1922. For starting and stopping alternating-current motors.

(Issued May 8, 1923)

1,454,030. RHEOSTAT; R. B. Austrian, New York, N. Y. App. filed July 14, 1922. Electron tube-filament resistor.

1,454,033. CHARGING RACK; F. T. Baird, Blue Island, Ill. App. filed Oct. 24, 1921. For electric cells or batteries.

1,454,056. ELECTRIC TOASTER; H. Krueshcld, New Washington, Ohio. App. filed March 20, 1922. Sides turned by knot placed on top.

1,454,078. STORAGE-BATTERY ELECTROLYTE; E. J. Rueb, Oklahoma, Okla. App. filed Jan. 28, 1921. Electrolyte composed of two ounces of aluminum-potassium sulphate per pint of hard water.

1,454,085. ELECTRIC INDICATOR FOR VIBRATIONS OF THE AIR; E. A. Sperry, Brooklyn, N. Y. App. filed Jan. 27, 1917. Consists of long slender gas flame affecting sensitive electric apparatus.

1,454,092. SYSTEM OF ELECTRICALLY TRANSMITTING SIGNALS; H. E. Warren, Ashland, Mass. App. filed April 15, 1918. Range signaling for battleships.

1,454,123. ELECTRICALLY OPERATED OIL CUP; R. R. McClure, San Francisco, Cal. App. filed Oct. 20, 1921. Remote-controlled.

1,454,137. SYNCHRONIZED MACHINE GUN FOR AIRPLANES; O. A. Ross, New York, N. Y. App. filed Sept. 14, 1918.

1,454,147. LIGHT SUPPORT; T. G. Berman, Antigo, Wis. App. filed Sept. 8, 1920. Movable arm supports socket and shade.

1,454,157. PHONOGRAPHIC RECORDING AND REPRODUCING SYSTEM; H. C. Egerton, Ridgewood, N. J. App. filed July 19, 1918. Electromagnetic reproducing and recording means with amplifier.

1,454,158. MEANS FOR RINGING OVER MULTIPLEX TRANSMISSION CHANNELS; L. Espenschied, Hollis, N. Y. App. filed July 29, 1919. Means whereby ringing and other signals may be transmitted for each carrier channel.

1,454,159. MEANS FOR RINGING OVER MULTIPLEX TRANSMISSION CHANNELS; L. Espenschied, Queens, N. Y. App. filed July 30, 1920. Employs carrier currents.

1,454,166. INSULATION-SMOOTHING DEVICE; J. A. Heany, New Haven, Conn. App. filed April 10, 1919. For wires having rectangular cross-section.

1,454,195. PHONOGRAPH MOTOR; E. J. Tomlinson, Newark, N. J. App. filed May 20, 1920. Motor directly on record table shaft.

1,454,219. OZONE GENERATING APPARATUS; R. Goedicke, Berlin-Schöneberg, Germany. App. filed Feb. 28, 1920.

1,454,247. DESK STAND; R. H. Manson, Rochester, N. Y. App. filed March 12, 1920. Telephone stand for automatic system.

1,454,289. LIGHTNING ARRESTER; L. M Klauber, San Diego, Cal. App. filed Dec. 3, 1919. Resistance type.

1,454,296. CONTACT RAIL FOR ELECTRIC TRACTION; H. Parodi, Paris, France. App. filed June 15, 1922. Protecting guard placed over rail.

1,454,307. RADIO TELEGRAPHY; A. L. Anderson, Palo Alto, Cal. App. filed Dec. 23, 1919. Single-wave radio signaling system.

1,454,328. RECEIVING ARRANGEMENT FOR WIRELESS TELEGRAPHY; A. Messner, Berlin, Germany. App. filed Sept. 3, 1921. Energy transformed and amplified in cathode relay.

1,454,359. TERMINAL FOR ELECTRICAL APPLIANCES; C. H. Werenskiold, Brooklyn, N. Y. App. filed Nov. 4, 1919. For batteries, spark plugs, etc.

1,454,425. RADIATOR AND PROCESS OF PRODUCING SAME; I. S. Chapman, Venice, and C. E. Mort, Rialto, Cal. App. filed July 11, 1921. Electrically deposited metal binds ends of tubes together.

1,454,448. ELECTRIC KETTLE; C. de C. Matulich, Henley Beach, South Australia. App. filed Aug. 22, 1922.

## Publicity Versus Propaganda

PUBLIC service corporations are telling their story to the people as never before. By printed page and by word of mouth managers of utilities are sweeping away misconceptions of a generation as to the ownership, purposes, responsibilities and rewards of the people's savings devoted to the service of their communities along electrical lines. They are telling the man in the street and the woman in the home the meaning of the industry, its growth from experimental beginnings and hazardous nurturing to the present hour and the superb promise of future usefulness. And the public is responding to this policy of cards face up on table, but some still doubt, calling this work propaganda.

Inside the electrical family we know better. The councils of the industry are shot through and through with discussions by executives and employees in groups large and small of the problems of service. How to meet and how to anticipate the public's needs; how to become better acquainted with customers; how to reduce costs and give more and better service for a given outlay—these are the topics of committee meetings and conferences that never get into the newspapers, but which ought to yield local "copy." Honest efforts to do the day's work better comprise these programs from national conventions down, and if there is any industry striving harder to serve civilization fairly and intelligently, its name is yet to be told.

Sinister meanings are attached to the word "propaganda." The people remember some things a long time, and now and then fail to see the difference between the agency of warfare and hidden selfish purposes and the instrument of truth embodied in today's frank and adequate policy of opening an industry wide for inspection and popular information. Now there are two major requirements in utility publicity: Crystal clarity and statement 100 per cent true and a service matching such statements to the uttermost limit of human ability. Straightforward plain-English accounts of what is doing for the mutual benefit of company and people; rock-bottom elementary principles of finance and regulation; Anglo-Saxon sentences about mutual problems, all expressed in a friendly, nothing-is-being-concealed fashion — and then, officers and employees who strive mightily to live up to the implied ideals.

If the daily performance of every utility employee squares with these principles; if courtesy, honesty, loyalty and devotion are enlisted in the campaign, publicity will make friends for utilities, and the suspicion of propaganda, with its whole train of insincere implications and unwholesome reactions upon public relations, will be cast into the discard by enlightened public opinion.

# Reuben B. Benjamin

*A leader in rendering electrical service to the public which is both economical and entirely safe.*

ELECTRICAL conveniences in the home are nowadays accepted by the public as a matter of course and without any realization of the brains and energy that have been necessary to place these things at its disposal. To the effort and ability expended in the development of convenient and safe wiring devices the extent and popularity of the whole electrical industry have, none the less, been in very large measure due, and in this work the name of Reuben B. Benjamin stands in the front rank.

Born in Fulton, N. Y., in 1869, Mr. Benjamin grew up as a farmer and rancher in New York, Illinois, Virginia and South Dakota. On the South Dakota farm he went through the great blizzards of 1887 and 1888 and developed that pertinacity and strength of character that took him to the front in later life. Leaving the farm in order to develop his mechanical bent, he went to Iowa State College at Ames and was one of the three men to whom that college first granted a degree in electrical engineering.

After graduation in 1892 Mr. Benjamin went to Chicago and worked as an electrician. While he was employed by the Commonwealth Edison Company he invented the wireless cluster, a device which perfected and revolutionized the lighting fixture business and practices of that day and made his business successful. Once launched in business, he was successful from the start and the basement shop was succeeded by larger ones until in 1910 the company moved to its present commodious quarters.

The fertility of Mr. Benjamin's brain is shown by the fact that, in addition to the wireless cluster, he has been the inventor of the swivel plug, the "Benco" socket, "Benox" interchangeable devices, two-way plugs, many designs of industrial lighting equipment, safety lighting for oil refineries and places where gases or explosive dusts are present, besides hundreds of wiring improvements, many of which have been generally adopted. He is also a collaborator in the development of "Elexits." In his efforts to promote safety he has co-operated with the National Board of Fire Underwriters, the Underwriters' Laboratories, the National Safety Council and other bodies. He has been a hard-working member of the N. E. L. A. and other electrical societies.

Volume 81 Number 22

## Simplifying and Interpreting Electric Rate Schedules

RATES for electric service have long provided a subject for discussion within the industry and for negotiation with authorities. They have frequently confused customers and at times have proved a serious bone of contention. At best the subject has its complexities, and methods to simplify and interpret are constantly sought.

The average customer is fully willing that the electric company be allowed a fair rate. But in acknowledging the electric rate as "fair" he is likely to have in mind that it is "fairly" understandable as well as "fairly" reasonable. Complicated rate schedules may find justification in accounting theory, but they usually result in added accounting costs as well as added confusion with the customer. The simpler the rate itself the better. However, the lay public has seen enough graphical representation in ordinary literature to grasp relations indicated by a straight line; so that any means devised to represent rate schedules by straight-line plots to that extent permit the introduction of what are probably more equitable if more complicated rates.

Elsewhere in this issue H. E. Eisenmenger adds to his already well-known contributions to the subject by outlining in a simple manner, free from abstruse mathematics, how this reduction of complex rates to straight lines can be made. He also shows the benefits that are derivable from this practice in analyzing existing rate schedules, projecting new ones, computing accounts for billing purposes and explaining the rate to a customer in doubt.

## Seventy-Million-Dollar Opportunity— Does Merchandising Effort Pay?

IT WAS estimated by *Electrical Merchandising* at the beginning of the year that some twelve and a quarter million electrical appliances would be sold during 1923 to the households of America. This meant a promise of a total sale of electrical merchandise by central-station companies, dealers, contractors and other retailers aggregating over $282,000,000; and from the use of this additional equipment in the home would come a new source of annual revenue to the public utility of $83,000,000. To such proportions has the business in electrical merchandise in this country grown.

These figures represent only the estimated ordinary growth of the business that is coming based on merchandising activities on the scale of the past two or three years. That is the ordinary expected business, the regular goods sold in the regular way. It is a little more business than was done last year, a little less than will be done next year, if history repeats itself. But it is worth while considering—just to dream a dream—what might happen if a little extra effort were applied —if the industry sold six fans, six cleaners, six irons, six of everything instead of five. No one knows, of course, exactly what it would mean—there are not sufficiently accurate data. But on page 1285 of this issue appears a tabulation of estimated sales of the various domestic appliances this year, according to normal expectation, and the energy revenue to be derived therefrom, together with an analysis of what a 20 per cent increase in these figures would be worth to the industry. The estimate is at least worth discussing, and if even approximately correct, it shows roughly a seventy-million-dollar opportunity for the price of a little added effort and a little better planning.

The attention of the entire electrical industry will be focused next week on the annual convention of the National Electric Light Association in New York. There will be much discussion of what the central-station company should do to sell more appliances. Here is one measure of the value of efforts in this direction.

## Nation-Wide Interconnected Superpower Survey

A PLAN of electric generation and transmission with proportions truly great has been worked out by Frank G. Baum, an engineer of wide experience in long-distance hydro-electric transmission. His scheme is outlined briefly in this issue. It involves the utilization of the country's vast water-power resources in a comprehensive interconnected system without jeopardizing the investment already made in large modern steam electric generating stations. He divides the country into twelve regional electric power districts, and if the zones are larger than any heretofore contemplated, it is because Mr. Baum is looking far into the future and after much study has mapped a logical system whose advantages loom greater the more it is studied. There is about it nothing visionary or provincial. It is national in scope, contemplates the transmission of large blocks of power, and is based on experience and surveys in the field. True, some of the transmission distances are quite long, but length of transmission is not generally a determining consideration; dependable economic power supply, good load factor and a large stable market are often more important.

Fortunately, no work of such a magnitude has yet been undertaken, so that there is nothing to be undone. The proposed superpower transmission system of energy trunk lines is merely superimposed on what is already in existence. A cursory examination of the regional zones in the East, for instance, indicates that the scheme is instantly applicable to that section. There is a million and a half hydro-electric horsepower available in Tennessee and half as much in West Virginia within easy transmission distance of the great industrial section in the Ohio Valley. The government's survey has shown the necessity of a superpower system along the Atlantic seaboard from Boston to Washington, and water-power development on a grand scale is the present topic of discussion in engineering and political circles in the Middle Atlantic States. We mention this merely to show the timeliness of Mr. Baum's

scheme and to indicate its practical value. The nation's resources of water power, coal, oil, and gas are known; so are the great power markets. What Mr. Baum has done is to fit one into the other in a masterly fashion, thus indicating the lines along which progress will march. His is a very valuable and far-sighted contribution to the art and economics of electric power transmission and will well repay close study and application.

### A Word About Artificial Lightning

THE brilliant and sensational results obtained with "artificial lightning," reported in the May 19 issue by F. W. Peek, Jr., bring to mind some of the characteristics of the natural phenomenon and their relation to experimental results of this sort. All through the history of power transmission it has turned out that as working voltages went up and the insulation of the lines rose with them there has been on the whole less and less trouble from lightning. In other words, the line insulation has been sufficient to take care of a great many disturbances charged up to lightning. Of course, the fact is well known that only a very small minority of the so-called lightning strokes on the line are at all of the nature of direct hits. Most of them are induced discharges of greater or less severity, sometimes giving rise to savage surge effects on the system. The supervoltages may amount to several times the nominal line voltage, but save in direct strokes do not reach any astonishing figures. As Mr. Peek shows, there is not much above 400,000 volts that occurs in actual practice.

The experimental investigation of lightning discharges has risen to high importance since the initiation of the various projects for superpower lines at working voltages exceeding 200,000. In particular, the effect of lightning discharges on the distribution of stresses over insulating strings is a very vital factor in design. Now, the beauty of the apparatus devised by Mr. Peek in its later stages of development is that a pressure of 2,000,000 volts can be momentarily applied to the line, or any voltage up to that astounding figure. The general method of obtaining these prodigious differences of potential is the charging of a static condenser of great capacity to the necessary voltage and then arranging for its discharge over, for instance, an insulator string so as to simulate anything which nature can show.

Lightning discharges are for the most part known to be of enormously steep wave front, generally nonoscillatory as regards any material part of the energy. By discharging a condenser of adequate size through known inductance and resistance it is obvious that almost any amount of damping or lack of it can be obtained on the wave front, giving approximately any wave shape that may be desired. Incidentally, the rate at which energy is turned loose on the system is enormously great as compared with any rate of output of man's devising, unless possibly the firing of a great coast-defense gun. Therefore with an almost indefinitely large amount of energy as reckoned in kilowatts available, with a wave shape which can be regulated with a good deal of precision, it becomes possible to try out in advance all the critical things which might be supposed to present the practical problems of insulation for superpower lines. The mere feat of getting the apparatus for doing this work is a memorable one. The usefulness which may be attained in the transmission work of the next half century is beyond present measure.

### Railroad Electrification and Power Supply

EVENTUALLY the railroads of this country will be electrically operated. Of that there is no doubt. Meanwhile, however, old-line steam-railroad men are doing all that is possible to prolong the present system by improving the efficiency of locomotives, lowering grades, eliminating curves, and so forth. This, of course, is praiseworthy, but it will not ward off the inevitable. It is well, however, for electrical engineers to recognize the situation and to visualize the immensity of the inertia to be overcome. Two weeks ago Julius Kruttschnitt, in an address before the International Railway Fuel Association, stressed the need of greater efficiency in the use of fuel by the railroads and indicated that thereby a reduction of 13 per cent of expense is possible. For the future, Mr. Kruttschnitt says, the hope for conserving fuel lies in (1) substituting hydroelectric energy for steam, (2) substituting steam turbines or compound condensing engines for simple engines, (3) use of a cheap high-gravity fuel, (4) reduction in weight of Diesel engines sufficiently to permit of their use as locomotive engines, and (5) development of a satisfactory variable-speed transmission gear for coupling the Diesel engine to the driving wheels of the locomotive.

In that he chose electrification first Mr. Kruttschnitt did well, but that electrification depends on water power does not follow. Electricity can be produced in steam generating stations just as cheaply in many instances as from water power, and under certain conditions of load factor cheaper. What the railroads need is not conviction on the necessity of greater water-power development, but conversion to electrification. When this is accomplished they will find that the electric light and power industry is not only prepared to supply all the energy they may need, but at a price that no railroad can afford to ignore. The railroads need never lack for electricity.

In this connection the last two recommendations of Mr. Kruttschnitt may be commended to the thoughtful consideration of the manufacturers of electric railroad equipment. If Diesel engines ever become available for locomotives, electrification will be set back a generation and the manufacturers of electrical equipment will have only themselves to blame. It will be a sad day for them if the "battle of the systems" shall lead to such an outcome.

### Electrical Heat Treatment Assuming Greater Prominence

RENEWED activity in the use of electric furnaces in all sorts of metallurgical operations has followed the resumption of business activity, and it may be well once more to indicate the virtues and limitations of their application in the light of present practices, problems and equipment.

Given the requirements of heat treatment for whatever purpose, two fundamental questions at once arise. First, what will be the over-all cost? Second, is electrical heat worth any more on account of any special bearing on operating and utilization?

As regards the first question, it is fairly easy to determine the necessary B.t.u. to supply the quantity of heat required for delivery to the articles in process. The basic quantities are the unit cost of heat used and the efficiency with which the energy thus provided can be delivered to the work. These calculations are inde-

pendent of the source of heat used, but the electric heat calculations are made more readily and accurately because of the difficulty in determining data when using gas, liquid or solid fuels. Speaking in general terms, the transformation of energy in fuel to heat delivered by furnace resistors is on a par with the thermal efficiency of the best heat engines, and when comparison is made with furnaces using direct heat the real efficiency is about a stand-off. On a thermal efficiency basis, therefore, there is no real reason for deciding at the start that electric heat is unnecessarily expensive.

As regards first cost of installation, many variables occur which make it difficult to fix upon a basis of comparison. The insulation material and quantity of insulation used is generally greater on the electric than on the directly heated furnace, but, on the other hand, when floor space, fuel storage capacity and other auxiliary installation details are considered, again a stand-off is generally reached on cost comparisons.

On the second count of production efficiency and convenience a long line of experience with furnaces for almost every sort of use shows that electric heat possesses superior merits from the standpoint of ease of application and control, flexibility in furnace location, accuracy of measurements, speed of production and uniform quality of product. In many industrial processes the fact that electrical heat can be applied uniformly and controlled accurately has been the deciding factor in its adoption, to say nothing of the advantages that come from the ability to work electric heating in vacuo or in any sort of neutral atmosphere that may be needed. Furthermore, the indirect saving obtained by having all process material turned out with exactly the same quality has been an important reason for the adoption of the electric furnace.

There is still much to be done in electric heating—many other applications to steel treatment would occur if the slightly oxidizing atmosphere in the electric furnace could be eliminated. Radiant and resistance types of heating elements and also furnace insulation are not yet perfected, but every indication points to a still greater increase in the load of electric heat-treating furnaces on the lines of the big central stations.

## Circuit Breakers and Other Switchgear

NOW and again calls come for radical improvements in circuit breakers, improvements that will lessen the cost and space demanded, improve the efficiency of the apparatus and the quality of the break, and in general relieve the art from what one may refer to as the hypertrophy of the switchboard. Now, by and large, the apparatus available from standard makers is of good operative quality. It meets the technical requirements on the whole remarkably well and almost daily advances are recorded; but any one who studies the ensemble of the circuit breakers and other switchgear in a modern station comes to a sudden realization that the tail is wagging the dog, that distribution practice has been built up along lines which have forced the switchboard into undue prominence.

While minor improvements in material and design will undoubtedly be made and will perhaps aid here and there in reducing the absurd overgrowth, anything of sweeping importance in increasing the effectiveness and cutting down the formidable expense of the switchboard must come from new conceptions of efficiency in distribution methods rather than from evolution along lines now well laid out. What would happen if there were given into the hands of an engineering committee not too closely devoted to the exploitation of things as they are the problem of laying out *de novo* the complete electrical system of a city of half a million or a million inhabitants? One could feel very confident that the result of its study would be startling to those who have grown up in the regular evolutionary course of conventional construction. Of course, no such blessed opportunity is likely to fall into the hands of any one in our day—this whole question of relatively inexpensive and efficient switchgear is inextricably bound up with the general problems of distribution. Most of our great systems in this country and elsewhere have just grown, each step being a forward one, but hampered by the whole history of the enterprise, financial and technical. In the matter of switchgear, just as elsewhere, real advance is likely to be slow, but some day there will be an opportunity to break away from tradition and make headway along new lines of progress.

## High-Voltage Insulation Still Baffles Analysis

ONE of the oldest experimental problems in the field of electrical engineering is that of the nature of the processes involved in high-voltage insulation. The question is important from both the practical and the purely scientific standpoint. It is a problem which is receiving increasing attention, and there is constant evidence that trained investigators are being attracted more and more to the wide variety of problems offered in this field. Recent evidence of this is the receipt in this country of German publications of the work of Dr. K. W. Wagner, who, it will be recalled, addressed the A. I. E. E. at the Chicago meeting in the spring of last year. Dr. Wagner's paper emphasized the importance of the influence of temperature on insulation, and he suggested that the process of breakdown is largely if not entirely due to the increasing conductivity of insulation caused by temperature rise. At about the same time there appeared in the ELECTRICAL WORLD an account of the experiments of Steinmetz and Hayden leading to very much the same conclusions, although the experiments were quite different in character.

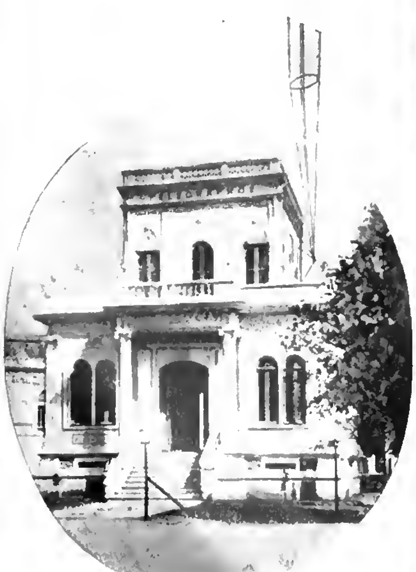
These two sets of experiments do not constitute the first suggestion of the importance of temperature as a factor in the processes leading up to the failure of high-voltage insulation. For a long time the occurrence of hot spots in cables has been noted and has led to the realization that insulation failure does not, in accordance with early ideas, occur as a result of abrupt or disruptive puncture. The important phase of experiments of this character lies, therefore, not so much in the suggestion of a new theory of breakdown as in the new methods that are opened for the further study of the nature of the processes of insulation. The subdivided electrode of Steinmetz and Hayden, on the one hand, and the high-resistance electrode of Wagner, on the other, both offer suggestions for new avenues of study of the behavior of limited regions of the dielectric or insulator. Neither method has been perfected, but each offers good promise of more exact study of this extremely important problem.

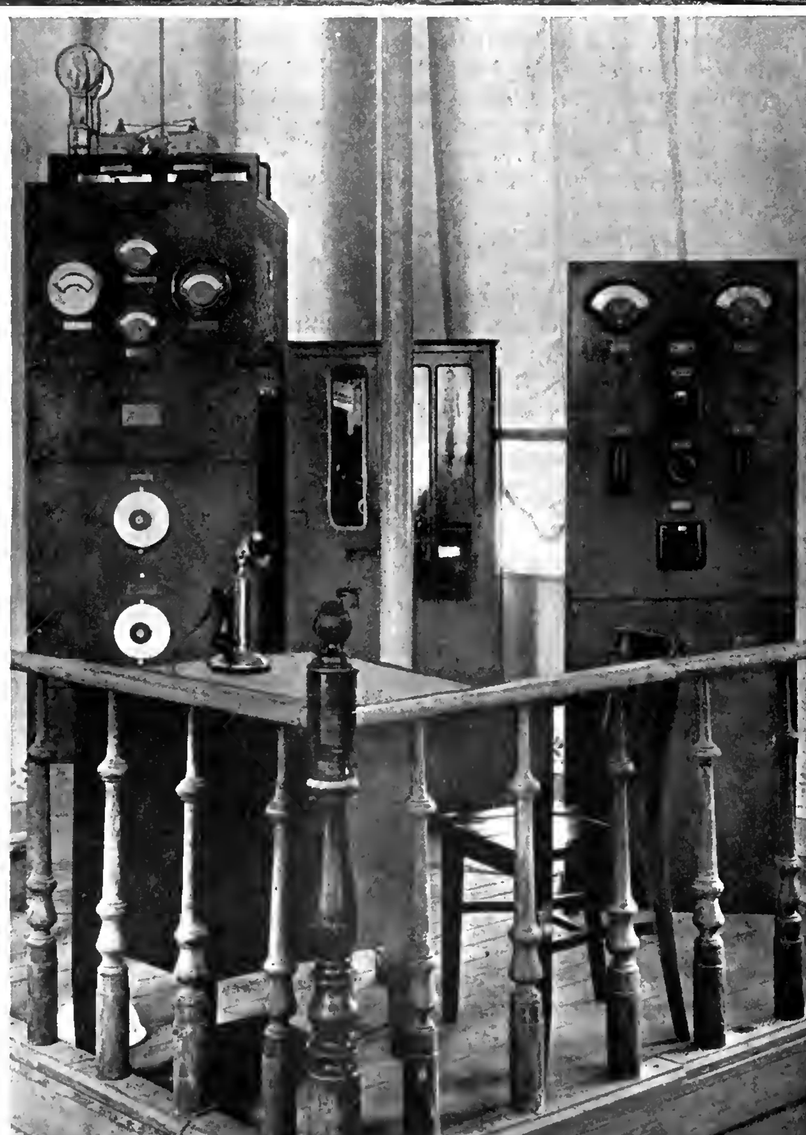
# Rio's Remarkable Radio Station

TO BE heard 8,000 miles is the remarkable record of the radio broadcasting station SPE erected by the International Western Electric Company at the Brazilian Centennial Exposition at Rio de Janeiro.

The antenna, which contributes considerably to the exceptional efficiency of this transmitter, is of a very unusual type. It is a six-wire cage antenna, 500 ft. long, and is suspended from a cable strung between the tops of two mountains, Urca and Babylonia, near the famous Sugar Loaf Mountain. Musical programs were broadcast from this station and were received on a Western Electric 3-A radio receiver and amplified for the enjoyment of thousands of visitors at the exposition by the Western Electric Public Address System.

On Feb. 2 an official demonstration was held, at which a speech delivered by Dr. Sampaio Vidao, Secretary of Agriculture, and military band music were transmitted from Rio and received at São Paulo. Here the Public Address System, installed in a theater, amplified the Rio program for a large audience, in which were the Mayor of São Paulo and many other notables.





# Automatic Plants Aid Western Water-Power Development

## Nine Semi-Automatic Generating Plants, with a Total Rating of 14,655 Kw., Are Now in Operation on Southern California Edison System—Operating Costs Are Reduced Approximately 45 per Cent

By E. R. STAUFFACHER* and GUSTAF CLINWALD†
*Southern California Edison Company*

WHILE attention has been focused on such developments as Big Creek, Pit River, Kern River and other large projects in California because of their spectacular nature, yet notice has not been lacking of the economical operation of some of the older and smaller hydro-electric plants by the use of automatic or semi-automatic control. Because of the greater savings in operating costs many small plants have been changed over from manual to semi-automatic operation and others which will be automatic or semi-automatic are either under construction or planned. There are now in operation in California about fifteen installations of this type with a total capacity of nearly 20,000 kw. It is safe to say that all of these plants would be economically impracticable if it were necessary to employ manual control. Automatic control has been confined so far almost entirely to the smaller plants which were the pioneers of the modern power plants of today. These small plants, with their high operating expense, cannot compete with the lower production costs of the larger plants and would have to be discarded if it were not for the economy brought about by automatic operation. Another factor in their development has been the problem of keeping competent operators. Present-day operators are rapidly assuming an attitude of independence and an air of indifference toward their work. They expect modern city conveniences and even with the best of accommodations do not always show the proper appreciation. With the present high labor turnover it is only logical that automatic apparatus should be meeting with favor in the small and remote hydro-electric plants of the West.

The automatic generating plant is comparatively new, and in the earlier plants most of the apparatus of necessity had to be home-made, particularly that for proper water control where storage capacity was very limited or there was none at all. The manufacturers are rapidly meeting this situation, and it is now possible to duplicate every operation of manual control, even to observing the operating conditions of an automatic station at some distant point. A system of supervisory control has been worked out by means of which over a single pair of wires it is possible to listen in on a distant station and determine the position of circuit breakers, water level, load on the station, hot bearings, etc. The present tendency in the design of these plants is toward the use of induction generators, although most of the plants now in operation are equipped with synchronous generators. The present economic limit of the automatic generating plant seems to be about 5,000 kw., or a limitation to plants where operating costs are relatively high in proportion to fixed charges. In the larger plants with high load factor and relatively

heavy fixed charges per kilowatt-hour, and where the capacity of the plant is such that a shutdown would seriously affect the system it is feeding into, manually controlled plants generally prove more economical and desirable.

### Automatic Plants of Southern Edison

Nine semi-automatic plants, varying in size from 585 kw. to 3,900 kw. and with a total rating of 14,655 kw., are in operation on the system of the Southern California Edison Company. Table I gives the number and capacity of the units in these plants, the operating head, etc. Full automatic operation was not considered necessary, because one man must be on the premises to act as watchman and caretaker and he is available at all times to start up the plant in case of a shutdown from any cause. The problem of changing to semi-automatic operation was primarily one of water control as the plants have little or no storage. Furthermore, in southern California, where water from small mountain streams is used for irrigation, it is necessary that the hydraulic plants be so operated that under no circumstances will water be spilled at the forebay and thereby wasted.

To meet these conditions special water-control equipment has been developed. In case of high water in the forebay the generator will automatically pick up more load, and in case of low water the nozzle on the waterwheel will be slightly closed so that there will be no danger of lowering the water in the forebay to the extent of allowing air to be trapped in the penstock or pressure pipe. In some of the older plants this is accomplished by means of current-balanced relays wired in the nature of a Wheatstone bridge so arranged that fluctuations of the water in the forebay cut in and out suitably arranged resistances. This causes relays to operate at the power house and open the waterwheel nozzle if the water in the forebay is high and close it if the water is low.

The specially designed water-control equipment used at the Sierra plant, the last one to be converted from manual to semi-automatic operation, is shown in Fig. 1, and the wiring diagram in Fig. 3. This newly designed equipment is operating very satisfactorily and will probably be made standard water-control equipment on the Edison system. At this particular station there are two units of 300 kva. each, operating under a head of approximately 700 ft. The storage is very small and the conditions of water control are severe. Roughly, the system is comprised of three essential parts—a motor with limit switch and gearing mounted at the needle valve, a slate panel on which are mounted the necessary relays, etc., and a specially designed float switch installed at the forebay.

To obtain the desired regulation the periods between the operation of the needle valve motor and the duration of an operating period should be roughly a function of the distance between the actual and the desired water level. The motor must move the needle valve in proper relation to the water level, and the action of the needle should be discontinued at any point, provided the water is moving toward the proper level. It will be seen from Fig. 3 that there are two circuits, one comprising a coil of the balanced relay *BR* and the reactance *BI*, and the other the remaining coil of the relay *BR* and the reactance *R*. The core of the reactance *BI* may be moved by means of a knurled nut to facilitate close balancing, and the core of reactance *R* is actuated by the float mechanism. These balanced circuits are energized every two and one-half or five

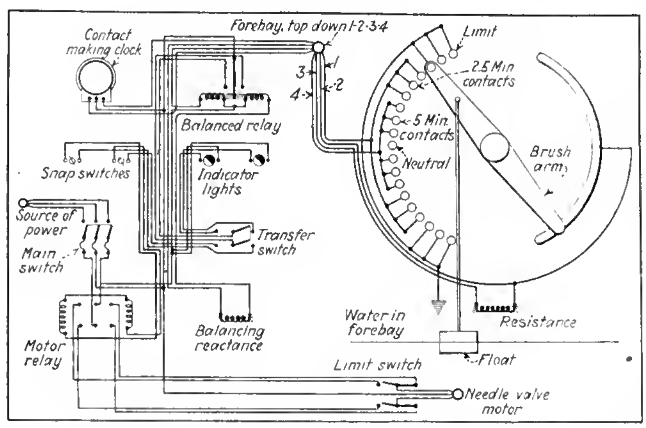

FIG. 3—CONNECTIONS OF ELECTRICAL EQUIPMENT AT FOREBAY AND POWER HOUSE FOR WATER-CONTROL MECHANISM IN SEMI-AUTOMATIC GENERATING PLANTS

minutes by the contact-making clock shown in Fig. 2, or continuously from ground as determined by the position of the float-actuated brush arm *BA*. If upon being energized the circuits are unbalanced by the position of the core in the coil *R*, then the balanced relay *BR* closes its contacts to the left or right and operates the needle valve motor, the motor relay and the limit switch, or gives a visible signal by means of indicating lights as determined by the position of the transfer switch. The

TABLE II—COMPARATIVE ANNUAL OPERATING COSTS OF MANUAL AND SEMI-AUTOMATIC GENERATING STATIONS

| | Estimated Cost 1922 | | | Actual Cost, 1922 | | | |
|---|---|---|---|---|---|---|---|
| Plant | Labor (Chief and Three Operators) | Maintenance (Three-year Average) | Total | Labor | Maintenance | Total | Annual Saving |
| Santa Ana No. 3 | $5,400.00 | $136.58 | $5,536.58 | $2,369.10 | $23.76 | $2,392.86 | $3,143.72 |
| Lytle Creek | 5,310.00 | 121.57 | 5,431.57 | 2,123.50 | 6.68 | 2,130.18 | 3,301.39 |
| Santa Ana No. 2 | 5,400.00 | 195.21 | 5,595.21 | 1,902.05 | 132.57 | 2,034.62 | 3,560.59 |
| Mill Creek No. 1 | 5,340.00 | 188.31 | 5,528.31 | 1,972.29 | 33.87 | 2,006.16 | 3,522.15 |

mechanism for controlling the movement of the core in reactance $R$ is shown in the upper left hand picture in Fig. 1.

Where a plant has more than one generating unit the regulating is done on only one waterwheel and the others are operated at continuous load.

PROTECTION AGAINST TROUBLES

Equipment is provided to protect against troubles developing inside the power house or on the transmission lines. This equipment is arranged so that in case of a short circuit the armature switch is kicked out, which in turn kicks out the field circuit breaker, thus causing the automatic governor trip to operate. Bearing thermostats are provided at the main waterwheel, generator and exciter bearings, and the thermostats and circuit breakers are connected with an annunciator so that the attendant can easily locate the trouble in case of a hot bearing or a switch kicking out. In case of a complete shutdown of a plant it is started up manually and put back on the line by the caretaker. It is felt that the complication necessary to accomplish this result would not be justified in view of the fact that there must be one man on the premises at all times for other reasons.

The equipping of these small plants for semi-automatic operation on the system of the Southern California Edison Company has resulted in marked savings in operating costs, as shown by Table II. Not only have operating costs been reduced, but it has been found that maintenance costs are actually less owing to the smaller use of oil and waste. On the whole, the plants have given more satisfactory operation than when under manual control.

# Fuel Economy and Production Expenses

## Data Are Given for Forty-five Coal Burning Plants Ranging from 10,000 Kw. to 122,000 Kw.—First Part of Analysis Which Will Be Presented in Installments

By ALLEN M. PERRY
*Engineering Editor* ELECTRICAL WORLD

THE many expressions of appreciation of the operating data given in the July 15, 1922, issue of this periodical and the widespread requests for the article led the ELECTRICAL WORLD to solicit similar information from operating companies all over the United States. The response to its inquiries was so much beyond expectations that the data received willl be published in installments as they are compiled and checked, instead of waiting until the entire mass of material is ready for publication. The figures refer to the twelve months ended July 1, 1922.

If the operating conditions are carefully studied and the data properly interpreted, they should be helpful in showing the results that may be obtained by other companies operating under similar conditions. However, the chief interest of the information lies in showing the effect which concentration of power generation, extent of plant utilization, characteristics of coal, price of fuel and labor, etc., have on fuel economy and operating and maintenance expenses. Every engineer recognizes that the costs which are recorded are also affected by plant conditions (modernity, type of equipment, upkeep, etc.), plant management and the human factor involved in labor, but many of these factors are intangible and cannot be incorporated in a table of this kind. Neither can a large expenditure for maintenance be properly spread over a long period in the way it should be. Despite the many factors which influence operating economy and production expenses, it is interesting to observe how closely the results obtained in plants of similar size follow the plant factor and coal characteristics.

To make possible a more intelligent interpretation and study of results several changes were made in the form of this table as compared with the one printed ten months ago. For example, it was considered necessary to rate all stations in the same manner; hence the total installed rating as indicated by nameplates is given. Allowance has not been made for overload capacity, and reserve equipment has been included. Neither has the rating been reduced where there is insufficient boiler capacity, but each reader can make his own interpretation if he will compare the ratings with the figures given in the last two columns.

Last year load factor was given instead of plant factor (net output in kw.-hr. ÷ installed kw. × 8,760), but it is not believed that load factor has as much effect on performance as plant factor, or the extent to which the plant is utilized. The load factor can, however, be easily calculated by any reader who desires to know it.

In all cases it was requested that the amount of fuel burned be expressed in short tons to avoid confusion which arose last year in determining whether the fuel consumption was submitted in short or long tons. The price of fuel per ton was obtained this year so that readers who are studiously inclined may ascertain the plant value of coal containing different amounts of ash and heat content.

The wages paid for labor might also be interesting, but to be of any use it would also be necessary to show how this labor is distributed.

Maintenance expenses have been further subdivided this year into building and structures, boiler plant, prime movers and auxiliaries, generators and electrical equipment, and miscellaneous.

An analysis of the figures will show the value of concentrating power generation and operating at the highest plant factor, although it is surprising to see how one of the smaller plants (No. 57), operating at low plant factor, is holding down its production expenses. The remarkably low total production expense of this plant is due to the fact that the plant is operating with a much smaller force than it would require were

## Operating Economy and Production Expenses of Forty-five Coal-Burning Generating Stations (10,000-122,000 Kw.)

[1] Burns natural gas and coal; coal given is equivalent coal; actual coal burned is 78,586 tons.
[2] Auxiliary to hydro power.
[3] Burns coal and oil.
[4] Boiler plant equivalent to 36,000 kw.
[5] Turbine rated at 20,000 kw. added 11/17/21; 6 boilers 5/27/21.
[6] Energy purchased, 9,297,600 kw.-hr not included.
[7] Burns powdered fuel.
[8] Burns natural gas and coal.
[9] Five months' operation; first turbine and two boilers started 10/16/21; second turbine and two boilers put in service 10/18/22.
[10] Burn coal and oil.
[11] Only 19,250 kw. in use.
[12] Coal price delivered in bunkers.
[13] Installed generator rating is 35,000 kw., but boiler capacity is limited to 20,000 kw.
[14] Include cost of steam to large heating load.
